as the beginning of the " unorganised " period—very
it started earlier—the patient was then 28 You
mber I asked the rhetorical question of what would
happened to the woman patient if her doctor,
ad of asking his hesitant questions, had sent her for
dotherapy Although admittedly our second patient
r more ill than the woman his case could be con
ed as a pointer of the direction the woman's illness
it have taken We may here ask the corresponding
tion of what would have been the fate of this man if,
ad of sending him to specialists and prescribing him
les and bottles of medicine, someone had asked a few
nent questions at the right moment Who knows ?
nyhow, our man settled down and created and grew
mpressive illness involving his whole life Although
superficial symptoms varied and changed, the basic
ture of the illness remained the same and became
er and firmer with the years One aspect of the
s was to play hell with his practitioner, to rub in
and again that he was no good, absolutely useless
cannot exclude altogether the possibility that this
partly a revenge for the doctor s rejection of the
nt's propositions. Although it is not mentioned in
report, we can well imagine that there were quite a
not very pleasant periods for the doctor He asked
help from his specialist colleagues, but what he got
only negative advice That is, he was told what
o do, but he got no help whatever on how he could
his atient. I wonder how many of us—whether
ral practitioners, psychologists psychiatrists or
l workers—would have remained under this irritat
re, as calm and imperturbable and as friendly and
pathetic as *our doctor How many of us would have*
ght of taking down the pharmacopœia and offering
cerely to the patient to choose from it the medicine
inks might help him

was this atmosphere of unshakable friendly sympathy
enabled the patient to make his peace with his bad
useless doctor and to accept his company for all
troubled years of illness, pain, and suffering He has
ously been badly in need of company, and without
doctor he would not have been able to keep fit and
tain a tolerable or perhaps even a not completely
ppy, private life

sum up in this case all the organic illnesses
osed by the patient were rejected one by one but
doctor accepted the pain and the suffering and
tly tried at least to relieve them. This counter
ition of his was in turn rejected by the patient,
perhaps prompted also by his resentment—wanted
ve his doctor bad and impotent The doctor then
d to this last proposition—i e , that he cannot
e the suffering and pain and agreed also to remain
lly and sympathetic On these terms a working
romise was established and patient and doctor
d down to a form of illness acceptable to them both

* * *

w imagine that this patient had been on the list
doctor who—because of his personality—must be
od and helpful man whose apostolic function
els him to try everything in his power to cure his
nts without exception—or mercy

* * *

romised to talk about The Doctor, His Patient and
Illness But really ' the doctor " should have been
plural, for in any difficult case specialists are called
advise This brings in quite a number of new
lications. From now on the patient cannot escape
g that he has got to deal with the whole medical
ssion facing him a single person in concerted
n. This inevitably stirs up reminiscences of his
life, when, as a single child, he had to face the whole
of adults who tried to educate him in their
tolic function It is in this way that the present
situation mobilises all the anxieties animosities, fears and frustrations blind confidence and dire suspicions, of that early age This fact explains why so many patients regress to surprisingly childish methods in their relation to their doctor or doctors—e g to complete subordination, or swearing blindly by the doctor s words , to an almost crazy rebelliousness ridiculing and belittling anything and everything that the doctor proposes , or to a habit of playing off one doctor against the other But behind their unrealistic attitude is always the gnawing fear and the abject dependence They feel that possibly something very important has gone wrong in their body or mind that they cannot put it right by themselves , but that almost certainly this can be done by outside expert help With this help they may survive ; without it they are doomed

* * *

We know that during the initial unorganised " period of their illnesses, patients gradually withdraw from their environment and first create and then grow the illness on their own, out of themselves This period is only poorly understood our psycho analytic methods do not enable us to follow in detail the patient in his struggle with the growing illness In this situation there is as yet no second powerful person present, and certainly no external partner on whom emotions could be transferred and thereby made accessible to our analytic methods But the situation changes fundamentally when the patient reaches the stage of complaining Although his illness is usually still unorganised he now needs, and usually also finds, a partner a superior one, from whom help can be expected on whom emotions can be transferred. Here we analysts are more at home and can use our methods with more confidence, and our ideas may be of some use to the general practitioner in his arduous task

It is equally true however, that we can also learn from the experiences of the general practitioners , for it is only seldom that we see patients in the unorganised state in which the practitioner first encounters them, and we have mostly avoided getting involved with them at this stage On the other hand the psycho analytic process is tantamount to stirring up rigid, settled in attitudes and forms of reaction, and almost every day we witness and have to work with both kinds of transition —from organised to unorganised and from unorganised to organised states Expressed in our new terms we find again the patient proposing something to his analyst and the analyst responding to it according to his own apostolic function Compared with the general practitioner we analysts are in a better position because we possess a considerable literature which advises us in some detail which parts and aspects of the material produced by our patient should be interpreted when and how Despite this important difference the apostolic function operates automatically—exactly as in the case of the general practitioner The illness as it develops and changes in the two person analytic situation is always the result of a compromise, of an interaction between the analyst and his patient

To show what I mean by this interaction I wish to quote a historical example

In Freud's early writings the illnesses most frequently mentioned were hysteria, phobia, and the group he called actual neuroses foremost amongst them neurasthenia. It was he who detached from that group the obsessions, and in the next period these seem to have dominated the field. In still later years actual neuroses practically disappeared from the literature and almost every case was described either as character neurosis or neurotic character disorder Nowadays we have learnt to recognise the importance of depressive paranoid and other psychotic mechanisms in nearly all our cases

Does this mean that the patient material itself has changed ? In my opinion it means rather that our knowledge of the human mind has changed, has deepened

6244

and widened, and that consequently our responses to the patient's propositions and offers are different now from what they were fifty, thirty, or even twenty years ago A consequence, and a very important one, of this change in our responses, in our apostolic function, is that by them we determine, so to speak, the main spheres of the mind, where the most important parts of the analytic work have to be done This may explain why analyses today are so different from what they used to be

I have discussed the need for the general practitioner to respond to his patient's propositions in such a way that the ensuing compromise should focus attention and interest on the proposition which offers the best prospect of therapeutic help But there is equal need for us psycho-analysts to ask ourselves whether our present responses to our patients' propositions—i e our present ways of interpreting the material produced by the patient—lead to a compromise which focuses attention, interest, and libido on the proposition which offers the best prospect of therapeutic help

I know that these ideas throw a heavy and alarming responsibility on all of us—general practitioners, specialists, psycho-analysts alike—but I cannot see how any one of us can avoid shouldering it And I firmly believe that by becoming more and more aware of our roles in the patient-doctor relationship—i e , of our side effects as drugs—our therapeutic efficiency will grow apace

POSTSCRIPT

Throughout this address I have used the word "illness" in the same sense as it is used in general medicine For example, in the first case discussed, the four conditions were described as illnesses in their own right, although obviously they may influence one another or one may be secondary to the other

If I am right, psycho-analysis is about to develop a new conception, which may be called "basic illness" or perhaps "basic fault" in the biological structure of the individual, involving in varying degrees both his mind and his body The origin of this basic fault may be traced back to a discrepancy in the early formative years (or possibly months) of the individual between his own needs and the care and nursing available at the relevant times This creates a state of deficiency whose consequences are only partly reversible Although the individual may achieve a good, or even very good, *adjustment* the vestiges of his early experiences remain and contribute to what is called his constitution his individuality, or his character make-up both in the psychological and the biological sense The cause of this early discrepancy may be congenital—i e , the infant's needs may be too exacting—or may be environmental, such as insufficient careless, haphazard, over-anxious, over protecting, or only un-understanding care

Should this theoretical approach prove correct, then all the pathological states of later years the "clinical illnesses," must be considered as symptoms or exacerbations of the "basic illness," brought about by the various crises in the development external and internal, psychological or biological of the individual I wish to explain that my address was concerned only with the "clinical illnesses" of later years and not at all with the "basic illness"

---

how far can the general practitioner be rigidly scientific and if he could and did would he not become the 'medical technician' of whom some doctors disapprove? Who would then deal with the patients disabilities, inabilities, disorders, as distinct from narrowly defined 'diseases'? And would the patient, *qua* patient, be allowed to be neurotic, or ever normally worried or subject to conflicts? Would the average doctor be happy if his 'non scientific' problems were handed over entirely to almoners, social workers, psychiatric social workers, marriage guidance counsellors, family welfare advisers poor man's lawyers and specially selected priests? Most of these perform their functions excellently when properly chosen and trained but would the increase in their responsibilities and numbers decrease those of the doctors as we understand the term?"—T H PEAR *So[illegible] in English Life* London, 1955, p 39

BILATERAL LUMBAR PLEXUS LESIONS SIMULATING CAUDA-EQUINA COMPRESSION

ALEXANDER R TAYLOR

INFLAMMATORY disease of vertebral bodies, commonl tuberculous, often proceeds to collapse and compre of the posteriorly lying neural structures in the spin canal Paraparesis or paraplegia results Less ofte disease extending laterally into one or both psoas muscl compartments causes paraplegia or paraparesis by involving the outflowing nerves of the lumbar plexus Fe such cases, are considered here, and attention is draw to the features differentiating bilateral plexus lesions fro the more common cord or cauda equina compressions.

Study of the literature indicates that even unilater lumbar plexus lesions are uncommon in associat with psoas abscess

Case-reports

Case 1—A boiler fireman, aged 56, was admitted hospital on April 11, 1946, complaining of a dull ache in th left sacro iliac region for one year The pain was aggravat by bending forward and relieved by rest Latterly it h radiated down the posterolateral aspect of the left thigh calf to the lateral malleolus and had been accompanied stiffness in the lower back

Examination showed evidence of hypertension and arterio sclerosis The spine had a slight tilt to the right with marked restriction of mobility There was tenderness on pressure over the spines of the third, fourth, and fifth lumbar vertebræ, with reference of pain to the left buttock Motor power was deficient in the left glutei, hamstrings, posterior calf muscles and peronei On the right side there was weakness of the dorsi and plantar flexors of the ankle and of the peronei The left knee jerk was greatly depressed and the ankle jerk less so The right tendon jerks were normal There was sensory loss in either leg Straight-leg raising was limited on the left side to 60° with reference of pain to the left hip

Investigations—Lumbar puncture produced clear fluid under a pressure of 150 mm. There had be unsuccessful punctures elsewhere, and the yell thought to be explained by previous trauma Quec test was negative There was no increase in white and the total protein was 80 mg per 100 ml The W reaction was negative for both blood and cerebrospinal (c s f) Radiography showed partial collapse of the body the fourth lumbar vertebra with considerable narrowing of disc space between the third and fourth lumbar No paraspinal abscess shadow was seen Pronounced arthritic changes *suggested that the condition* was of standing The provisional diagnosis was "com of the fourth lumbar body with a lesion of the third fourth intervertebral disc causing bilateral compression"

Progress—Arrangements were made for spinal dec sion of the affected roots, biopsy, and subsequent fusion The patient was later admitted to hospital for purpose, but by then his symptoms had subsided to extent that he wished to return to work There was weakness of the leg muscles Spinal movements had Tendon reflexes were still depressed in the left leg The pressure was now 100 mm , with normal dynamics. fluid contained 18 white cells per c.mm. Protein was per 100 ml

Age, hypertension, and symptomatic improvement together decided in favour of conservative treatment returned home and resumed work Five months later been well in the interval, he was admitted to a medic with hæmatemesis and melæna, and complaining of frontal headache and cough Signs of meningitis afterwards Intracranial pressure increased progressively l the cells in his c.s.f He lapsed quickly into coma and ten days after admission.

cropsy showed in addition to the tuberculous meningitis n caused death a spinal lesion from which it took its n The fourth and fifth lumbar vertebræ were extensively d and replaced—mostly anteriorly—by soft caseous rial. From this lesion pus extended laterally into the tance of the psoas muscles on either side The lumbar es were not examined microscopically There was no dural extension of the disease The spinal cord and showed congestion of the pia mater but no surrounding late

ase 2 —A ploughman aged 28 a diabetic under treat t had a Brodie s abscess of the left femur drained on 17 1945 Four months later it had healed On Nov 20 he complained of low backache and pain radiating into sacrum. Next day it spread to both groins. The front e left thigh felt numb Two weeks later he was admitted to rgical ward with increased pain and a swinging tempera Large doses of penicillin did not control the infection. r days later he had difficulty in initiating micturition, and eloped severe abdominal distension He complained of kness of the thigh muscles and numbness of the front of h thighs.

xamination and Investigations—He preferred to lie on back with both hips flexed. Distension was too great to mit of successful abdominal palpation There was no spinal ormity and only slight tenderness on pressure or percussion r the mid lumbar spine In the lower limbs there was sting and bilateral flaccidity of the quadriceps muscles, h lesser wasting of the adductors of the thigh The anterior al group were still less weakened. Other muscle groups wed normal power. The knee-jerks were both absent and ankle-jerks preserved Plantar responses were flexor ere was bilateral depression to all modalities of stimuli r an area in the legs corresponding to the first second and rd lumbar dermatomes on the right and to the first second, rd and fourth lumbar dermatomes on the left Above d below this level sensation was normal Joint position se was unimpaired. Skiagrams of the lumbar and thoracic ines were normal The white-cell count was 20 000 per nm.—mostly polymorphs. Blood-culture was sterile tradural spinal abscess was diagnosed

Management and Progress—The extradural space was plored by excision of the ligamentum flavum bilaterally tween the eleventh thoracic and first lumbar levels. Condi ons there were found to be normal with fat of the usual nsistency and a normally pulsating dura. A fine rubber theter passed freely upwards and downwards for 5 cm. in e epidural space Exploration was also carried out between e third and fourth lumbar levels with negative results. umbar puncture at the close of the operation showed that ere was free conduction of fluid throughout the spinal eca. There was no increase of cells in the fluid and the otein content was 20 mg per 100 ml Attention was then cused on the affected nerves in their extraspinal course xploratory puncture revealed chocolate-coloured pus anterior o the lumbodorsal fascia in both loins. *Staphylococcus ureus* insensitive to penicillin was cultured Paralytic eus developed and the patient died two days later

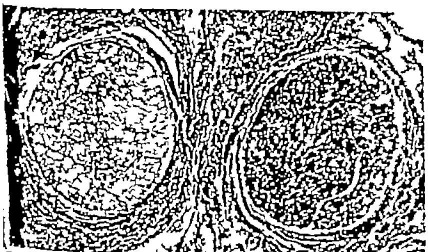

Fig 1—Section of the nerve trunks in case 2, showing inflammatory changes in the perineurium and patchy demyelination in one bundle (Anderson s stain, × 40)

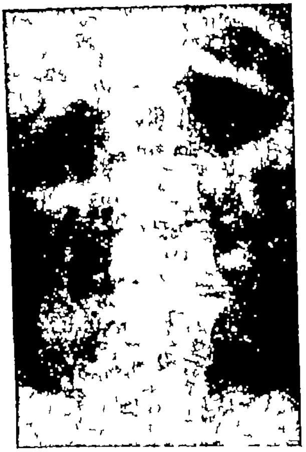

Fig. 2—Radiograph of the lumbar spine in case 3 showing the lesion in the bodies of the third and fourth lumbar vertebræ and calcification in a right-sided psoas abscess.

At necropsy in addition to the old abscess in the femur an area of eroded infected bone was found on the medial surface of the left ilium It formed a small part of the wall of massive abscess cavities in the sub stance of both psoas muscles the cavi ties communicated across the lower lumbar vertebræ and extended from the suprarenal glands to the pelvic brim The fifth lumbar body was destroyed anteriorly to a depth of 5 mm. and the fourth was affected to a lesser extent The abscesses contained pale chocolate-like fluid The sheaths of the lumbar nerves lying in the abscess cavities were swollen and congested. The autonomic nerves also lay in the abscess wall The spinal cord showed no abnormality Sections of the nerve trunks showed the epineurium to be involved in a subacute inflammatory process (fig 1) There was patchy demyelination and œdema around the fibres. The histological diagnosis was " pyogenic interstitial neuritis.

Case 3 —A housewife aged 26 suffered from bilateral pulmonary tuberculosis which was diagnosed in March 1946 In November, 1946 while under sanatorium treatment she began to complain of pain in the lower lumbar region radiating to the front of the right thigh.

Examination and Investigations—A psoas abscess was palpable in the right iliac fossa. There was spasm of the lumbar muscles and a lumbar kyphosis but no abnormal neurological signs in the lower limbs. Radiography showed erosion of the contiguous bony borders of the third and fourth lumbar bodies and narrowing of the intervertebral space (fig 2) The outline of the right psoas shadow was ragged the left was normal. Lumbar puncture produced clear c.s.f under normal pressure Queckenstedt s test was negative There were 2 cells per c.mm and 50 mg of protein per 100 ml This was taken to exclude intraspinal disease or at least to rule out the possibility of cord or cauda compression.

Treatment and Progress—The patient was immobilised and the abscess emptied by aspiration on three occasions. Amounts of pus up to 150 ml were withdrawn in which tubercle bacilli were seen. By June 1947 there was less spasm of the lumbar muscles and lumbar tenderness was not so severe, but considerable weakness of the right quadriceps muscles had developed and both knee-jerks were absent. There was no apparent motor weakness on the left side and no sensory loss in either leg An attempt to aspirate the abscess at this time was unproductive. A month later the patient complained of weakness of the left leg Examination then revealed loss of power in both quadriceps muscles, and some weakness in the hamstrings and the dorsiflexors of the ankles and toes. The weakness was greater on the right side There was sensory loss to all modes of stimulus over the third fourth, and fifth lumbar dermatomes on both legs The sacral segments were normal. Knee jerks were absent and ankle-jerks present The right psoas abscess was emptied again but an attempt to aspirate pus from the left psoas compartment failed Radiography showed little alteration in the vertebral disease but now there was evidence of disease in the left psoas muscle as well as in the right though no mass could be palpated on the left side

Further Progress—After aspiration of the right psoas abscess there was improvement in both legs. Power recovered in the right quadriceps first, and thereafter the right knee jerk returned A month later the left knee jerk had returned and no sensory abnormalities were demonstrable on either side More pus was aspirated from the right side on two occasions Further left sided aspirations yielded no pus, but a mass became palpable in the left flank Over the next six months progressively smaller amounts were removed from the right abscess and some calcification of its outline appeared in skiagrams Eventually there was no demonstrable neurological abnormality in the legs and this state of affairs has been maintained

Case 4 —A colliery washerman, aged 40, had suffered from tuberculous disease of the spine since childhood When first seen as an outpatient on Nov 5 1947, he complained of weakness of the ankles for one year and had adopted a high stepping gait to overcome this For two months he had experienced pain radiating down the posterolateral aspect of both buttocks thighs, and calves, and extending across the dorsum of the feet into the big toes Weakness spread to involve the knees and his gait became quite unsteady He was known to have had a right psoas abscess at the age of 8

On examination there was a gross kyphosis with its apex at the lower thoracic level No abdominal mass was palpable The left leg showed weakness of the external rotators of the hip and the hamstrings, with complete paralysis of the dorsiflexors and evertors of the ankle and weakness of the invertors On the right side there was a lesser weakness of the abductors and external rotators of the hip, of the hamstrings, and of all the muscles moving the ankle except the plantar flexors The knee jerks were depressed The ankle jerks were brisk and equal and the plantar responses flexor The abdominal reflexes were symmetrical but sluggish There was sensory depression to all types of stimuli in the fifth lumbar and first sacral dermatomes bilaterally The sensory loss was thus much less extensive than the motor

Investigations —Radiography showed lumbodorsal kyphosis with an angulation less than 90° The twelfth thoracic and first and second lumbar bodies were disintegrated and the upper half of the third lumbar body eroded—apparently recently The calcified lower end of a psoas abscess was seen on the right side

Progress —It was suggested that the referring surgeon should carry out a lumbar puncture to make sure that there was no spinal fluid obstruction and then empty the supposed psoas abscess by aspiration or operation Before this could be done the disease process extended Difficulty in micturition developed and with it anæsthesia in all sacral segments He was admitted to the neurosurgical unit with a complete paraplegia

Operation —Immediate decompression was carried out through an anterolateral approach Sequestrated disc and necrotic bone was removed from in front of the dura and an abscess evacuated from the right paraspinal region

Further Progress —After operation he required continuous bladder irrigation for fourteen days after which he passed urine normally Sensation in the sacral segments returned but depression persisted in the fifth lumbar and first sacral dermatomes bilaterally For some time there was spasticity in both legs but this disappeared in two months and the plantar responses became flexor again

Follow up examination nine months later revealed some weakness of the dorsiflexors and evertors of the right ankle and of the dorsiflexors of the toes There had been some return of power to the dorsiflexors of the left ankle but ankle evertors and the dorsiflexors of the toes remained paralysed The right knee jerk was weakly present the left absent Both ankle jerks were brisk and equal Plantar responses were flexor Bowel and bladder function was normal The weight was increasing and the erythrocyte sedimentation rate was normal All signs of cord compression had apparently disappeared and there was a return to the initial state showing bilateral involvement of the nerves of the lumbar plexus

This case is included with less confidence because the absence of C S F obstruction was not demonstrated initially Further involvement of the lower plexus roots is unusual and the lesion could possibly have been caused by epidural granulation tissue surrounding the lower [illegible]r roots intraspinally

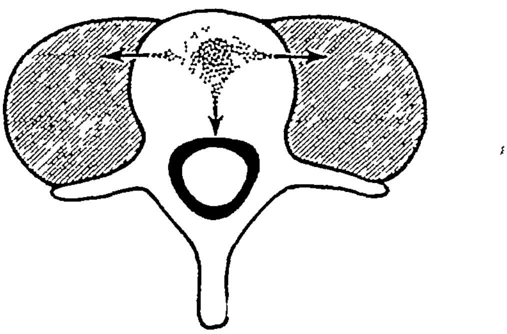

Fig 3—Diagram showing the relationship of a vertebral disease-focus to the spinal canal behind and to the psoas compartments on either side

Discussion

MECHANISM OF NEURAL INVOLVEMENT

Vertebral disease may spread in two directions to involve nerves—laterally into the substance of the psoas muscle or posteriorly to compress the spinal cord or cauda equina (fig 3) In assessing the probabilities reflected in bilateral neurological deficits in the lower limbs it must be remembered that a tuberculous focus in a body may spread into both adjacent psoas muscles without at the same time passing backwards This happened in the first three cases, but in the fourth bilateral spread occurred first and later was followed by posterior compression

DIFFERENTIAL DIAGNOSIS

Diagnosis should not be difficult on clinical grounds, provided the possibility of bilateral plexus lesions is remembered In cauda equina compression there will probably be bilateral symmetry and some involvement of the sacral roots Bladder dysfunction is almost invariable In plexus lesions neural involvement is usually asymmetrical and the sacral roots escape Bladder function is normal Case 2 complained of difficulty in starting micturition, but this was probably caused by involvement of the sympathetic nerves on the posterior pelvic wall Radiography *may show* the presence of psoas abscesses Lumbar puncture with Queckenstedt's test shows free C S F conduction if the lesion is extraspinal It should not be necessary to resort to myelography

Intrinsic spinal cord lesions should not be difficu to differentiate A glioma or angioma at the level of t second to fourth lumbar segments can cause lower mot neurone lesions like those of lumbar plexitis, and m even cause spinothalamic sensory defects with spari of the sacral dermatomes, but there will also be prese signs of pyramidal tract interruption causing increa of the ankle jerks and extensor plantar responses

Though all our cases had chronic infective lesio it is possible to imagine neoplastic conditions causi bilateral plexus involvement without intraspin extension

We have had under observation for four years a patient wi a myeloma of the tenth thoracic vertebra which had collapse She had a mixture of signs of spinal cord compression a lumbar plexus involvement When the spinal cord had be decompressed and the whole diseased area treated by radi therapy the sensory level of analgesia disappeared a bladder control was restored There remained lower mot neurone lesions causing flaccid paralysis below the knee which were almost certainly caused by infiltration or co pression of the lumbar plexus in its extraspinal course

NATURE OF THE PLEXUS LESION

In the only one of the four cases in which histologic material was available the nerve lesion was described a pyogenic interstitial neuritis. The epineurium was involved in a subacute inflammatory process and the fibre bundles showed œdema and patchy demyelination. This may be the common lesion.

Tallroth (1939) records a case of iliopsoas hæmorrhage in a hæmophiliac which was followed ten days later by signs of a femoral nerve lesion. He found no previous record of a similar case associated with hæmophilia. He points out that of the nerves in the psoas compartment the genito femoral obturator, and lateral cutaneous nerves are thinner and run more transversely and over shorter distances, than does the femoral which lies within the sheath all the way from its origin to the pelvic brim. The femoral nerve is therefore more vulnerable than the others. He suggests that the nerve lesion was caused by rapidly increasing pressure associated with an oozing hæmorrhage. In support of the pressure hypothesis he says that gravitational abscesses from tuberculous spondylitis do not cause femoral nerve lesions because the pressure rises slowly.

Michelson (1945) describes a case of trauma to the psoas muscle with hæmorrhage within the sheath and temporary impairment of sensation in the territory of the ilio inguinal nerve. Considering the cause of the nerve lesion he says

> Sudden increase of pressure within the psoas sheath due to hæmorrhage and/or infection may irritate the enveloped nerves sufficiently to produce symptoms of neuritis. Nerves are not involved with chronic slowly progressive lesions such as arthritis of the spine due to tuberculosis.

In Vuori's (1947) review of the condition of primary suppurative myositis in the psoas muscle there are no cases of neural involvement.

Schroeder (1938) describes five cases of primary psoitis none of which showed evidence of neuritis. This condition of primary psoas abscess usually staphylococcal in origin is the one in which neuritis would be expected whether the cause is increased pressure or inflammation.

Increased pressure within the psoas compartment bounded by an unyielding fibrous sheath appears to be a factor common to all the cases described. The four reported here make it clear that the increase of pressure does not require to be rapid as Tallroth (1939) and Michelson (1945) suggest. The histological finding of inflammatory changes in the lumbar plexus in case 2 does not necessarily mean that they had a causal significance in the production of neurological dysfunction. The absence of neurological signs in reported cases of acute suppuration in the psoas muscle indicates that toxic inflammatory changes in the nerve sheaths are unlikely by themselves to interfere with neural conduction.

We suggest that compression of the vasa nervorum of the lumbar plexus is the primary reason for the nerve changes. This should be relieved by closed or open drainage of the psoas compartment.

Summary

Bilateral neurological abnormalities in the distribution of the lumbar nerves may be caused by two paraspinal lesions as well as by one intraspinal lesion though the two will probably arise from one vertebral focus.

Four such cases are reported and the differential diagnosis and treatment discussed.

The cause of the plexus lesion is probably simple increase of pressure within the psoas compartment, and treatment should be directed towards lowering this pressure.

HEIGHT, WEIGHT, AND SKELETAL MATURITY IN THE FIRST FIVE YEARS OF LIFE

ROY M ACHESON

DAVID HEWITT, M.A

From the Social Medicine Unit Oxford University

SEVERAL communications from the Oxford Child Health Survey (see bibliography) have referred to the height, weight, and skeletal maturity status of the children but these measurements have not hitherto been reported in full. Compared with other ages there are very few height and weight tables for preschool children. It is also alleged that there is a secular change in the size of children of given age (Clements 1953). Measurements of skeletal maturity status are extremely rare, and the present assessments are not only the first to be based on British children, but also the largest series to be published anywhere.

The aims of the Oxford Child Health Survey were described by Ryle (1948) and full details of recruitment and conduct have since been published. The original group of Survey children were born (in Oxford) between 1944 and 1948 and some younger brothers and sisters have since been added to the series. All the children were examined at the age of 6 months and thereafter at six monthly intervals until they reached the age of 5. If, as a result of a mother altering the date of a clinical appointment any weight or height was recorded as long as a fortnight before or a fortnight after the correct date it has been excluded from the following tables. X ray findings were excluded if they were taken more than a month before or after the correct date. The vast majority of records were taken on the day the child reached the stated age.

Height (table I)

Height was measured with the child standing barefoot. A few babies could stand at the age of 12 months; but it was not until they were 18 months that as many as half the children were able to coöperate and not until 2 years that all the children could be measured.

TABLE I—STANDING HEIGHT (IN INCHES) OF OXFORD CHILD HEALTH SURVEY CHILDREN FROM 18 MONTHS TO 5 YEARS

Age (years)	Boys			Girls		
	No	Mean	S.D	No	Mean	S D
1½	134	31·86	1·30	120	31·09	1·20
2	251	33·05	1·39	202	33·19	1·27
2½	210	35·02	1·44	259	35·08	1·45
3	24[illegible]	37·28	1·60	263	36·71	1·46
3½	239	38·84	1·69	246	38·34	1·43
4	243	40·16	1·74	260	39·70	1·53
4½	224	41·62	1·79	238	41·01	1·60
5	234	42·75	1·00	238	42·38	1·72

Weight (table II)

When small the children were weighed naked and at later ages they wore only a single layer of underclothes.

Skeletal Maturity Status (tables III and IV)

Skeletal maturity was assessed in two ways. The first method was to compare the X ray films of the hands with the standard hand films for stated ages published in Todd's atlas (1937) This method, by giving "skeletal age" to the nearest six months (three months for the youngest children), yielded a rather coarse grouping from which it was not possible to calculate valid standard deviations However, the mean values shown in table III are probably satisfactory The second method of assessing maturity status, which is described in detail elsewhere (Acheson 1954b), dispenses with the concept of skeletal age and, in the form of "Oxford maturity units," provides skeletal maturation with its own yardstick This method yielded a relatively fine classification for the two hand films from which standard deviations, as well as means, could be calculated (table III) The same method was applied to both knees but in this case the frequency distributions were so irregular that they could only be characterised in terms of the mean and certain arbitrarily chosen percentile points (table IV)

DISCUSSION

In this country recent height and weight tables for the preschool child have been published by Gore and Palmer (1949) and by Low (1952) Neither of these sets of data are strictly comparable with ours Low's figures are based on a longitudinal study of 60 boys and 60 girls born in Aberdeen nearly thirty years ago These children were at all ages shorter and lighter than the Oxford children Gore and Palmer's study is also on a much smaller scale than the Oxford Survey, and is based on measurements taken in a single year, 1947 Every age-group consists of a separate sample of children, and within each one there are differences of weeks or months between the ages of the individual children These facts, preclude any exact comparison between their London children and the present series

TABLE II—WEIGHT (IN POUNDS) OF CHILDREN FROM BIRTH TO 5 YEARS

Age (years)	Boys			Girls		
	No	Mean	S D	No	Mean	S D
Birth	298	7 63	1 08	282	7 31	1 06
½	239	17 51	2 19	316	16 11	2 16
1	280	22 68	2 55	269	21 08	2 87
1½	299	25 44	2 93	285	23 90	2 99
2	290	27 76	3 23	289	26 14	3 40
2½	251	29 80	3 55	261	28 62	3 55
3	245	32 21	4 12	264	31 02	4 13
3½	211	34 60	4 67	246	33 21	4 28
4	213	36 75	4 90	250	35 60	5 04
4½	225	38 94	5 12	237	37 68	6 24
5	235	41 01	5 85	235	39 78	5 71

It will be noticed that the mean skeletal ages in table III are in every case less than the corresponding calendar ages That is to say, the Oxford children were behind the schedule of maturation drawn up by Todd for American children The mean skeletal age for g appears to overtake and pass that for boys, b it is thought that this results from an error the Todd standards for girls (Acheson and Hew 1954b)

Shuttleworth (1937) has emphasised that the ch value of longitudinal growth surveys is that th permit an accurate study of increments The Oxfo material is being examined from this point of vie and some of the findings have already been publishe At present a detailed study is being made of the effe of illness and adverse social circumstance on growth a skeletal development which, it is hoped, will throw furth light upon the process of maturation, and make possible to improve upon existing radiological metho of estimating maturity status

The Oxford Child Health Survey began in 1944 and r for ten years It was initiated by the late Prof John Ry and supervised at first by him and later by Dr Alice Stewa Dr Cicely Williams and Dr Celia Westropp bore the bru of the clinical and somatometric work, and Miss Elinor Robe and Miss Margaret Barnes shared the task of X raying t children From 1944 to 1950 the Survey was financed sole by the Nuffield Provincial Hospitals Trust, but from 19 onwards the Medical Research Council contributed generous towards its expenses

It is now generally agreed that the fall in blood pressure during fainting results from peripheral vasodilatation rather than from any failure of cardiac function During venesection cardiac output decreases, but if a faint ensues output does not decrease further (Barcroft et al 1944) Lewis (1932) found that atropine abolished the bradycardia during fainting but had little effect on the hypotension or level of consciousness, and to emphasise the combined vagal and peripheral effects in these disturbances he used the term "vasovagal" attacks.

John Hunter (1793) observed that venous blood from the arm became bright scarlet during fainting McDowall (1938) ascribed pallor of the face to general cutaneous vasoconstriction and concluded that the explanation of Hunter's finding was vasodilatation in the muscles This hypothesis was seemingly confirmed by reports of vasodilatation in the forearm during posthæmorrhagic fainting (Barcroft et al 1944 Barcroft and Edholm 1945) and emotional fainting (Greenfield 1951) However measurements of skin blood flow during fainting have not agreed with each other (Weiss et al 1937, Barcroft and Edholm 1945, Rushmer 1944 Hertzmann 1954)

We have witnessed nine fainting attacks, which were mostly emotional in origin Measurements of heat elimination from the hand showed cutaneous vasodilatation invariably accompanied fainting

Methods

Heat elimination from the hand was followed by means of the calorimeter described by Greenfield and Scarborough (1949) The subjects were seated with the arm dependent Calorimeter temperatures ranged from 28 to 33°C but in any one experiment did not vary by more than 1°C Room temperatures were between 21 and 24°C and remained within ± 0 5°C during any one experiment During seven faints sublingual and rectal temperatures were measured by copper constantan thermocouples (Cranston et al. 1954), and blood pressure was recorded by the auscultatory indirect method in five faints.

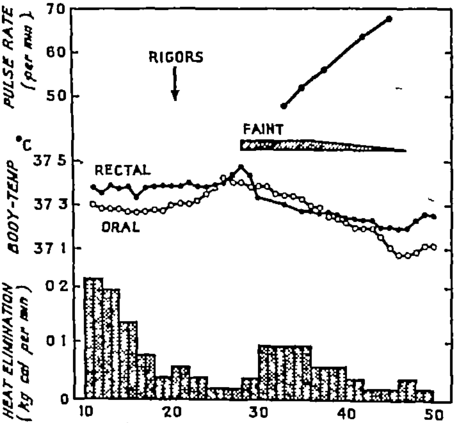

Fig 1—Pulse-rate, body-temperature, and heat elimination from hand in subject B.

In one healthy woman student (subject A) three faints were deliberately provoked by puncturing an arm vein with a sharp needle and withdrawing 5 ml. of blood she was seated on a high stool and the procedure was virtually painless The remaining six faints occurred in five men incidentally after the intravenous injection of bacterial pyrogens, which had been incubated in the subject's own blood (Gerbrandy et al. 1954a) (The pyrogens were injected therapeutically in three men with eczema and experimentally in two of ourselves) The volumes of blood injected were 10–50 ml. in four experiments and 200 ml. in two Four of the faints took place within ten minutes of the injection and at least forty five minutes before the onset of fever: the other two occurred twenty-eight and thirty five minutes after injection, during the onset of fever

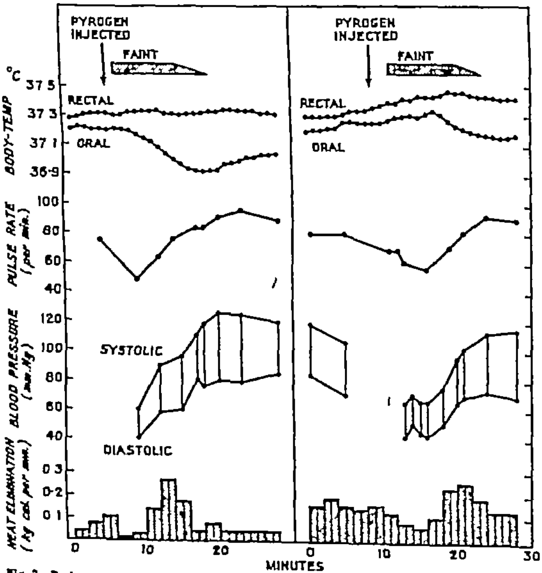

Fig. 2—Body-temperature, blood-pressure, pulse-rate and heat elimination in subject C.

Results

In none of the nine faints observed was there complete loss of consciousness. The first four faints observed were unexpected in all of them the pulse slowed and became irregular, but blood pressure was not recorded Heat elimination increased in all, including two subjects who were developing a fever with rigors and powerful vasoconstriction The observed changes in subject (B) are shown in fig 1, the abscissa of which represents the time after the injection of 50 million *Escherichia coli* in 16 ml of blood The ensuing fever was associated with a fall of heat elimination to very low levels rigors, and a small rise in mouth and rectal temperatures At this time he fainted the pulse rate was then 48 per min , and heat elimination increased to 0 09 calories per kg per min At the same time there was a fall in oral and rectal temperatures During recovery from the faint, heat elimination decreased and the pulse rate rose

---

* In receipt of a grant from the Holland Scholarship Trust on the recommendation of the Netherlands Organisation for Pure Research (Z.W O)

Subject C fainted on two separate occasions, after the injection of 50 million *Esch coli* in 30 ml of blood, and the results are shown in fig 2 Both faints took place at least forty five minutes before fever began During each attack there was a small transient decrease in heat elimination followed by a large rise , blood pressure, pulse-rate and oral temperature all decreased, while rectal temperature remained steady

The findings in the first experiment on subject A are shown in fig 3 First she witnessed a venesection on someone else about 50 ml of blood was run into a bottle and on to white towels This occasioned some emotional reaction but no fainting , the fall in heat elimination indicates cutaneous vasoconstriction, and there was a transient rise in systolic blood pressure 5 ml of blood was next withdrawn from a vein in the subject's own arm This provoked fainting, with weakness, clouding of consciousness, and pallor of the face, followed by sweating and hyperventilation The blood pressure fell by about 50 mm Hg and there was a small decrease in pulse rate and oral temperature Heat elimination rose from about 0 15 to 0 25 calories per kg per min

A further experiment on subject A is shown in fig 4 5 ml of blood was withdrawn from the subject, provoking a fairly severe and lengthy fainting reaction, with the same features as before Blood pressure fell to very low levels but there was only transient bradycardia Heat elimination rose to about three times its basal level, and stayed up until the blood pressure was increased by raising the legs The legs were again lowered, and this was followed by a milder faint with cutaneous vasodilatation during the period of hypotension

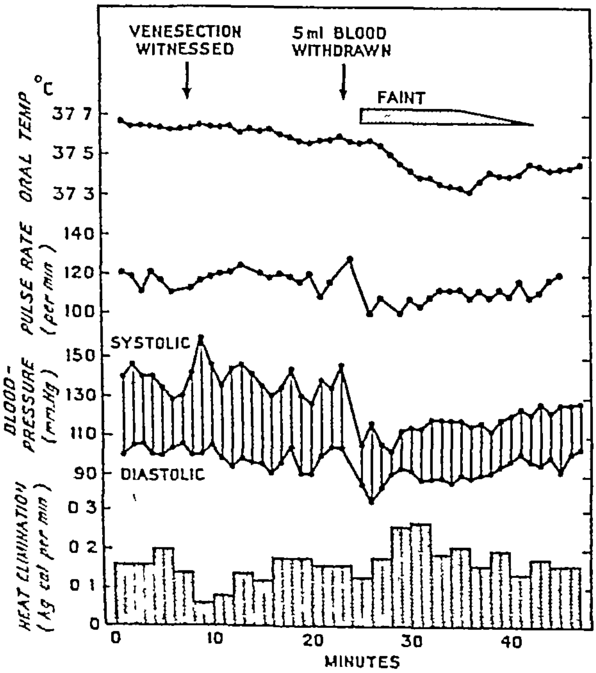

Fig 3—Oral temperature blood-pressure, pulse-rate and heat elimination in subject A.

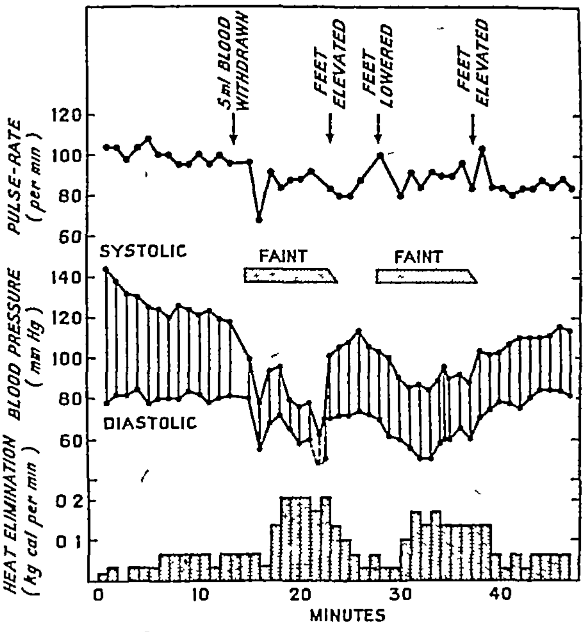

Fig 4—Observations on subject A

Discussion

The three faints observed in subject A were presumably almost entirely emotional in origin In the other subjects fainting occurred even if local anæsthesia had been given before the injection, so their responses cannot be entirely attributed to pain Fainting occurred in six out of forty six experiments in which pyrogen in blood was injected intravenously, and emotional factors are thought to have been mainly responsible for the attacks The general symptoms associated with the abrupt onset of fever may have played some part in precipitating the two faints twenty eight and thirty-five minutes after the injections

Normally there is loss of heat from the limb arteries to their *venæ comitantes* (Bazett et al 1948), and presumably also to other surrounding structures It is theoretically possible that the increase of heat elimination from the hand during fainting might be due to a rise in the temperature of the blood reaching the hand A slight rise in this temperature might result from vasodilatation in the forearm muscles, but this alone could not account for the observed increase in heat elimination It is much more likely that our findings indicate cutaneous vasodilatation in the hand during fainting This vasodilatation must be even grosser than the figures suggest, because it persisted in the presence of a lowered blood pressure Vasodilatation occurred even during periods of powerful cutaneous vasoconstriction, at the onset of fever It was not related to injection of pyrogen or blood, since similar increase in heat elimination was not observed in forty experiments of the same type in which fainting did not take place

There is a lag of at least one minute between the onset of vascular changes in the hand and any variations in recorded heat elimination, but otherwise calorimetry has fewer drawbacks than other methods as an index of skin blood flow during fainting The time relationships between changes in blood pressure and heat elimination (figs 1–4) suggest that skin vasodilatation contributes to the fall of blood pressure

Oral temperature invariably fell during fainting, but the extent of this fall does not necessarily reflect the effects of increased heat elimination on arterial blood temperature. We have previously observed during the onset of fever large falls in oral temperature with powerful cutaneous vasoconstriction (Cranston et al 1954); these changes were attributed to a reduction in the rate of blood flow through the mouth. The changes in oral temperature during fainting may be partly produced in the same way. Rectal temperature fell during one faint and was unchanged in the others, but it has been previously shown that rectal temperature responds poorly to changes in body heat (Gerbrandy et al 1954b). A decrease in cutaneous blood flow during fainting has been reported by Barcroft and Edholm (1945) and by Weiss et al (1937). Barcroft and Edholm induced fainting by reducing the circulating blood volume. Weiss et al used a combination of sodium nitrite and tilting. In both of these investigations blood flow was measured by a hand plethysmograph. During periods of hypotension the usual pressure in the collecting cuff may approach or exceed arterial pressure. Thus an artificially low blood flow may be recorded by this method. Barcroft and Edholm (1945) attempted to overcome this difficulty by decreasing the collecting pressure during the faint; the changes in blood flow which they depicted were inconstant, and were probably affected by the reduction of blood volume. In none of our experiments was reduction of blood volume induced by venesection or leg cuffs.

Rushmer (1944) followed the pulse volume in the finger during forty-five arterial punctures. Fifteen of his subjects fainted, though most of the punctures were painless and little blood was withdrawn. In all of these subjects pulse-volume increased during the faint. Hertzman (1954) recorded a similar observation in one case. This evidence is in favour of cutaneous vasodilatation during fainting.

The cutaneous vasodilatation during emotional fainting may affect forearm blood flow. Under resting conditions skin blood flow accounts for 0–67.5% of total forearm blood flow, and this proportion increases as skin flow increases (Cooper et al 1954). It therefore cannot be assumed that Greenfield's findings provide conclusive evidence for muscle vasodilatation during emotional fainting. Posthæmorrhagic fainting may be associated with different circulatory effects, and the increased forearm flow observed in this condition may be partly in the muscles.

Summary

Heat elimination from the hand has been measured during nine faints in six subjects. Six attacks followed intravenous injections of pyrogen in blood. Two occurred during the onset of fever, and the remainder were emotional in origin.

During all the faints cutaneous vasodilatation developed, judged by increased heat elimination from the hand.

Sublingual temperature fell during fainting, but with one exception rectal temperature remained constant.

Cutaneous vasodilatation contributes to the fall of blood pressure during emotional fainting.

We are indebted to Prof. G. W. Pickering and to Dr. G. Mitchell Heggs, physician in charge of the skin department, for permission to observe their patients who were undergoing fever therapy. We are also most grateful to subject A for her willing coöperation.

THAT psoriasis is particularly common in patients with rheumatoid arthritis has long been recognised, but a similar association between psoriasis and ankylosing spondylitis is not widely recorded. Cases of ankylosing spondylitis with psoriasis have—particularly in American accounts—been called "psoriasis arthropathica with sacro-iliac joint involvement." Coste and Forestier (1935) stated that it was rare to find ankylosing spondylitis complicated by psoriasis. Bouwens van der Boijens (1939) classified psoriasis arthropathica into eight types, one being the type associated with spondylitis; this he considered very rare. Epstein (1939) found 1 case of sacro-iliac joint involvement in 39 cases of psoriasis arthropathica. Of 150 cases of psoriasis arthropathica reported by Vilanova and Piñol (1951) 3 males had sacro-iliac joint involvement. They found that skin lesions were common over the trunk in spinal cases, and that these had a worse prognosis. Sherman (1952), reporting 15 cases of psoriasis arthropathica, noted 1 male who had had ankylosing spondylitis for forty years before the onset of psoriasis and peripheral joint involvement. Sterne and Schneider (1953), reporting 6 males with psoriasis arthropathica, mentioned 2 with sacro-iliac joint involvement; in both the peripheral joints were affected, but in only 1 did the skin lesion involve the trunk.

In 100 consecutive unselected cases of ankylosing spondylitis we found 4 with psoriasis. Since the incidence of psoriasis in the population is about 0.3% (Arnio and Clemmesen 1952) there would thus appear to be an association between ankylosing spondylitis and psoriasis comparable to that between *rheumatoid arthritis and* psoriasis. By analogy with psoriasis arthropathica this association may be called psoriasis spondylitica.

Case-reports

Case 1 was a woman, aged 39, who had developed psoriasis at the age of 11. When 25 years of age she complained of backache following the birth of her first child; this continued for fourteen years, becoming more severe with increasing limitation of spinal movement; latterly her right hip and shoulder had become painful. 3 brothers and 1 uncle had ankylosing spondylitis.

On examination her chest expansion was normal. There was a dorsal kyphosis, lumbar lordosis, and *limitation of* movement of the lumbar spine; she was unable to reach within 4 in. of her toes. There were plaques of psoriasis on both knees. The erythrocyte-sedimentation rate (E.S.R.) was 31 mm. in the first hour (Westergren). Radiography revealed squaring of the mid-dorsal vertebræ and irregularity and sclerosis of the sacro-iliac joints.

Case 2 was a man, aged 37, who worked as a post office clerk At 17 he had developed psoriasis 4 years later he complained of pain in both buttocks, localised to the ischial tuberosities and radiating down the backs of both thighs At the age of 23 he entered the Army and was placed in grade I, but a year later he again developed pains in the buttocks, these pains became severe and he was transferred to grade III A few months later he was referred to a psychiatrist and was discharged from the Army with "rheumatism and nerves" When he was 24 he began to have pain between the shoulder blades which was diagnosed as fibrositis and treated with infra red radiation and massage The pain in the buttocks and shoulder blades continued until the age of 29, when he developed pain and stiffness in the lower part of his spine, this was diagnosed as lumbago and treated with radiant heat The pain persisted until the age of 32, when ankylosing spondylitis was diagnosed He was treated with deep X rays with relief of symptoms His paternal grandfather, father, mother and a brother have psoriasis

On examination his chest expansion was 2 in, the spine was stiff, and he was not able to reach within 12 in. of his toes There was an upper dorsal kyphoscoliosis with obliteration of lumbar lordosis There were small patches of psoriasis on both elbows and knees The E.S.R. was 22 mm in the first hour (Westergren) Radiography revealed ankylosis of both sacro iliac joints and bambooing of the lower dorsal spine

Case 3 was a man aged 29, who at the age of 17 had developed psoriasis on the extensor surfaces of both forearms At 18 he entered the Army and was placed in grade I A year later he developed pain in his left hip, worse on sitting down, and at the age of 20 he was admitted to hospital with a diagnosis of tuberculosis of the left hip The following year the pain spread to his right hip and then to knees and elbows He was treated with gold injections but without improvement

At the age of 22 there was severe deterioration in his condition On examination at that time, the chest expansion was 1½ in, the skin was atrophic and there were plaques of psoriasis over the elbows and knees There was ulnar deviation of his hands, and his elbows were swollen, movements of the shoulders, hips and spine were severely limited The E.S.R. was 88 mm in the first hour (Westergren) Radiography of the pelvis showed obliteration of the sacro iliac joints The peripheral joints were treated with deep X rays but without improvement

At the age of 24 bilateral iritis developed and the patient became bedridden He was admitted to a chronic hospital where he now lies, aged 29, blind and completely helpless

Case 4 was a man aged 76, who had developed psoriasis at the age of 30 on both elbows and knees At the age of 64 he complained of stiffness of the neck and shoulders, low back pain and difficulty in walking He carried on work for four years until his hips became affected Radiographs at the age of 70 showed destruction of both sacro iliac joints and protrusio acetabuli of both hip joints He was treated with deep X rays with some improvement A maternal aunt had suffered from rheumatoid arthritis

On examination when he was aged 75 he appeared younger than his years There were patches of psoriasis on the left wrist and on the left buttock and natal cleft, and the movements of both wrists were limited The E.S.R. was 30 mm in the first hour (Westergren) At the age of 75 radiography of his hands showed destruction of the carpal joints, but the terminal interphalangeal joints were not affected

Discussion

Rheumatoid Arthritis and Psoriasis

The incidence of psoriasis in rheumatoid arthritis has been variously estimated at 2 6% (Dawson and Tyson 1938), 3 1% (Fletcher 1951), and 4% (Douthwaite 1935) Sherman (1952) stated that ulnar deviation is not seen in true psoriatic arthropathy and Epstein (1939) said that iritis is never found, but case 3, in which there was fulminating ankylosing spondylitis with peripheral joint involvement and psoriasis, showed both these complications

Rheumatoid Arthritis and Ankylosing Spondylitis

Because in some 25% of cases of ankylosing spondylitis the peripheral joints are involved, and the macroscopic and microscopic appearance of the joints is the same in rheumatoid arthritis as in ankylosing spondylitis, ankylosing spondylitis is sometimes thought to be nothing more than rheumatoid arthritis affecting the spine But for the following reasons the two conditions are considered, at least in Europe, to be distinct

(1) *Sex incidence* —Whereas rheumatoid arthritis is commoner in females (3 1), ankylosing spondylitis is commoner in males (6 1)

(2) *Age incidence* —Rheumatoid arthritis may appear at any age, whereas *ankylosing spondylitis most often starts in* the 15–40 age group

(3) *Course and prognosis* —Ankylosing spondylitis is more benign, most patients being able to continue at work Rheumatoid arthritis is characterised by more frequent remissions and relapses, 15% of patients becoming bedridden

(4) *Treatment* —Rheumatoid joints do not respond to deep X ray therapy, whereas the involved joints in ankylosing spondylitis do

(5) *Complications* —Necrobiotic nodules are hardly ever found in ankylosing spondylitis, but some 20% of patients with rheumatoid arthritis are so affected Moreover the incidence of iritis is greater in ankylosing spondylitis—15% in ankylosing spondylitis as against 5% in rheumatoid arthritis.

Ankylosing Spondylitis and Psoriasis

Arnso and Clemmesen (1952) found psoriasis in 2 of 20 cases of ankylosing spondylitis—an incidence of 10%, which is far higher than the incidence of 4% in our own series Psoriasis usually appears before rheumatoid arthritis in psoriasis arthropathica (Sterne and Schneider 1953), and in each of the 4 cases reported here the psoriasis developed before the onset of ankylosing spondylitis, the skin lesions were confined in all 4 cases to a few plaques over the knees and elbows Some cases of psoriasis arthropathica have a distinct clinical pattern with involvement of the terminal interphalageal joints, which is rarely seen in rheumatoid arthritis without psoriasis, but in the 4 cases of ankylosing spondylitis with psoriasis reported here the spondylitis was clinically indistinguishable from ankylosing spondylitis without psoriasis

Genetic influences play a part in the ætiology of both ankylosing spondylitis (Jacobs and Rose 1954) and psoriasis (Lerner 1940), as is shown by the family histories of cases 1 and 2 The former had 4 relatives (paternal uncle and 3 brothers) with ankylosing spondylitis, but none with psoriasis, and case 2 had 4 relatives (paternal grandfather, father, mother, and brother) with psoriasis, but none with ankylosing spondylitis

Ankylosing spondylitis often remains misdiagnosed for many years In view of this we suggest that if a pati with psoriasis complains of pain referable to the locomo system, the sacro iliac joints should be radiographed

Summary

4 cases of ankylosing spondylitis associated w psoriasis are reported

The relationship of ankylosing spondylitis, rheumat arthritis, and psoriasis to each other is discussed

UNIVERSITY OF MANCHESTER

Two foci of lymphocytic choriomeningitis (L.C.M.) infection in Manchester were described by Duncan et al (1951) and since then other cases have occurred in these two areas The case here reported in a newborn is the first recorded in infancy and evidence is presented that infection was acquired during the last stages of intra uterine life The mother was resident in one of the areas mentioned

Case history

A baby boy was born on June 4 1954 His mother had borne three other children who had been perfectly normal and thrived well. The mother was admitted to hospital on May 27 1954 eight days before delivery with four days history of malaise headache and vomiting On the day of admission she experienced some suprapubic pain and frequency of micturition there was no dysuria but very little urine was passed

On examination she had a cough and fever (temperature 103.8°F pulse rate 130) and there were generalised signs of bronchitis the blood pressure was 120/80 mm Hg and the fauces were mildly inflamed. Otherwise the examination was stated to be normal.

Investigations—Blood-cultures, radiography of the chest Widal and Paul Bunnell reactions, and repeated cultures of the urine had not elucidated the cause of the mother's condition by June 4. So the baby was immediately segregated at birth and not again brought into contact with the mother who continued to have a hectic swinging temperature and was transferred to another hospital, where on June 16 twelve days after the delivery the diagnosis of benign L.C.M. was suggested on the basis of a slight increase of cells and protein in the cerebrospinal fluid (C.S.F.) This was subsequently confirmed serologically the complement fixing antibody titre of her serum rising from less than 1/2 to 1/64

The infant weighed 6 lb 1 oz. at birth and appeared to be normal, passing urine and meconium on the first day He seemed to be well for the first six days because he fed satisfactorily and was active having a normal Moro and grasp reflex; but he lost 10 oz. in weight and by the eighth day 1½ oz. more. By this time his temperature had begun to rise and he was sucking indifferently and was a little dehydrated.

Investigations and Treatment—Aureomycin therapy (25 mg four hourly) was started A white-cell count of 31 900 per c.mm. (polymorphs 20% lymphocytes 52%) suggested an active infection, and streptomycin 125 mg daily was added to the therapy Tube feeding was started and subcutaneous saline solution was administered. The general condition remained stationary until June 15 when the infant's condition deteriorated and he had a convulsion Examination revealed some neck stiffness. Cisternal puncture produced clear xanthrochromic C.S.F. containing 4000 red cells and 54 white cells per c.mm. (36 polymorphs and 18 lymphocytes per c.mm.) and protein 150 mg per 100 ml. The possibility of virus meningitis or inclusion disease was considered at this stage

Course—There was rapid deterioration in the infant's condition and in six hours time the fontanelle was bulging and the baby showed severe opisthotonos. Cisternal and ventricular taps on this occasion revealed evenly bloodstained C.S.F. indicating subarachnoid hæmorrhage and the child died three hours later on June 16 1954 aged twelve days. A necropsy was done by one of us (B. L. W.) next day

Necropsy Findings—The body was that of a mature male infant weighing 4 lb 15 oz. and showing some wasting and dehydration Petechiæ were present on the lower abdominal wall groins and scrotum The *skull* was healthy with normal fontanelles. The *brain* weighed 300 g and appeared swollen There was extensive subarachnoid hæmorrhage over the left cerebral hemisphere and in the cisterna magna. On section the third and fourth ventricles and both lateral ventricles were moderately dilated and contained blood; the cut surface of the brain showed faint yellow discoloration Situated in the occipital lobe of the right cerebral hemisphere lateral to the posterior horn of the lateral ventricle was an area of intracerebral hæmorrhage 2 cm. in diameter and communicating with the lateral ventricle Macroscopic examination of the *thoracic* and *abdominal viscera* showed no abnormality

Microscopy—At the site of intracerebral hæmorrhage there was destruction of the brain tissue adjacent brain tissue showed œdema capillary congestion and sparse infiltration by macrophages. Overlying the left cerebral hemisphere and in the cisterna magna was hæmorrhage into the subarachnoid space Remote from the intracerebral and subarachnoid hæmorrhage the leptomeninges were congested and the subarachnoid space showed moderately severe lymphocytic infiltration There was also lymphocytic infiltration beneath the ependyma of the third and fourth and lateral ventricles Occasional blood vessels showed sparse perivascular lymphocytic cuffing Other tissues showed no significant abnormalities No obvious cause was found for the intracranial hæmorrhage which was thought to be due either to direct trauma (this seems unlikely in view of the situation) or more probably to change of intracranial pressure following the first cisternal puncture

Virological Investigations—A specimen of C.S.F. taken from the infant on June 15 1954 was inoculated intracerebrally into mice from a L.C.M. free stock and intraperitoneally into guineapigs. Eight days after inoculation the mice were sick with symptoms described by Traub (1936) as typical of L.C.M. A suspension of brain material from sick mice of this group was specifically neutralised by L.C.M. immune serum Complement fixing antigen prepared from the spleen of one of the two guineapigs killed on the sixth day after injection was also specific for L.C.M. The second guineapig bled from the heart fourteen days after inoculation showed L.C.M. complement fixing antibody in its serum. L.C.M. virus was also isolated from four pools of house mice caught in the mother's home

Discussion

Transplacental infection with L.C.M. virus has not hitherto been recorded although Traub (1939) and Haas (1941) have shown that it is the normal mechanism of infection in colonies of mice where the disease is enzootic.

In the present case since the infant was separated from the mother immediately after delivery no possibility of postnatal infection exists The possibility of paranatal infection must be borne in mind because it has often been stated that the urine in cases of human L.C.M. may contain the virus and thus the birth canal may have been contaminated Although it is well established that the virus is excreted in the urine of infected mice (Traub 1936) only one report has been published of the isolation of L.C.M. virus from the urine in man this is by Lépine and Sautter (1938) and appears to be of dubious validity

It therefore seems that transplacental infection was by far the most likely route in the present case particularly in view of the fact that the major phase of the mother's illness occurred at least a week before delivery In this connection it is of interest to mention that Swarts and Kercher (1954) have published a case of transplacental infection with poliomyelitis virus.

In further support of this view is the time of onset of the baby's illness. The incubation period of L.C.M. in man under natural conditions is extremely hard to establish because in most cases there is repeated exposure in the home environment van Rooyen and Rhodes (1948) give it as one to three weeks. In the two cases of laboratory infection reported by Milzer and Levinson (1942) and Lépine and Sautter (1938) the most likely times of infection were six and ten days respectively before the onset of disease though both cases were continuously exposed to the possibility of infection before these times In one of the cases of Smadel et al. (1942)

Case 2 was a man, aged 37, who worked as a post office clerk At 15 he had developed psoriasis 4 years later he complained of pain in both buttocks, localised to the ischial tuberosities and radiating down the backs of both thighs At the age of 23 he entered the Army and was placed in grade I, but a week later he again developed pains in the buttocks, these pains became severe and he was transferred to grade III A few months later he was referred to a psychiatrist and was discharged from the Army with "rheumatism and nerves" When he was 24 he began to have pain between the shoulder blades which was diagnosed as fibrositis and treated with infra red radiation and massage The pain in the buttocks and shoulder blades continued until the age of 29, when he developed pain and stiffness in the lower part of his spine, this was diagnosed as lumbago and treated with radiant heat The pain persisted until the age of 32, when ankylosing spondylitis was diagnosed He was treated with deep X rays with relief of symptoms His paternal grandfather, father, mother and a brother have psoriasis

On examination his chest expansion was 2 in, the spine was stiff, and he was not able to reach within 12 in of his toes There was an upper dorsal kyphoscoliosis with obliteration of lumbar lordosis There were small patches of psoriasis on both elbows and knees The E.S.R. was 22 mm in the first hour (Westergren) Radiography revealed ankylosis of both sacro iliac joints and bambooing of the lower dorsal spine

Case 3 was a man, aged 29, who at the age of 17 had developed psoriasis on the extensor surfaces of both forearms At 18 he entered the Army and was placed in grade I A year later he developed pain in his left hip, worse on sitting down, and at the age of 20 he was admitted to hospital with a diagnosis of tuberculosis of the left hip The following year the pain spread to his right hip, and then to knees and elbows He was treated with gold injections but without improvement

At the age of 22 there was severe deterioration in his condition On examination at that time, the chest expansion was $1^1/_2$ in, the skin was atrophic, and there were plaques of psoriasis over the elbows and knees There was ulnar deviation of his hands, and his elbows were swollen, movements of the shoulders hips, and spine were severely limited The E.S.R. was 88 mm in the first hour (Westergren) Radiography of the pelvis showed obliteration of the sacro iliac joints The peripheral joints were treated with deep X rays but without improvement

At the age of 24 bilateral iritis developed and the patient became bedridden He was admitted to a chronic hospital where he now lies, aged 29, blind and completely helpless

Case 4 was a man, aged 76, who had developed psoriasis at the age of 30 on both elbows and knees At the age of 64 he complained of stiffness of the neck and shoulders, low back pain, and difficulty in walking He carried on work for four years until his hips became affected Radiographs at the age of 70 showed destruction of both sacro iliac joints and protrusio acetabuli of both hip joints He was treated with deep X rays with some improvement A maternal aunt had suffered from rheumatoid arthritis

On examination when he was aged 75 he appeared younger than his years There were patches of psoriasis on the left wrist and on the left buttock and natal cleft, and the movements of both wrists were limited The E.S.R. was 30 mm in the first hour (Westergren) At the age of 75 radiography of his hands showed destruction of the carpal joints, but the terminal interphalangeal joints were not affected

Discussion

Rheumatoid Arthritis and Psoriasis

The incidence of psoriasis in rheumatoid arthritis has been variously estimated at 2 6% (Dawson and Tyson 1938), 3 1% (Fletcher 1951), and 4% (Douthwaite 1935) Sherman (1952) stated that ulnar deviation is not seen in true psoriatic arthropathy, and Epstein (1939) said that iritis is never found, but case 3, in which there was fulminating ankylosing spondylitis with peripheral joint involvement and psoriasis, showed both these complications

Rheumatoid Arthritis and Ankylosing Spondylitis

Because in some 25% of cases of ankylosing spondylitis the peripheral joints are involved, and the macroscopic and microscopic appearance of the joints is the same in rheumatoid arthritis as in ankylosing spondylitis, ankylosing spondylitis is sometimes thought to be nothing more than rheumatoid arthritis affecting the spine But for the following reasons the two conditions are considered, at least in Europe, to be distinct

(1) *Sex incidence*—Whereas rheumatoid arthritis is commoner in females (3 1), ankylosing spondylitis is commoner in males (6 1)

(2) *Age incidence*—Rheumatoid arthritis may appear at any age, whereas ankylosing spondylitis most often starts in the 15–40 age group

(3) *Course and prognosis*—Ankylosing spondylitis is more benign, most patients being able to continue at work Rheumatoid arthritis is characterised by more frequent remissions and relapses, 15% of patients becoming bedridden

(4) *Treatment*—Rheumatoid joints do not respond to deep X ray therapy, whereas the involved joints in ankylosing spondylitis do

(5) *Complications*—Necrobiotic nodules are hardly ever found in ankylosing spondylitis, but some 20% of patients with rheumatoid arthritis are so affected Moreover the incidence of iritis is greater in ankylosing spondylitis—15% in ankylosing spondylitis as against 5% in rheumatoid arthritis

Ankylosing Spondylitis and Psoriasis

Arnsø and Clemmesen (1952) found psoriasis in 2 of 20 cases of ankylosing spondylitis—an incidence of 10%, which is far higher than the incidence of 4% in our own series Psoriasis usually appears before rheumatoid arthritis in psoriasis arthropathica (Sterne and Schneider 1953), and in each of the 4 cases reported here the psoriasis developed before the onset of ankylosing spondylitis, the skin lesions were confined in all 4 cases to a few plaques over the knees and elbows Some cases of psoriasis arthropathica have a distinct clinical pattern with involvement of the terminal interphalageal joints, which is rarely seen in rheumatoid arthritis without psoriasis, but in the 4 cases of ankylosing spondylitis with psoriasis reported here the spondylitis was clinically indistinguishable from ankylosing spondylitis without psoriasis

Genetic influences play a part in the ætiology of both ankylosing spondylitis (Jacobs and Rose 1954) and psoriasis (Lerner 1940), as is shown by the family histories of cases 1 and 2 The former had 4 relatives (paternal uncle and 3 brothers) with ankylosing spondylitis, bu none with psoriasis, and case 2 had 4 relatives (patern grandfather, father, mother, and brother) with psoriasi but none with ankylosing spondylitis

Ankylosing spondylitis often remains misdiagnosed f many years In view of this we suggest that if a patie with psoriasis complains of pain referable to the locomot system, the sacro iliac joints should be radiographed

Summary

4 cases of ankylosing spondylitis associated wit psoriasis are reported

The relationship of ankylosing spondylitis, rheumato arthritis, and psoriasis to each other is discussed

UNIVERSITY OF MANCHESTER

Two foci of lymphocytic choriomeningitis (L.C.M.) infection in Manchester were described by Duncan et al. (1951) and since then other cases have occurred in these two areas The case here reported in a newborn is the first recorded in infancy and evidence is presented that infection was acquired during the last stages of intra uterine life The mother was resident in one of the areas mentioned

Case history

A baby boy was born on June 4 1954 His mother had borne three other children who had been perfectly normal and thrived well The mother was admitted to hospital on May 27 1954 eight days before delivery with four days history of malaise headache, and vomiting On the day of admission she experienced some suprapubic pain and frequency of micturition there was no dysuria, but very little urine was passed

On examination she had a cough and fever (temperature 103 8°F pulse-rate 130) and there were generalised signs of bronchitis the blood pressure was 120/80 mm. Hg and the fauces were mildly inflamed Otherwise the examination was stated to be normal.

Investigations.—Blood-cultures radiography of the chest Widal and Paul Bunnell reactions, and repeated cultures of the urine had not elucidated the cause of the mother s condition by June 4 So the baby was immediately segregated at birth and not again brought into contact with the mother who continued to have a hectic swinging temperature and was transferred to another hospital, where on June 16 twelve days after the delivery the diagnosis of benign L.C.M. was uggested on the basis of a slight increase of cells and protein the cerebrospinal fluid (C.S.F.) This was subsequently onfirmed serologically the complement-fixing antibody titre her serum rising from less than 1/2 to 1/64

The infant weighed 6 lb 1 oz. at birth and appeared to be ormal passing urine and meconium on the first day He eemed to be well for the first six days because he fed satisfactorily and was active having a normal Moro and grasp eflex; but he lost 10 oz. in weight, and by the eighth day 1/2 oz. more. By this time his temperature had begun to ise and he was sucking indifferently and was a little lehydrated.

Investigations and Treatment—Aureomycin therapy (25 mg our hourly) was started A white-cell count of 31 000 per .mm. (polymorphs 29% lymphocytes 52%) suggested an ctive infection, and streptomycin 125 mg daily was added o the therapy Tube feeding was started and subcutaneous aline solution was administered. The general condition emained stationary until June 15 when the infant s condition leteriorated and he had a convulsion Examination revealed ome neck stiffness Cisternal puncture produced clear anthochromic C.S.F. containing 4000 red cells and 54 white cells per c.mm (36 polymorphs and 18 lymphocytes per c.mm.) and protein 150 mg per 100 ml The possibility of virus meningitis or inclusion disease was considered at this stage

Course—There was rapid deterioration in the infant s condition and in six hours time the fontanelle was bulging and the baby showed severe opisthotonos. Cisternal and ventricular taps on this occasion revealed evenly bloodstained C.S.F. indicating subarachnoid hæmorrhage and the child died three hours later on June 16 1954 aged twelve days A necropsy was done by one of us (B. L. W.) next day

Necropsy Findings—The body was that of a mature male infant weighing 4 lb 15 oz and showing some wasting and dehydration. Petechiæ were present on the lower abdominal wall groins, and scrotum The *skull* was healthy with normal fontanelles The *brain* weighed 360 g and appeared swollen There was extensive subarachnoid hæmorrhage over the left cerebral hemisphere and in the cisterna magna. On section the third and fourth ventricles and both lateral ventricles were moderately dilated and contained blood the cut surface of the brain showed faint yellow discoloration. Situated in the occipital lobe of the right cerebral hemisphere lateral to the posterior horn of the lateral ventricle was an area of intracerebral hæmorrhage 2 cm. in diameter and communicating with the lateral ventricle Macroscopic examination of the *thoracic* and *abdominal viscera* showed no abnormality

Microscopy—At the site of intracerebral hæmorrhage there was destruction of the brain tissue; adjacent brain tissue showed œdema, capillary congestion and sparse infiltration by macrophages Overlying the left cerebral hemisphere and in the cisterna magna was hæmorrhage into the subarachnoid space Remote from the intracerebral and subarachnoid hæmorrhage the leptomeninges were congested and the subarachnoid space showed moderately severe lymphocytic infiltration There was also lymphocytic infiltration beneath the ependyma of the third and fourth and lateral ventricles Occasional blood vessels showed sparse perivascular lymphocytic cuffing Other tissues showed no significant abnormalities. No obvious cause was found for the intracranial hæmorrhage, which was thought to be due either to direct trauma (this seems unlikely in view of the situation) or, more probably to change of intracranial pressure following the first cisternal puncture

Virological Investigations—A specimen of C.S.F. taken from the infant on June 15 1954 was inoculated intracerebrally into mice from a L.C.M. free stock and intraperitoneally into guineapigs. Eight days after inoculation the mice were sick with symptoms described by Traub (1936) as typical of L.C.M. A suspension of brain material from sick mice of this group was specifically neutralised by L.C.M. immune serum Complement-fixing antigen prepared from the spleen of one of the two guineapigs killed on the sixth day after injection was also specific for L.C.M. The second guineapig bled from the heart fourteen days after inoculation, showed L.C.M. complement-fixing antibody in its serum. L.C.M. virus was also isolated from four pools of house mice caught in the mother s home

Discussion

Transplacental infection with L.C.M. virus has not hitherto been recorded although Traub (1939) and Haas (1941) have shown that it is the normal mechanism of infection in colonies of mice where the disease is enzootic

In the present case since the infant was separated from the mother immediately after delivery no possibility of postnatal infection exists. The possibility of paranatal infection must be borne in mind because it has often been stated that the urine in cases of human L.C.M. may contain the virus and thus the birth canal may have been contaminated Although it is well established that the virus is excreted in the urine of infected mice (Traub 1936) only one report has been published of the isolation of L.C.M. virus from the urine in man this is by Lépine and Sautter (1938) and appears to be of dubious validity

It therefore seems that transplacental infection was by far the most likely route in the present case, particularly in view of the fact that the major phase of the mother s illness occurred at least a week before delivery In this connection it is of interest to mention that Swarts and Kercher (1954) have published a case of transplacental infection with poliomyelitis virus

In further support of this view is the time of onset of the baby s illness. The incubation period of L.C.M. in man under natural conditions is extremely hard to establish, because in most cases there is repeated exposure in the home environment van Rooyen and Rhodes (1948) give it as one to three weeks. In the two cases of laboratory infection reported by Milzer and Levinson (1942) and Lépine and Sautter (1938) the most likely times of infection were six and ten days respectively before the onset of disease though both cases were continuously exposed to the possibility of infection before these times In one of the cases of Smadel et al (1942) the infection was apparently acquired while conducting a necropsy in a human case eight days before the onset of illness. In all these three cases it is probable that infection was by an artificial route. In the present case the onset of illness was only six days after birth, and we consider it most likely that infection was acquired during intra-uterine life.

Summary

A case of lymphocytic choriomeningitis in a newborn infant is reported.

The probability of transplacental infection is discussed.

Our thanks are due to Dr C S D Don and Dr J W A Hunter for access to the mother's case notes, and to Dr M O Adams for doing complement-fixation tests on the mother's serum and for investigating the house mice.

THE DIRECT FLOCCULATION OF INFLUENZA VIRUS

G BELYAVIN
M B Lond
SENIOR LECTURER IN BACTERIOLOGY, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, LONDON

By reason of its technical simplicity the direct agglutination reaction has been the serological technique of choice in both diagnostic and experimental bacteriology. In virology, however, its use has been restricted to the study of the plant viruses (Beale 1934, Bawden 1935), certain of the larger animal viruses, including the rickettsiæ (Otto and Dietrich 1917, Zinsser and Ruiz Castañeda 1932, Van Rooyen and Bearcroft 1943) and vaccinia (Ledingham 1931, Craigie and Tulloch 1931).

Agglutination of influenza virus was first reported over fifteen years ago (Magill and Francis 1938), but apart from additional observations by Henle and Chambers (1941) there has been no further development of this technique either as an adjunct to laboratory diagnosis or as a research tool. Such a possibility was suggested by the chance observation of typical flocculation in mixtures of highly purified virus and specific serum. I describe here the preliminary stages of an investigation designed to this end.

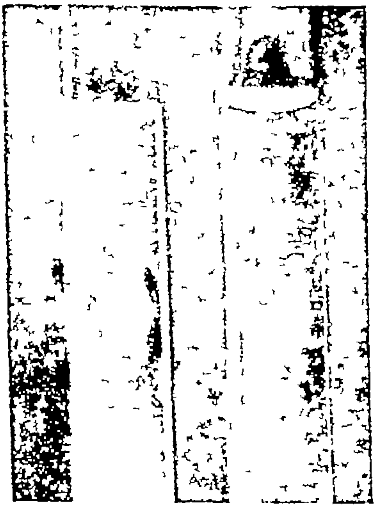

Fig 1—Fl... of eluate preparation of ... homologous antiserum ... 37°C.

Materials and Methods

Antigens

The following strains of influenza virus were used:

Type A PR8, received from the National Institute of Medical Research in 1947.

Type A "prime" FMI, obtained by the courtesy of Dr C H Andrewes from the World Influenza Centre.

MW, isolated in this laboratory in 1951 (Smith et al. 1951).

Ashby, isolated in this laboratory in 1953 and identified at the World Influenza Centre as a "Scandinavian" subtype (Isaacs and Andrewes 1951).

Type B Lee, received from the National Institute of Medical Research in 1947.

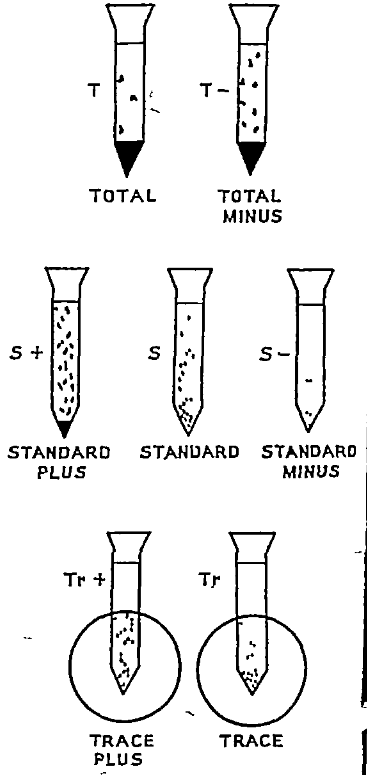

Fig 2—Defined degrees of flocculation of virus.

Viruses were grown by the allantoic inoculation of 11-day-old embryonated eggs with suitable doses of seed stocks kept at −70°C. They were used either as infected allantoic fluids or as partially purified and concentrated suspensions of virus in saline solution. Purification and concentration were achieved by either high-speed centrifugation or a single cycle of adsorption and elution from human red cells (Sheffield et al. 1954). Normal allantoic fluids clarified by centrifugation were also included as control antigens in certain experiments. When necessary, antigen preparations were stored at 2°C, and they retained their flocculability under these conditions for up to 6 or 8 months.

Sera

Rabbits were immunised by two intravenous injections of purified virus given at an interval of three weeks. The first injection was small, usually about 300 hæmagglutinating doses, and the second about ten times as great. Samples of serum were taken at convenient intervals after the first and second injections of antigen.

All the sera were inactivated at 56°C for 30 minutes and stored at −10°C without preservative.

Hæmagglutination

Virus antigens were conveniently standardised fo potency by hæmagglutination titration against fowl cel by the method of Belyavin et al. (1951). The titres serum which inhibited hæmagglutination by 4 agglutinating doses (A.D.) of virus were estimated by a simila technique.

Serum Absorptions

Virus, deposited from saline suspension by high spe centrifugation, was resuspended in appropriate aliquot of sera diluted 1/10 with physiological saline solutio and the mixtures were held at 4°C overnight. Next da the virus-serum mixtures were centrifuged at 22,000 for 1 hour to sediment the absorbing antigen. Th supernatant fluids constituted the absorbed antisera

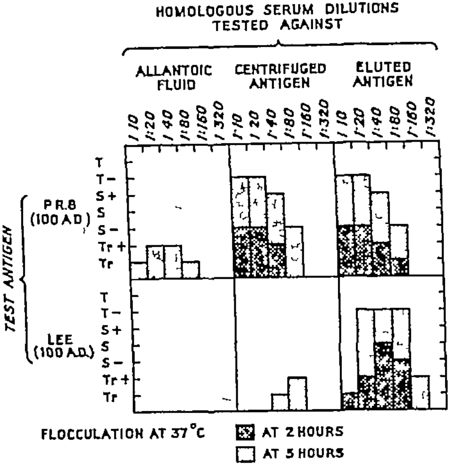

Fig 3—Relative speeds of flocculation of different preparations of influenza virus

Flocculation

Technique

Equal volumes (0 3 ml) of virus antigen and of serially diluted immune serum were mixed in Dreyer's tubes. The serum dilutions were pipetted first the virus antigen being added subsequently as in a bacterial agglutination test Orthodox controls containing only physiological saline solution and virus antigen were included in each test The rack was next placed in a water bath at 37°C the water level being adjusted to fall approximately between a third and a half of the way up the fluid column The tubes were inspected in a viewing box t short intervals

Development of Particulation

With suitable concentrations f antigen and serum there is a haracteristic sequence of events Within a few minutes after the tubes have been placed in the water bath at 37°C a faint opalescence develops which increases with time Eventually a fine granular precipitate forms; his is visible for a time only with a hand lens but develops subsequently into a well marked flocculation clearly visible to the naked eye It closely resembles a bacterial somatic agglutination (fig 1) the floccules sinking eventually to the bottom of the tube With a given antigen and antiserum a certain relative proportion of the two components gives the most rapidly particulating mixture and flocculation inhibition zones occur in the region of gross antibody or antigen excess Mixtures in the antibody excess zones usually show intense opalescence In these respects the reaction therefore behaves in the manner of a classical precipitin test Reduction of the amount of virus antigen added in a constant antigen titration leads to a smaller over all bulk of flocculum and the lowest concentration of antigen usable seems to be limited only by the detectability of the precipitate formed Antigen concentrations containing about 10–20 hæmagglutinating doses of virus per ml appear to be at the practical limit

Recording Degree of Particulation

In applying and studying this reaction it was found convenient to record the degree of flocculation observed in terms of a modified Dreyer's notation (Dreyer and Inman 1917) The defined degrees of flocculation are illustrated in fig 2

Effect of Virus Purification on Flocculation

Comparisons were made between the flocculability of infected allantoic fluid, high speed centrifugate, and eluted virus In each case an infected allantoic fluid was divided into three equal parts one part was clarified by centrifugation at 8000 g for 15 minutes one part was purified and concentrated fivefold by high speed centrifugation and the third part was treated by a single cycle of adsorption and elution also with fivefold concentration Samples of each preparation

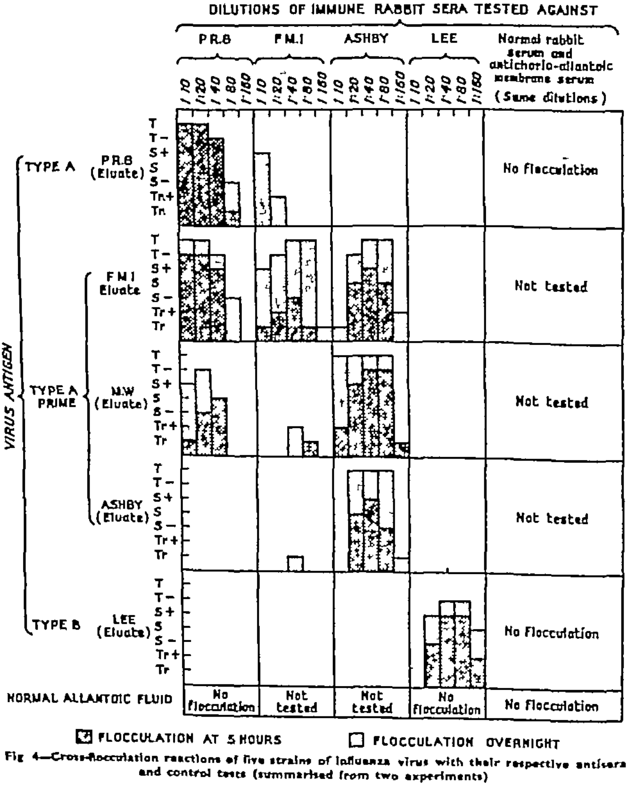

Fig 4—Cross-flocculation reactions of five strains of influenza virus with their respective antisera and control tests (summarised from two experiments)

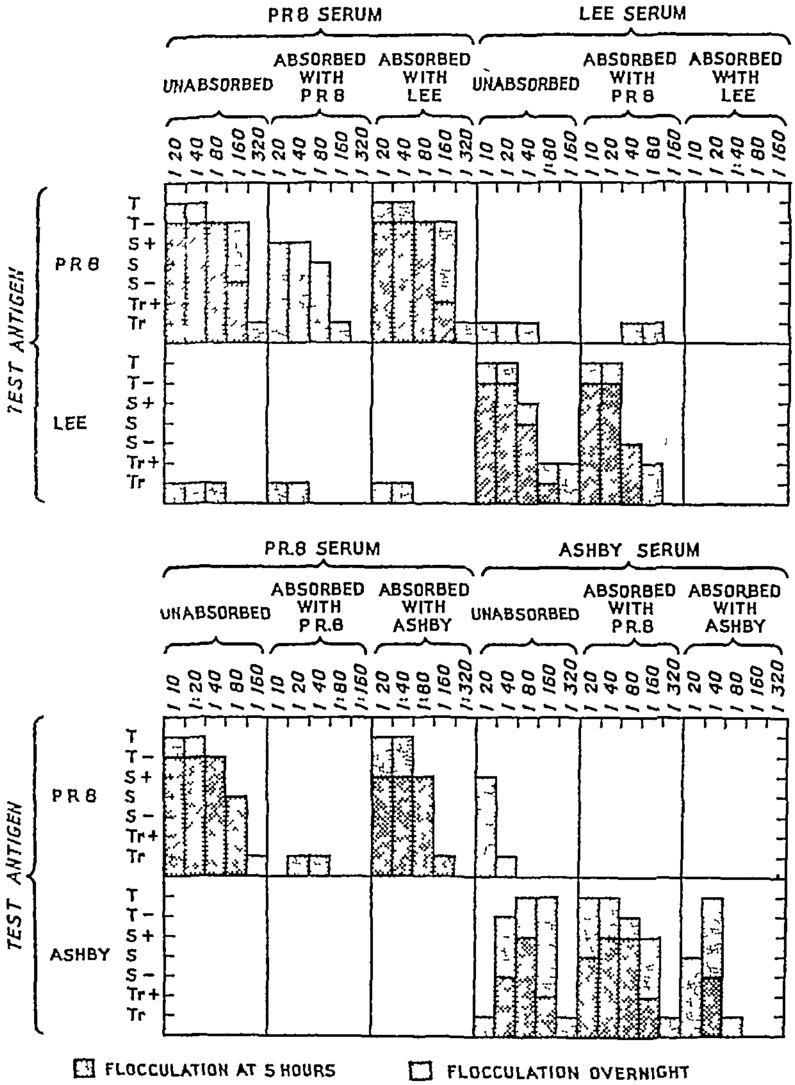

Fig 5—Results of two cross-absorption experiments using flocculation reaction to test absorbed sera.

adjusted by dilution to equivalent concentrations of virus in terms of hæmagglutinin, were compared for flocculability against serial bulk dilutions of homologous antiserum This was done using the PR8 and Lee strains, and an example of each (fig 3) shows the over all superiority of partially purified suspensions, which is notable in the case of some eluted preparations The poor flocculability of crude allantoic fluids relative to the purified virus suggests the presence of some material in the former which inhibits the reactions Probably such inhibitors present in crude preparations of virus explain the equivocal results of former workers

Experiments made with virus suspended in borate- and phosphate buffered saline solution showed that the rate and degree of flocculation were unaffected by differences of pH between 6 and 8

Specificity of Reaction

Reciprocal cross flocculation experiments were made with virus strains of distinguishable serological type and their homologous antisera In several of these experiments normal allantoic fluid, normal rabbit sera, and antisera prepared by immunisation of rabbits with saline extracts of normal chorio allantoic membrane were included as controls These latter were known to contain potent [illegible] fixing antibodies against membrane antig [illegible] ults of two such experiments (summarised in fig 4) show clearly the specificity of the reaction and the closenes with which it parallels the known serological pattern of the strains involved.

Serum Cross absorption Tests

The results of the cross-flocculation experiments were further confirmed by making reciprocal cross-absorption tests between viruses of distinguishable serological type and their respective antisera The absorbed sera were tested by full reciprocal cross flocculation reactions Two such experiments between a type A strain (PR8) and a type B strain (Lee) and between a type-A strain (PR8) and an A prime strain (Ashby) are illustrated in fig 5 These experiments fully confirmed the specificity of the direct cross flocculation experiments

Discussion

The experiments described show that the elementary particles of influenza virus are flocculated by specific antibodies Such a reaction has several practical applications A direct flocculation test of this nature, simple to perform and economical in apparatus and labour, will surely be of value in the routine serological typing of influenza virus Similarly, it may be applicable in the examination of post influenza convalescent sera and post vaccination sera, and a few preliminary experiments in this field encourage the view that this may be possible In a more academic field the technique provides another tool for the investigation of the nature and properties of the influenza viruses It may also be confidently anticipated that similar direct flocculation of many other animal viruses will be possible, provided that sufficiently purified and concentrated suspensions of virus can be prepared If they can, investigations of the effects of antigenic particle size on the dynamics of the specific precipitation reaction will be greatly facilitated For this reason, and in the hope of meeting urgent practical needs, the applicability of the present findings to the very small virus of poliomyelitis is now under investigation

Summary

The technique of a simple quantitative influenza vir flocculation test, using immune rabbit sera, is describe

The results of experiments which demonstrate i serological specificity and its inhibition by factors prese in normal allantoic fluid are presented, and the significance is discussed

I am indebted to Prof Wilson Smith for his critical advic The expenses of this work were defrayed by a department grant from the Medical Research Council

DEPOSITION OF IRON IN THE TESTES AFTER ADMINISTRATION OF AN IRON-DEXTRAN COMPLEX

J A. NISSIM
M.D Lond

SENIOR LECTURER IN PHARMACOLOGY IN THE UNIVERSITY OF LONDON AT GUY'S HOSPITAL MEDICAL SCHOOL, LONDON

PREVIOUS work with different iron preparations has shown that both the immediate and the later fate of iron in the body varies considerably depending not only on the size of the particle but also on the chemical nature of the non ionised compound (Nissim 1949 1953a) The study of iron uptake by the *testis in experimental siderosis* was stimulated by the earlier finding of a close correspondence in the distribution of saccharated iron oxide and of ascorbic acid in many organs (Nissim 1952a) It was found however that although iron appeared in a few histiocytes scattered among the interstitial tissue of the testis in a few days after the intravenous injection of saccharated iron oxide *most of the interstitial cells,* presumably endocrine remained entirely free from iron n later work moderate uptake of iron by the endocrine nterstitial cells was noted after repeated injections of he diffusible preparations ferric hydroxide ferrous ascorbate and ferric chloride caramelate (Nissim 1953b)

I report here the striking deposition of iron in the interstitial cells of the testis after the administration of the iron-dextran complex Imferon a deposition more massive than that in *any other organ in the body*

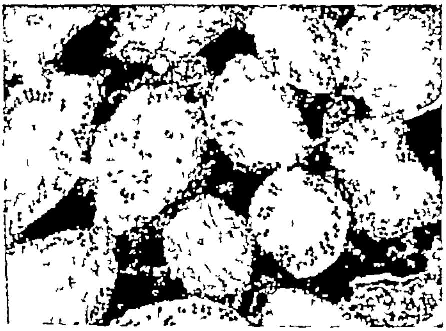

Fig 1—Testis of mouse showing massive deposition of iron in proliferated interstitial tissue with severe degeneration of seminiferous tubules and absence of spermatozoa after administration of 3 g of iron (as imferon) per kg of body-weight in six intravenous injections given twice weekly *Mouse was killed 11 weeks after last injection.* (Prussian-blue and carmalum. x 148.)

Methods

The iron-dextran complex was injected intravenously into white adult male mice in doses of 0 5 g of iron per kg of body weight weekly or twice weekly Some mice received similar doses subcutaneously Sections of the testes were studied at 3 4 and 24 hours, 4 days, and 2 weeks after single doses The total amount of iron given in repeated injections was 1, 2 and 3 g per kg of body weight and the mice were killed up to 10 weeks after the last injection

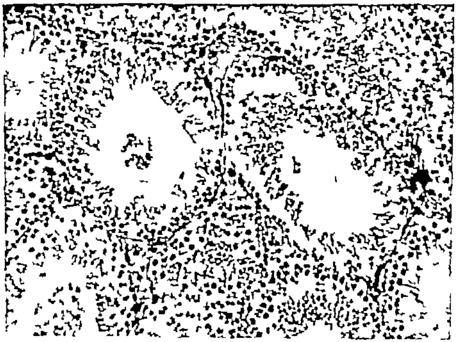

Fig 2—Testis of mouse showing heavy iron deposition in some interstitial cells and light staining of the rest of the interstitial tissue. *Note darkly staining fluid in one of the interstitial-tissue spaces.* Mouse received 0 5 g of iron (as imferon) per kg of body-weight in a single intravenous injection and was killed a fortnight later (Prussian-blue and carmalum. x 148.)

Results

All mice receiving repeated doses of imferon showed striking testicular atrophy, whose progress was followed easily by palpation The severity of atrophy depended on the total dose as well as the duration of siderosis The weight of testes showing maximal atrophy was 25–30 mg compared with 90–120 mg of the controls Sections revealed *increasing* degrees of iron *deposition* in the interstitial cells and correspondingly increasing damage to the seminiferous tubules with striking effect on spermatogenesis (fig 1) There was *in addition* an increase of interstitial tissue presumably as a result of replacement regeneration Tubule cells showed some iron staining in advanced interstitial siderosis.

Sections taken at intervals after single doses showed iron in the extravascular interstitial histiocytes as early as three hours after the injection when most of the iron was still in the circulation The prussian blue staining revealed in the interstitium spaces (figs 2–5) containing

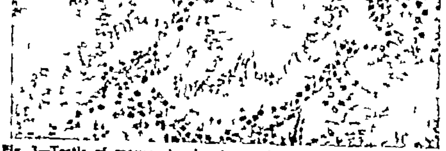

Fig 3—Testis of mouse showing heavy deposition of iron in some interstitial cells presumably mainly histiocytes, without staining *of the rest of the interstitial tissue* Note interstitial spaces containing fluid stained darkly with prussian-blue. Mouse received 0 5 g of iron (as imferon) per kg of body-weight in a single intravenous injection and was killed 4 days later (Prussian-blue and carmalum. x 148.)

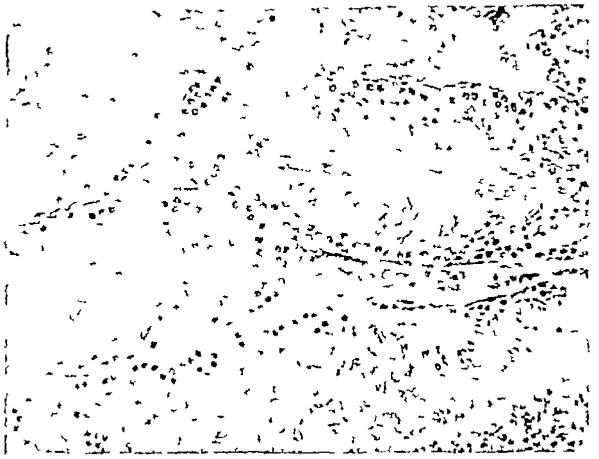

Fig 1—Testis of mouse showing uptake of iron by few histiocytes in the interstitial tissue, and blue-staining fluid in spaces In one space fluid surrounds a medium-sized vessel, which contains iron-staining plasma near the upper edge Mouse received 0 5 g of iron (as imferon) per kg of body weight in a single intravenous injection and was killed 4 hours later (Prussian blue and carmalum × 148)

fluid which bathes islets of interstitial tissue The staining in this fluid was initially as intense as that in the plasma, but, as the iron disappeared from the vessels, the fluid in the interstitial tissue spaces continued to show much iron staining With passage of time the endocrine interstitial cells exhibited increased iron staining and the number of cells with iron deposition comparable to that of histiocytes also increased These latter cells may be either proliferating histiocytes or the old endocrine interstitial cells that have become saturated with iron, but, since little histiocyte proliferation takes place in the testes after the administration of other iron preparations, the hypothesis of endocrine origin of these cells seems more likely

Discussion

Though these experiments do not suggest that a significant amount of iron may accumulate in the interstitial cells of the testes after therapeutic administration of imferon in man, the early appearance of the compound in the histiocytes and fluid spaces of the testes is possible In anæmia, however the iron is probably soon mobilised for the synthesis of hæmoglobin

Control experiments with saccharated iron oxide showed no iron in the interstitial histiocytes of the testes or in the fluid spaces until a few days after the injection, when some of the iron has been solubilised by the intravascular histiocytes which form the primary site of deposition Thus, the early appearance of imferon iron in the histiocytes and fluid spaces of the testes suggests a smaller particle size This was confirmed by the injection of the diffusible iron and ammonium citrate into mice Owing to greater toxicity the doses given were much smaller, but histiocyte uptake was shown as early as 1½ hours after the injection, and the fluid was visible in the interstitial spaces after an immediately lethal dose

The later stages in imferon siderosis lend themselves to ferent interpretations, but the continued presence staining fluid in the interstitial spaces suggests is continually transferred from the histiocytes ndocrine cells The progressive increase of the n in the interstitial tissue in turn suggests that also continually transported to the testes from arts of the body The iron compound apparently ers with the normal metabolism of the endocrine Whatever the mode of action the iron complex ges the seminiferous tubules and upsets spermato is The mode of action is a matter for further tigation

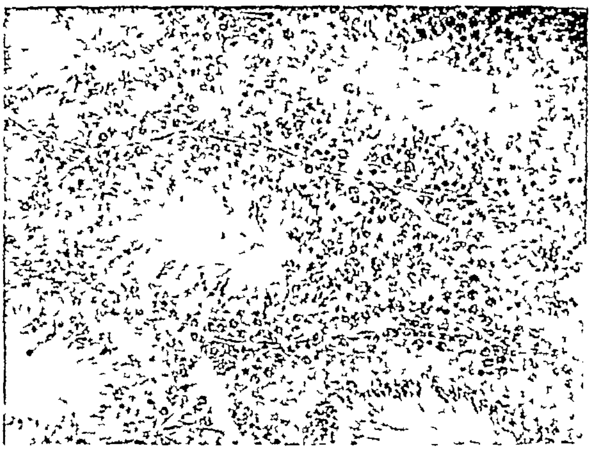

Fig 5—Testis of mouse showing absence of iron staining from a interstitial cells including histiocytes Compare normal seminiferou tubules and spermatogenesis with tubules in fig 1 Animal receive 0 5 g Fe /kg as saccharated iron oxide intravenously and was kille 4 hours later (Prussian-blue and carmalum × 148)

The deposition of iron in the testes after the adminitration of imferon reminds one of the deposition of iro in the testes and testicular atrophy in hæmochromatosis No deposition of iron has been noted, however, in th pituitary gland, the thyroid gland, or the islets o Langerhans after the administration of imferon, therefore the mechanism of the two conditions must differ

The ovaries of mice did not exhibit unusual affinit for imferon, the deposition of iron in them being simila to that described previously for saccharated iron oxid (Nissim 1952b)

Summary

Massive deposition of iron took place in the interstitia cells of the testes in experimental siderosis of mice wit imferon

This was associated with severe testicular atrophy an degeneration of the seminiferous tubules

I wish to thank Messrs Benger for the imferon used i these experiments

ACCIDENTAL INOCULATION WITH POLIOMYELITIS VIRUS

W F Twining McMath
M.D Belf, M R C P, D P.H
PHYSICIAN SUPERINTENDENT NEASDEN HOSPITAL, LONDON

The development of poliomyelitis in laboratory workers exposed to virus has rarely been recorded Sabin and Ward (1941) recorded the case of a laboratory associate, aged 35, who contracted paralytic poliomyelitis, probably in the course of her work on cynomolgus monkeys Two laboratory workers were reported by Beller (1953) to have been accidentally infected in the eyes and nose with Lansing virus while inoculating mice with a virulent mouse brain suspension, both developed symptoms after fourteen days

In the following case a technician was infected through accidental abrasion of a finger

A laboratory technician, aged 22, was admitted to Hospital on Nov 11, 1954 He had been employed in a research unit, and among his duties was the necropsy of animals dying after inoculation with poliomyelitis virus On Nov 1 he was removing the spinal cord from a monkey which had ecome paralysed and had died after repeated intramuscular oculation of a tissue-culture of propagated M.E.F 1 strain virus (type 2) The patient sustained a small abrasion of finger with a bone spicule from the vertebral column this ook three days to heal He was given gamma globulin 5 ml (1 5 g) intramuscularly on the same day and was uite well until Nov 9 when he complained of headache and umbar pain The following day he also had pain and enderness of abdominal muscles

On admission he had a temperature of 102 F slight neck tiffness, and a positive Kernig s sign. The neck stiffness leared up the next day, but the tenderness and spasm of bdominal and hamstring muscles continued for another week The erythrocyte-sedimentation rate was 1 mm in the first our (Westergren) White blood cells numbered 3800 per mm (70% polymorphs, 21% lymphocytes, 7% monocytes 2% eosinophils) Lumbar puncture was not carried out on dmission, but on Nov 25 the cerebrospinal fluid contained 250 lymphocytes per c.mm., 70 mg protein per 100 ml 720 mg chloride per 100 ml. and 70 mg sugar per 100 ml culture was sterile The complement fixation antibody investigations on serum taken on the third and twenty-eighth days of the illness did not by themselves lend convincing support to a diagnosis of recent systemic infection with poliomyelitis virus.

During the patient s illness there was indefinite weakness of the extensor muscles of the fingers of both hands His further progress was uneventful, and he was discharged for convalescence on Dec 12

Poliomyelitis was not epidemic in the district and it is reasonable to assume that the patient contracted poliomyelitis by infection through the accidental scratch The administration of gamma globulin on the same day as the injury did not prevent the illness from developing after eight days incubation though it may have lessened its severity

I wish to thank Dr W Wood for the history of the patient especially with reference to the administration of gamma globulin and Dr G L Le Bouvier, of the Virus Reference Laboratory Colindale for the serum complement fixation antibody investigations.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Osteoporosis

THE section of medicine met on March 22 with SIR HENRY COHEN the president in the chair to discuss Osteoporosis

Dr H A SISSONS defined osteoporosis as a condition of bone where the supporting tissue was reduced but remained highly mineralised and where sections did not reveal the broad osteoid seams which characterised osteomalacia Osteoporosis was a non-specific pathological response In examples of the local osteoporosis of disuse, where thin slabs of bone had been radiographed and then studied histologically the initial lesions were found to be localised areas of osteoclastic bone destruction in the chronic stage the changes were more diffuse and the porotic bone showed neither destruction nor formation of bone

In Cushing s syndrome an excess of adrenocortical hormone produced generalised osteoporosis The bony trabeculæ were thin and reduced in number excess osteoclasis was not apparent but osteoblastic bone formation was diminished Radiographs of slabs of the vertebral bodies showed that the trabeculæ at first lost their normal orderly arrangement and then broke under the force of compression so that the vertebral bodies collapsed

Dr Sissons regarded osteoporosis as an imbalance in the normal process of continuous bone destruction and formation in favour of destruction

Dr C E DENT discussed diagnosis He followed Albright s definition—a deficiency of the protein matrix of bone without abnormalities in the mineral elements The calcium phosphorus and phosphatase contents of the blood were normal He emphasised that the term was not to be used to cover any rarefaction of the bones which could result from osteomalacia (where the calcification of bone was at fault) from hyperparathyroidism (where there was an abnormal removal of calcium from the skeleton) or from neoplastic diseases of bone The diagnosis depended first on recognising that rarefaction of the skeleton had taken place The early changes were purely radiographic but collapse of vertebræ could be diagnosed by finding a reduction in the distance from the crown to the pubis which normally equalled that from the pubis to the heels and in the distance from the crown to the heels which normally equalled the span In osteoporosis some vertebræ were more rarefied and distorted than others in osteomalacia the vertebræ were more evenly affected The diagnosis of osteoporosis was by exclusion—a dustbin for those rarefactions of bone that could not otherwise be explained Some cases were indistinguishable from the late form of osteogenesis imperfecta

Dr Dent had not had much success with treatment in 4 cases of idiopathic osteoporosis which he had studied in detail but 1 had responded remarkably to repeated large infusions of plasma

Dr PAUL FOURMAN discussed endocrine aspects. The present-day definition of osteoporosis had been followed by several pupils of von Recklinghausen twenty five years ago Albright had sought to relate the condition to endocrine factors and had suggested that the failure of the bone matrix could be the result of a lack of anabolic hormones the N hormone of the adrenal cortex and the gonadal hormones it could, on the other hand, result from an excess of anti anabolic hormone, the 'S hormone of the adrenal cortex

Osteoporosis in old age was probably a manifestation of the normal atrophy of the tissues associated with ageing It could be perhaps related to a failure of adrenal N hormone production Senile osteoporosis was much commoner in women and when it appeared early it was called postmenopausal but Dr Fourman doubted whether it could be attributed to a lack of œstrogens, although œstrogens often relieved the pain The response to androgens was better still, but it was rare to find that the bones became denser

Dr Fourman demonstrated the osteoporosis of Cushing s syndrome and of acromegaly and mentioned the osteoporosis of diabetes Thyrotoxicosis did not produce osteoporosis as the speakers had defined it but it produced an excessive osteoclasis On the other hand cretins sometimes had osteoporosis and he had seen it in a patient with myxœdema He thought osteoporosis was a non-specific response to various different disturbances in the nutrition of the tissues

In the discussion Dr DONALD HUNTER emphasised that further advance depended on finding ways of measuring the changes. He appealed for the use of the band saw in the necropsy room Dr A W SPENCE agreed with Dr Hunter that in thyrotoxicosis there was excessive bone destruction He asked whether with methyl androstenediol one might achieve the same benefit as with androgens without the complication of masculinisation Dr B E C NORDIN suggested that the atrophy of the bones in osteoporosis might be in proportion to the atrophy of other protein tissues and that osteoporosis was but a symptom of disease affecting the whole body Insufficient attention had been paid to possible changes in the polysaccharides of bone matrix

Reviews of Books

Pædiatrics for the Practitioner

Vol I II, III and Index General editors WILFRID GAISFORD MD MSC, FRCP, professor of child health and pædiatrics University of Manchester, REGINALD LIGHTWOOD, MD, FRCP, DPH, director of pædiatric unit, St Mary s Hospital medical school London Butterworth 1955 Pp 1849 £13 10*s* the set

THIS ambitious work has now been completed by the publication of the third volume, the first having appeared in 1953 It epitomises the increasing emphasis on the promotion of good health in childhood, and is the first major pædiatric textbook to be written specially for general practitioners

It is comprehensive without being too detailed, and embraces such subjects as growth and development, the care of the newborn and normal child, social medicine, and psychology, as well as general medicine and surgery There are also chapters on disorders of the skin, eyes, ear, nose, and throat, and teeth The fifty two contributors, under the general editorship of Professor Gaisford and Dr Lightwood have concentrated on practical aspects, particularly the diagnosis and treatment of the common disorders of infancy and childhood, rare conditions are mentioned briefly to complete the picture Special attention is given to domiciliary treatment by the general practitioner, because the discovery of more potent drugs is increasing the proportion of illnesses which can be treated successfully at home This work is to be kept up to date by supplements which should enable the practitioner to keep abreast of changes

These volumes, well produced and liberally illustrated, should prove of great value to general practitioners in this important and satisfying field of medicine

Biochemical Determinants of Microbial Diseases

RENÉ J DUBOS, The Rockefeller Institute for Medical Research Cambridge, Mass Harvard University Press London Oxford University Press 1954 Pp 152 28*s*

THE substance of this book is a series of lectures given in 1953 on the occasion of the award of the Warren triennial prize of the Massachusetts General Hospital In *The Bacterial Cell* (1945) Dr Dubos examined some of the problems of infectious disease in relation to the form and habits of the parasites In this book his inquiry is directed to the part played by the host's internal economy in the prevention or encouragement of damage by the parasites Together the two works are a distinguished ornament to the "newer bacteriology" The keystone of the argument lies in the sentence " infection is in many cases the normal state, it is only disease which is abnormal" It is the end of the old anthropomorphic view that simplified all infectious processes to a war between an intact body and innumerable hostile invaders

Although much of the evidence is chemical the outlook is that of a biologist, and indeed some of the matter is drawn from fields outside the experience of most bacteriologists Dr Dubos modestly but sternly refuses to make dogmatic generalisations but throughout there flows a sparkling stream of suggestive hints and theses presented for disputation

It is a very proper book to put in the hands of him who imagines that all the fields for research are already under cultivation Others will regret their limitations of time and intellect but be grateful to the author for an exciting experience The writing is lucid if sometimes inelegant The make up is pleasant, but the price lamentably high

The Histopathology of the Respiratory Tract in Human Influenza

J F PH HERS, MD Leiden H E Stenfert Kroese 1955 Pp 77 17 50 Dutch florins

THIS is an excellent monograph It records a detailed examination of the epithelium of the respiratory tract in twelve cases of influenza, of which seven were complicated by infection with staphylococci and five with other bacteria The changes are compared with those found in four cases of fatal infection with *Hæmophilus influenzæ* and pneumococcus unassociated with influenza virus The coincident focal necrosis and regeneration is typical of, but not confined to, influenza, for the same appearances have been found in measles and varicella Examining smears of tracheal epithelium is valuable for rapid post-mortem diagnosis, and characteristic cytological changes can be recognised in the sputum during life The monochrome reproductions of the photomicrographs are good, and the method of placing them at the back of the book is unusual and effective

A Therapeutic Index

C M MILLER, MD Lond, MRCP, consultant physician, Sefton General Hospital, Liverpool, B K ELLENBOGEN, MD Lpool, MRCP, senior medical registrar, Royal Southern Hospital, Liverpool London Baillière, Tindall, & Cox 1955 Pp 148 12*s* 6*d*

IN this gallant attempt to compress modern therapeutic opinion into the space of a pocket-sized volume Dr Miller and Dr Ellenbogen have achieved comprehensiveness without undue sacrifice of detail no mean feat, for the territory is immense, the byways innumerable, and the main thoroughfares themselves sometimes hard to follow By describing only the more prominent landmarks (ancient monuments excepted) they have provided the young houseman or practitioner with a sensible and reliable Baedeker The book is likely to prove most valuable in emergencies, when there is no time to consult the larger textbooks, but it will also be read with profit in moments of leisure, for it contains some useful hints on practical procedures and therapeutic diets

Il Sistema Istiocitario

PIETRO FRANCESCHINI Florence Edizioni Scientifiche Salpietra 1954 Pp 883 L 12,000

THIS is a Florentine *cimento*, a " bold venture," by an anatomist and surgeon distinguished for his studies on the histiocytic tissue of synovial membrane, the reactivity of the peritoneum, and the histiocytic structure and function of the leptomeninges Dr Franceschini is a pupil of Chiarugi and Banti, and his book will interest specialists in many branches of physiology and pathology The book is a comprehensive account of the reticulo-endothelial system, and a valuable record of much fine, though little-known, Italian research

The first half deals with general topics, such as the relation of the reticulo-endothelial system to tissue permeability, blood coagulation, the destruction of erythrocytes, infectious diseases, antibodies, intermediary metabolism, occupational and systemic diseases, and antineoplastic resistance The second half is specialised, and includes chapters on the reticulo-endothelial system in the fœtus and placenta, skin, bone, synovial membrane, and peritoneum An appendix describes the part of the microscope in the history of biology Like many of his medical compatriots, Dr Franceschini has a historical sense, which he reveals with grace and modesty, with them he also shares a taste for controversy and a passionate concern for precise terminology, exemplified in a whole chapter on the definition of the reticulo endothelial system The chapter on Banti's disease will be of wide interest outside Italy It is a relief to find that we are not the only people who do not know what Banti's disease is, an Italian has concisely defined it as the tormented history of a genial pathogenetic conception

The book has 270 illustrations and ample subject and author indexes, it is well printed on good paper, and strongly bound

Studies on Fertility —This sixth volume of the proceedings of the Society for the Study of Fertility, hitherto published in journal form, includes papers read at the conference held by the society in London last year The editor is Prof R G Harrison, DM (Oxford Blackwell Scientific Publications 1954 Pp 151 21*s*)

Fat Metabolism —The Johns Hopkins Press, Baltimore, has published a symposium on this subject, which was one of a series of conferences sponsored by the M & R Laboratories Columbus, Ohio The editor is Mr Victor A Najjar It is published in this country by the Oxford University Press (1955 Pp 185 36*s*)

THE LANCET

LONDON SATURDAY APRIL 2 1955

Nomenclature and Colon Disorders

STUDY of inflammatory conditions in the colon is bedevilled by the nomenclature, or the lack of it. Because of the naked-eye appearance of the large bowel of patients with chronic non-specific diarrhœa, WILKS and MOXON[1] introduced the term ulcerative colitis. The name having been given, the condition was assumed to be a disease *sui generis*. Consequently the question is not uncommonly asked: What is the cause of ulcerative colitis?; whereas the causes are probably many. There was BARGEN's bacillus; there is the school of allergy[2 3]; there is evidence that physical[4] and chemical[5 6] agents can precipitate the condition; and long ago SYDENHAM[7] stated: "Sometimes though very rarely it happens that a dysentery, not rightly cured originally, shall afflict a particular patient for many years"—an observation supported by STEWART,[8] FELSEN and WOLARSKY,[9] and HURST.[10] All these explanations may be right; certainly the histological evidence would support them all, for in the first instance ulcerative colitis appears to affect the mucosa, which like the skin may be subject to many forms of trauma and once severely damaged may remain unhealed.

Confusion has been increased by the response to the need for more titles. When CROHN[11] first described 14 cases of regional ileitis the name seemed to be no problem; but later it was realised that the colon could be involved, with or without a small-bowel lesion, and then the terms "regional enteritis" or "regional colitis" were brought into use. "Regional colitis" can also indicate ulcerative colitis proper; and BARGEN, who is convinced that ulcerative colitis starts in the rectum, has used this term for cases in which that organ is not involved. "Regional (segmental) colitis," he says, "may be defined as an inflammatory disease of unknown etiology involving initially one or more segments of the large intestine exclusive of rectum and recto-sigmoid, either as a continuous lesion or as multiple discontinuous lesions"[12]—a definition that includes both Crohn's disease and ulcerative colitis. Some may indeed regard with reserve the separation of Crohn's lesion from ulcerative colitis. Yet there are clear differences. To the naked eye they do not resemble each other; for, in contradistinction to the findings in ulcerative colitis, in Crohn's disease the bowel wall is thickened throughout all layers, the bowel tends to adhere to adjacent viscera and to become the site of fistulæ, and the limits of the lesion are well defined except for minute ulcers which are sometimes seen beyond the area of gross change.[13] The histological evidence of WARREN and SOMMERS[6] suggests that morphologically Crohn's disease is quite distinct from ulcerative colitis, while HADFIELD[14] maintains that in Crohn's disease mucosal ulceration is a secondary change not present at the outset. In ulcerative colitis the ileum may be involved as in Crohn's disease; but BROOKE[4 13] has shown that such involvement is incidental to the destruction of the ileocæcal valve by long-standing disease—a finding confirmed by INBERG.[15] Clinically, the complications of arthritis, iritis, and skin lesions are found only in ulcerative colitis. CROHN himself, reflecting on 562 personal cases, still feels justified in classifying the condition named after him as a pathological and clinical entity.[16]

COOKE and BROOKE[17] have now given a fuller account of a condition not unlike ulcerative colitis which they had already mentioned briefly.[18] Steatorrhœa is not a feature of ulcerative colitis even when the terminal ileum is invaded, unless there is associated pancreatitis. COOKE and BROOKE have seen 16 patients with frank steatorrhœa in whom there was radiographic and sigmoidoscopic evidence of colitis. In 2 cases diffuse ulceration of the small bowel was found at necropsy. There was little or no thickening of the wall of the small gut, and indeed there was no evidence of the lesion there until the intestine was opened for inspection. In this respect it differed from Crohn's disease. Ileitis secondary to ulcerative colitis is limited in extent and rarely involves more than a foot of intestine; but in their patients with steatorrhœa the small bowel was involved throughout. In the colon the right side seems to be attacked first; the inflammation then spreads distally. They therefore suggest that the colitis is secondary to the small-bowel disorder. The importance of this unusual condition lies in its close resemblance to ulcerative colitis—particularly that subgroup previously called right-sided colitis, which COOKE and BROOKE suggest, may be the same disease. The usual surgical treatment of ulcerative colitis proper may bring disaster in such cases; they argue that deaths from ileitis after ileostomy have included cases in which this condition was mistaken for ulcerative colitis and the small-bowel lesions passed unnoticed. Meanwhile yet another name has been added to the terminology; for what was at first called ileocolitis[18] COOKE and BROOKE now use the term non-specific enterocolitis. Ileitis secondary to ulcerative colitis could perhaps be suitably termed colo-ileitis, thus reserving ileocolitis or enterocolitis for conditions in which the small intestine is known to be affected primarily and the disease usually spreads distally.

Diuresis from Carbonic Anhydrase Inhibition

THE side effects of the early sulphanilamides included a metabolic hyperchloræmic acidosis[1] associated with alkaline urine[2] and increased urinary excretion of sodium and potassium[3 4] Later MANN and KEILIN[5] showed that sulphanilamide and its amino substituted derivatives inhibited specifically the enzyme carbonic anhydrase, which was demonstrated in the renal cortex[6] HOBER[7] linked these various observations by adding sulphonamides to fluid perfusing frog kidneys and showing that the normally acid urine was rendered alkaline by derivatives capable of inhibiting carbonic anhydrase PITTS and ALEXANDER[8] proved conclusively that acidification of urine depended on the active secretion of hydrogen ions into the tubular urine by cells of the renal tubules Sulphanilamide given to acidotic dogs both alkalinised the urine and increased excretion of bicarbonate bound base These studies, and their subsequent extension by PITTS[9 10] and BERLINER et al[11 12] have provided considerable insight into renal tubular mechanisms concerned with conservation of base It is now believed that one of the most important mechanisms by which Na^+ is reabsorbed from the glomerular filtrate is by exchange with H^+ and K^+ secreted into the lumen by tubule cells, whether the cation exchange of Na^+ is predominantly with H^+ or K^+ is apparently determined by the relative availability of these two ions within the tubular cells[13] Availability of renal-cell H^+ is determined by carbonic anhydrase through the following reaction sequence

$$H_2O + CO_2 \underset{\text{anhydrase}}{\overset{\text{carbonic}}{\rightleftharpoons}} H_2CO_3 \rightleftharpoons HCO_3^- + \underset{\substack{\downarrow \\ \text{secretory} \\ \text{exchange with } Na^+}}{\textcircled{H^+}}$$

Nothing is known of the biochemical mechanisms involved in the H^+/Na^+ cation exchange, but when available H^+ is reduced by carbonic-anhydrase inhibition or by reduction of CO_2 tension,[14] the over-all tubular reabsorption of Na^+ is reduced and sodium excretion increases Obviously, one way of promoting the renal excretion of sodium would be by deliberate inhibition of carbonic anhydrase

The possible therapeutic value of the diuretic action of sulphanilamide was recognised by SCHWARTZ,[15] who administered the drug to patients with congestive cardiac failure and recorded increased urinary output of sodium and potassium, together with significant loss of weight But, though the results were promising, the drug was too toxic in the large doses that were needed Since 1950 a relatively non-toxic heterocyclic sulphonamide, acet zoleamide (2 acetylamino-1,3,4-thiadiazole 5 s amide, compound '6063' or 'Diamox') has intensively investigated[16–26] Acetazoleamide is highly potent reversible inhibitor of carbon anhydrase which can be given by mouth[23] It absorbed rapidly and is stable in the body, it i excreted relatively slowly by the kidneys, and more than 70% of the administered dose is recovered in the urine within twenty-four hours[23] After a single dose of 250 mg the rate of excretion of sodium, potassium, bicarbonate, and water increases, the urine becomes alkaline, and excretion of ammoni and titratable acid is reduced[18 21 23 25] Which cation is principally excreted with bicarbonat depends partly on previous dietary intake, i potassium deficiency sodium-bicarbonate excretio is favoured,[13] and in sodium depletion potassium bicarbonate excretion[21] Toxic effects are uncommo and and slight[23] Drowsiness, or even quite dee sleep, has been experienced by some patients in mos large series studied[16 17 19 26], and apparently harmless paræsthesiæ, in the form of tingling or numbnes in hands and feet or about the mouth, are no uncommon[16 17 22 26] More serious cerebral symptoms such as toxic psychosis, are exceptional[23] Togethe with the other toxic symptoms, they suggest a direc action of the drug on the nervous system, they ar reminiscent of the occasional toxic psychosis an polyneuritis produced by the parent sulphanilamid The drowsiness and paræsthesiæ subside after withdrawal of the drug No peripheral motor symptom have been recorded Only one case of agranulocytosi has been recorded, the patient recovered[27]

It is thus evident that acetazoleamide has theoretic pharmacological qualifications as an oral diureti All workers agree that a single dose in healthy peop or œdematous patients will produce the diuret effects already described, the maximal rate and tot amount of bicarbonate excretion after a single dos show the usual logarithmic relation to dosage bot in man[21] and in the dog[23 25] But most worke also agree that the drug becomes ineffective o repeated administration, owing to the developme of hyperchloræmic acidosis[16 18 25 26] The diureti effect is determined by the amount of bicarbonat filtered by the renal glomeruli,[21 28] and either reduction in plasma-bicarbonate level or the reductio in glomerular filtration-rate that accompanies cardia failure will reduce the diuretic response Since th drug produces hyperchloræmic acidosis, it is self inhibitory, and, in balance experiments, continued administration produces no increase in sodium excretion after the first day, although a slight sustained negative potassium balance may result[18 21 25] At

rst sight, therefore, the theoretical pharmacological ualifications are not borne out by clinical trial, ut, as often happens, clinical use introduces variables ot anticipated in the controlled experiment, and ublished clinical reports neither entirely support he pessimistic conclusions of the clinical investigator or agree with each other Consequently it is not yet ossible to assess the drug as a diuretic or to suggest uitable dosage Opinion on diuretic effectiveness aries from virtual nihilism [21] to considerable enthusiasm [16, 17, 22], and dosage has ranged from a single ablet of 250 mg, with at least a day between doses, o the continued administration of up to 6 g a day [22]

Amid this uncertainty a few points stand out learly With moderate continued dosage (up to 2 g a day in divided doses) no impressive diuretic response may be obtained in congestive cardiac failure due to hypertension or valvular disease [18, 21], but in "resistant" cases the drug may none the less alkalinise the urine and promote the excretion of large amounts of potassium [16, 21] This potential hazard should be borne in mind, and although potassium deficiency from this cause has not yet been recorded in man, it has been produced experimentally in the dog [23, 25] Patients previously resistant to mercurial diuretics may regain responsiveness when a relatively ineffective course of acetazoleamide has produced hyperchloræmic acidosis [19] Better therapeutic results seem to be obtained with moderate dosage in patients with congestive cardiac failure due to cor pulmonale [20, 24] a significant clinical diuretic response may ensue in about a half of such patients.[20] This better response is understandable if diuresis is determined by the load of bicarbonate filtered by the glomeruli The high plasma bicarbonate level in respiratory acidosis is determined by the high carbon-dioxide tension in the renal parenchyma [29] consequently it may be found that larger doses of acetazoleamide are needed to inhibit renal carbonic anhydrase in cor pulmonale The urine reaction and the rates of excretion of ammonia and titratable acid return to normal during continued acetazoleamide treatment [8, 21, 23, 25] and so although there is continued systemic acidosis there are no secondary effects on calcium and phosphorus metabolism such as occur with the hyperchloræmic acidosis of renal tubular acidosis.[23]

When acetazoleamide leads to a successful diuretic response in cor pulmonale [20] or in other types of congestive failure,[22] with weight loss and disappearance of œdema, it has obviously set off the renal excretion of chloride in addition to bicarbonate Nothing in the experimental investigations of the drug lead one to expect this effect, and there is need for careful documentation of the pattern of urinary excretion during the development of such responses Other aspects of chloride metabolism during acetazoleamide therapy warrant further investigation. The hyperchloræmic acidosis of continued drug administration develops without change in external chloride balance,[18, 21, 25] and it is usually ascribed to contraction of extracellular fluid volume after the renal loss of sodium bicarbonate yet the findings of LEAF et al.[18] suggest that a similar acidosis may ensue in patients showing diuresis only of potassium bicarbonate This explanation of the development of hyperchloræmia, and the identical explanation offered for the hyperchloræmia of renal tubular acidosis,[30] seem a little too facile It used to be thought that the hypochloræmia of potassium deficiency was the outcome of a negative chloride balance, we now know that this change may be associated with an actual chloride retention,[31] and during development of potassium deficiency chloride may be transferred into the inulin space from some other source of body chloride [32] Is it possible that shifts of body chloride take place during acetazoleamide therapy? Why should hyperchloræmia persist during therapy once the urine pH and excretion of ammonia and titratable acid have returned to normal? What renal change conditions this tolerance of a high plasma chloride level? These questions are far from purely academic, for we cannot hope to dispose of massive œdema unless we promote the excretion of chloride in addition to that of sodium.

EFFECTS OF EXPOSURE TO NUCLEAR RADIATION

ON March 1 1954 a 'very large thermonuclear device' was exploded at Bikini an atoll in the western Pacific. The resultant cloud of radioactive material drifted down wind and eventually settled over a cigar shaped area some 220 miles long and up to 40 miles wide. Instruments had been placed at intervals over the predicted area of fall out enabling the American scientists to measure the intensity of the radiation at different points and to calculate the number of casualties there would have been had the area been populated They estimated that up to 140 miles down wind from the explosion the radioactivity would have sufficed to threaten the lives of all unprotected persons who failed to take any precautions whatsoever, 160 miles down wind, about half the number of unprotected persons might have survived, while 220 miles or more down wind even those exposed to the radioactivity for as long as forty-eight hours would have stood a good chance of survival [33] In actual warfare the number of casualties could be much reduced by taking immediate cover and also by prompt decontamination even such simple measures as thoroughly bathing the exposed parts changing the clothing and avoiding the ingestion of contaminated food may often save life Nevertheless, the predictions gave some idea of what a single large bomb might do—at least to an unprepared and uninformed population

As everyone now knows partial confirmation of the scientists' calculations was not long in coming On the day of the test a Japanese fishing vessel, the *Fukuryu Maru*, had been operating within 100 miles of the explosion The crew of 23 saw the flash, and observed a column of white cloud rising rapidly into the sky About three hours later a white powdery ash began to fall on the boat and it continued to fall for several hours After a few days, the fishermen noticed that those parts of their skin which had been touched by the ash had become dark red and swollen and on their return to port a fortnight later the entire crew was found to be suffering from radiation sickness They were admitted to hospital where their progress was studied by members of the clinical division of the Japanese Research Council of Radiation Sickness.

33 United States Atomic Energy Commission The Effects of High Yield Nuclear Explosions. Feb. 15 1955

The initial symptoms were the same as those which had been observed among casualties at Nagasaki and Hiroshima Some of the men began to have headache, vomiting, and diarrhœa within a few hours of their exposure to the ash, and in many of them depilation started before their return to port In the first month, exhaustion and anorexia were prominent symptoms, some developed fever of up to 102°F, and others showed a mild hæmorrhagic tendency Radiation dermatitis was present in almost every case Blood examinations in all cases revealed greater or lesser degrees of leucopenia, erythropenia, and thrombopenia, and an increase in the coagulation time, in 5 of the men the leucocyte count fell within the first month to 1000 per c mm In August one of the men developed jaundice, and he died on Sept 23 Extensive studies on the spermatozoa of the other 22 men showed in all cases a gradual reduction in the spermatozoa count, a diminution in the motility, and an increase in the proportion of deformed spermatozoa By last December (nine months after the Bikini test) the spermatozoa count had in every case fallen to zero

No aspect of nuclear radiation is at present causing more concern than the harm it may do to future generations Clearly, the effect of exposure to doses of any magnitude is to produce a serious disturbance of spermatogenesis, possibly leading to sterility which, though not permanent, may last more than two years (as in some of the Hiroshima and Nagasaki victims) But the real hazard is of course far more serious Radioactivity of all kinds has been found to cause an increase in the mutation rate in all animals and plants in which it has been tested, and, since most mutations of genes are harmful, the result of irradiation is that after several generations the incidence of abnormalities is raised Geneticists are still uncertain of the threshold level of irradiation below which the mutation rate is not increased, and conceivably this may be only a little higher than that produced naturally by existing radioactive material in the soil, water, and air What is known, however, is that as a result of the 60 odd nuclear detonations to date, the total radiation received by the world's population has measurably increased[33], and each future explosion will raise the total still further The exposure of each American citizen has been calculated as having increased by an amount equivalent to that received during one chest radiograph (0 1r)[33], in this country, it is said, the corresponding figure would be about a third of this[34] The point at issue, however, is not what radiation is being received by the chest but what radiation is being received by the gonads The doses in question are, of course, far lower than those which radiologists working with radioactive materials consider dangerous, but it has already been argued that, since vast numbers of the world's population are at risk, the possibility that the genes of some individuals have already been damaged cannot wholly be ruled out Opinion differs widely and Mr Iain Macleod, speaking for the Government, stated last week that the increase in radioactivity to date is most unlikely to have had any appreciable genetic effect But the fact that the *recent white paper on defence did not even refer to the* subject does not suggest any great eagerness on the part of the Government to supply discouraging information

Clearly the evidence is far from complete, as regards both the effect of radiation on the present generation, and the possible effects on generations in the future But, whether or not the test explosions have yet done any permanent harm to the human race, it seems likely that their continuance will eventually do so, for Prof Joseph Rotblat[35] calculates that explosion of hydrogen bombs at the modest rate of 2½ per annum would in thirty years double the natural level of radiation As for full-scale warfare with these weapons, he says that "it is no longer a question of two nations, or groups nations, devastating each other, but of all the futu generations of all nations who will for ever pay, thro disease, malformation, and mental disability for o folly"

ELECTROCARDIOGRAPHIC CHANGES IN INFARCTION

THE electrocardiographic diagnosis of infarction still depends on recognition of abnormal patterns in th twelve conventional leads Attempts by vector analy to integrate the deflections of body surface leads into single expression of the electrical forces of the heart ha proved informative, but this method is too complicat for clinical practice Grant and Murray[1] have propo a method by which the surface of the chest is divid into areas of positivity and negativity, and a simp correlation is established between the cardiac vector a the deflections of the electrocardiogram The deflectio of precordial leads can be compared with those produc at the surface of a cylinder by an electrical dipole at centre, and will be at zero when the axis of the lead perpendicular to the cardiac vector By plotting a num of zero points for different instants of QRS (0 01 se *0 02–0 04 sec) Grant and Murray constructed "a n* contour" on the chest of healthy people, with a positi area anteriorly and to the left and an extensive negati or "Q" area to the right and posteriorly

They found that the essential feature of infarction conventional electrocardiograms was the encroachment the Q area for the first 0 04 sec of QRS on to the left a anterior part of the chest From an admittedly sm number of cases they concluded that the mean 0 04 s vector was abnormal when it was directed 45° aw from and posterior to the mean QRS vector, or, anatomical terms, when it was directed away from t left ventricle instead of from the mitral/aortic orifi Comparing the electrocardiograms of 180 cases, Gra and Murray determined the "infarct vector" by su tracting the post infarction from the pre-infarction v tor, and found that it was directed away from t damaged part of the electrical field deforming the fi *0 04 sec of the QRS complex in almost every case* Th located the electrical defect in the heart by this meth and found fairly close agreement with the conventio anatomical localisation Divergencies with diaphragma and anterolateral lesions were probably due to the dire tion of the pre infarction vector Two types of alterati of the terminal 0 02 sec vector of QRS were found—o in a direction opposite to that of the initial vector, a the other in the same direction There was evidence su gesting that peri infarction block without QRS prolong tion was responsible for the former, and complete tra mural electrical defect for the latter The field defect all these cases of infarction was on either the anterior the diaphragmatic surfaces of the left ventricle and w distributed along the line of the interventricular septu

Grant and Murray insist that the electrocardiogra records electrical rather than anatomical localisation myocardial damage, and that the agreement wi empirical anatomical localisation is incidental The fa that even with multiple infarction there is only one area proves, they think, that each lead records the su of all the electrical forces at its particular point on t body's surface rather than the potentials of the unde lying myocardium Prinzmetal and his associates,[2] the other hand, strongly support Wilson's "window concept of the QS waves in infarction, in dogs wi infarction produced by coronary artery ligation, the recorded identical QS waves from epicardial, intramur and cavity leads over areas of completely functionle muscle But that this is not the only explanation of t QS complex was suggested by the rather unexpecte finding of similar cardiograms, differing chiefly in dep and steepness of the QS wave from infarcts where there was both clinical and histological evidence of some muscle activity Seeking another explanation Prinzmetal and his associates recorded direct electrocardiograms from parts of the ventricle which had been progressively damaged by burning or excision When only subepicardial muscle was damaged R waves were still recorded but when the outer third of the ventricular wall or the deeper areas were involved R waves were replaced by QS waves These observations suggested that the subendocardial muscle probably because of its rapid depolarisation contributes nothing to the R wave in an epicardial lead, and that QS leads can be produced by subepicardial as well as by transmural infarction Prinzmetal and also Grant and Murray confirm the practical diagnostic importance of QS waves and Q waves of 0 04 sec as signs of infarction but seem to contradict each other on the theoretical aspect The difference may be explained by the use of direct leads by Prinzmetal and of body surface leads by Grant and Murray This work helps to explain some of the limitations of cardiographic diagnosis

THE GREAT SCHISM

For some years microbiological circles have been stirred by a debate on the function of the bacterial flagellum, between Prof A Pijper on the one side and almost all the world on the other [1] This heretic believes that, far from being the organ of locomotion the flagellum is a trailing appendage of an automotive cell; and his evidence is formidable Oddly enough throughout the argument little attention has been paid to the detailed structure of flagella apart from some pictures from the electron microscope which are more elegant that informative Now Leifson and his colleagues [2] have shown that in stained preparations the flagella of proteus have in the main two distinct and well defined shapes. What they call normal' is an open spiral (or zigzag) of two to three waves curly' is a tighter spiral (or zigzag) of four to six waves The two may be found on different flagella of the same bacterium and there are two rarer types Which type is seen is influenced to some extent by the environment in which the bacterium has grown The wave lengths of each type of curve are remarkably constant for the same species of bacterium Almost simultaneously Pijper [3] has published a note on the same subject based as always on observation of the living bacillus illuminated on the dark field by sunlight He confirms his original statement that as a general rule the bacterium advances by a spiral movement of its body with the flagellum sticking straight out behind like an otter's rudder (In the photographs this always seems a bit fuzzy) Under circumstances which he has not yet defined this straight tail shortens and assumes a spiral shape which may have one of two wave lengths one twice as long as the other Initially the change is reversible but in the end the organ always finishes as a helix or splits into fine helicules These may whirl about for a short time and thereby give some erratic movement to the bacterium (quite distinct in Pijper's view from true motility) but their development is associated with stiffening of the body and final immobility

A cautious view suggests that these two reports describe the same phenomena modified by differences in method If the development of Pijper's helicules is always associated with death or at any rate immobility it is not surprising that they should be the structures seen in stained preparations He says that they may appear to move to any part of the cell wall which would explain the lophotrichous and peritrichous arrangements so loved by the systematists What he does not mention is whether these helicules retain the wave length of the helix from which they derive Leifson has carefully measured the wave lengths of his two forms of curve, but does not call attention to what is clear from his figures—that the wave-length of 'normal" curves is always about twice that of 'curly" In comparing results obtained by methods so different it would be unfair to ask for complete agreement, but it is a fair guess that Leifson's flagella are Pijper's helicules. Is the fuzziness of Pijper's rod like flagellum due to its being made up of a sheaf of flagellella ? And is this the beginning of the end of the great schism ?

THE EVIL SPIRITS

Many distinguished bacteriologists and immunologists have talked optimistically of the problem of infectious diseases as virtually solved and in his presidential address to the American Association of Immunologists,[1] Dr T P Magill has taken these people to task

Like Dubos, whose latest book is reviewed on p 704, he draws attention to our anthropomorphic attitude of mind He points out that the peaceful bacterium, trying to find food and shelter in man is termed an aggressor, whereas it is just as reasonable to call man the aggressor and that many of the manifestations of disease arise only when man tries to exorcise these supposedly evil spirits This viewpoint has virtues not the least of which is its recognition that the aim of preventive medicine should be less to eliminate an infection than to attempt to come to terms with it Attempts at elimination may have been less strikingly successful than the decline in mortality rates suggests It is galling to have to admit that the rates for tuberculosis, diphtheria measles and pneumonia began to fall long before modern preventive measures could have taken effect A factor that is often neglected in calculations on trends of an infectious disease is its natural history or ecology There are many examples of diseases which have ravaged populations until in the course of time they have lost their malignant character Such a change may be due to any of several causes Huge numbers of susceptible people may have died leaving a resistant core and in the microbial population it is the less virulent organisms whose survival is favoured since the organisms which kill their host have entered a blind alley The recent myxomatosis epizootics in Australia and in this country have shown such processes There are likewise examples of diseases regaining their former severity

Magill's lecture will have failed in its purpose if it encourages any ideas of nihilism public-health measures immunisation and antitoxin therapy are indispensable The lesson to be learnt is that infectious diseases are far from conquered and that present methods of controlling them are far from perfect In our pride at how much knowledge of bacteriology and immunology has been gained we must beware of becoming too complacent about the evil spirits

FOOD POISONING

The Public Health Laboratory Service has published another of its valuable annual reports on food poisoning in England and Wales This report on the year 1953 [2] contains an immense amount of data much of which is given in tables and it lacks the dramatic impact of the same facts described in narrative form In 1953 there were 5277 incidents—an increase of 1759 over the previous year These incidents consisted of outbreaks family outbreaks and sporadic cases The increase is reflected in all the causes listed—namely staphylococci Clostridium welchii undiscovered and particularly salmonella Better reporting must be taken into account, but by the most optimistic estimate there has been no decrease in food poisoning The authors of this believe that at least 4000 cases were not notif is a very high proportion

As in previous years meat dishes particular or made up meat dishes were the most impor but ham and boiled bacon were particularly important as vehicles of staphylococcal food-poisoning Milk caused 12 outbreaks, of which 7 were associated with fresh milk, 4 with dried milk, and 1 with canned milk 3 of the fresh-milk outbreaks were caused by *Salmonella typhimurium*, 1 of these was due to infection of pasteurised milk during bottling, and another to unpasteurised tuberculin tested milk 2 of the fresh milk outbreaks were due to *Staphylococcus aureus*, originating from infected cows Several outbreaks were associated with sweetmeats, and one of these, known to have affected two people, was associated with vanilla slices "*S enteritidis var danysz* was isolated from the patients and from mice in the bakery concerned The bakery had been baited with *S enteritidis var danysz* to clear it of vermin a month earlier"

[1] Magill T P J Immunol 1955 74, 1
[2] Mon Bull Min Hlth Lab Serv 1955

The types of salmonella followed the same pattern as in previous years About 76% of cases were due to *S typhimurium* (aertrycke) with *S thompson*, *S enteritidis var jena* and *S bovis morbificans* next in order but accounting for only 7% of cases, the forty-six exogenous types accounted for 9% of cases *Cl welchii* food-poisoning was associated with meat dishes in every instance, except possibly 1 where the vehicle was not recorded

Fifty one deaths were recorded This report shows that food poisoning gives rise to a considerable amount of sickness with consequential loss of working time Much of this could be avoided by the education and co operation of the food handler We hope that the new Food Hygiene Advisory Council will accept as one of its first duties the education of the housewife, shopkeeper, restaurateur, and other food-handlers

CHIARI'S SYNDROME

THE clinical picture that results from occlusion of the hepatic veins is generally called after Chiari, who gave the first clear account of its pathogenesis[1], the disorder had first been reported by Lambron[2] some fifty years earlier From the number of published cases—115 by 1952—this syndrome might seem very rare, but this figure may be misleading, for Palmer[3] has reported 7 cases verified by necropsy and 4 presumptive cases all seen within a period of thirty-two months These cases were found at a large tumour clinic one of the commonest causes of the syndrome is encroachment by metastatic tumours on the hepatic veins, but since this is a late complication of malignant neoplastic disease it probably develops usually after the patient's discharge from hospital

The clinical features of the syndrome depend largely on the rate at which the hepatic veins are occluded In acute cases nausea, vomiting, and severe pain in the right hypochondrium due to rapid enlargement of the liver as a result of congestion may be quickly followed by death from hypotensive shock Less acute cases are characterised by severe and rapidly accumulating ascites and signs of portal hypertension with a developing collateral circulation Signs of hepatic failure are usually pronounced, and death results from hepatic coma Simultaneously developing œdema of the legs indicates involvement of the inferior vena cava in the occlusive process Chronic cases closely resemble hepatic cirrhosis, which may indeed develop as a result of the chronic liver injury due to the greatly impaired intrahepatic circulation Function tests invariably indicate severe parenchymal damage bromsulphalein excretion is much reduced, the serum albumin globulin ratio is reversed, and the flocculation test is almost invariably positive Patients rarely survive complete occlusion for more than a few months Ruptured œsophageal varices, portal or mesenteric thrombosis or intercurrent infection lead to death in the few who do n die of hepatic coma

Neoplastic involvement of the hepatic veins probab accounts for the majority of cases of Chiari's syndrom but occlusion of these veins or their ostia undoubte arises as a complication of many other conditio Palmer usefully classifies these under the follow headings congenital, mechanical, hæmatological, diffu and local liver disease, acquired vascular disease, an disease of neighbouring organs He lists some 42 c ditions as likely to be responsible for hepatic ven occlusion, of which 27 are known each to have accoun for one or more instances In patients severely ill w for example, leukæmia, cirrhosis, or local suppuratio chest or abdomen the syndrome may easily be overlook and even at necropsy the thrombosed hepatic veins easily missed if not specifically sought, and this r explain why published cases are so few

STRESS FACTOR IN THE DISC SYNDROME

WE may be on the threshold of important discove relating to the physiology and pathology of the in vertebral disc There is now evidence that the in vertebral disc is a hydraulic unit with a mechan generating an internal tension suited to the load impo on it The nucleus pulposus, exposed to isotonic saline, can generate considerable pressures (100–200 mm Hg) when resistance is offered to its swelling, and it is conceivable that an acute attack of lumbago might be due to disturbance of the mechanism controlling the access of fluid to the nucleus pulposus, with resulting tension—a possible parallel with the mechanism of acute glaucoma These speculations suggest possible explanations of the lumbago which follows exposure to cold and wet where there is no evidence of trauma

Scott[1] has described experimental evidence that swelling of the nucleus pulposus can be produced under the conditions of the "stress reaction" or "general adaptation syndrome"[2] The work reported by Scott was done on voles by D H Chitty, who exposed animals to strangers for about two hours a day for three or four days and then compared the size of the nucleus pulposus of each disc with that in control animals Statistical analysis showed that the difference between experimental and control animals was highly significant In support of the thesis that raised disc tension may be the basis of acute lumbago in man, Scott reproduces radiographs showing excessive hollowing of the opposing surfaces of vertebral bodies which enclose discs of rather more spherical shape than is commonly seen But many surgeons will regard this as a normal variation, commonly present without acute back pain, and in any case one would suppose it impossible for a vertebral body to adapt itself to a swollen disc in the three or four weeks during which the raised pressures of the acute tension episode are presumed to be present

We must here distinguish the difference in psychological states between patients with acute disc episodes and patients with chronic low-back pain Commonly, women who are depressed and unhappy subconsciously allow themselves to be disabled by pain of a degree which other women tolerate more or less easily Those who tolerate their discomfort do not tend to consult doctors, in other words, patients coming to hospital because of chronic backache are a self selected group On the other hand, in the case of really violent episodes of acute disc pain almost every patient seeks medical advice The experimental evidence of a "stress factor" relates essentially to acute disc episodes, but, though most surgeons would agree on the association of chronic backache with psychological disturbances, many will deny that this association is common in cases of acute disc lesions

MEDICAL ADVISORY MACHINERY OF REGIONAL HOSPITAL BOARDS

DOUGLAS HUBBLE
M.D Lond F.R.C.P

> I believe that a medical service cannot be effectively planned unless its organisation includes a comprehensive *and representative medical committee at regional hospital* board level This lack is one of the major defects of the present system. [1]

THESE words of the president of the Royal College of Physicians and the description of the effective machinery devised by the Liverpool Regional Hospital Board,[2] suggested that a survey of the methods used in other regions might be of interest

Of the 14 regional hospital boards in England and Wales 10 have a committee which whatever its title, corresponds in function to a medical advisory committee The constitution of these committees, their method of election and their method of reporting are set out in the accompanying table The organisation employed in the four other regions is as follows

Sheffield—The medical members of the board sit as the medical committee of the board Specialist advisory committees report to the board's medical committee Area consultant committees are consulted by and may advise the board

Birmingham.—A regional advisory committee composed of the chairmen of the group medical committees, sits to advise the senior administrative medical officer (S.A.M.O.) In addition there are advisory committees in each specialty

East Anglia—In each specialty there is an advisory committee to the S.A.M.O

North East Metropolitan.—22 advisory committees in the various specialties report through the S.A.M.O to the board Matters of general policy are referred where necessary to the advisory committee in general medicine

Thus the constitution of the medical advisory committees varies greatly, but most of the S.A.M.O.s express themselves as satisfied with their own organisation Although there are considerable geographical differences between the regions the methods of taking medical advice do not always seem to be the result of adaptation to environment There has however been at least one instance of evolutionary change in the South East Metropolitan region the medical advisory committee originally consisted only of the medical members of the board but it was later enlarged to make it more representative

In some regions the medical advisory machinery does not approximate to the ideal stated by Sir Russell Brain, and it does not always represent the clinical strength of the regional hospitals or of the medical schools. Even where a medical advisory committee is in being, it may not always be effective Sometimes its membership is too large and sometimes so small that it is unrepresenta

REGIONAL HOSPITAL BOARDS WITH MEDICAL ADVISORY COUNCILS

R.H.B.	No. of members	Including medical members R.H.B.	Description of other members	Method of appointment	Method of reporting	Frequency of meetings	Specialist advisory committees

2. Lloyd Hughes T *Ibid* 1954 ii, 617

tive of either areas or specialties. Occasionally it includes the chairman and vice-chairman of the regional board, which shows that its essential function has been misconceived. Sometimes its value is lessened by the infrequency of its meetings.

Granted that some form of medical advisory committee to each regional hospital board is desirable, its exact constitution may well be determined by local conditions. It should represent the active clinical life, not only of the regional hospitals but also of the medical school (or schools) in the region. It should include representatives of the more important specialties; but, since it is impossible to include them all, specialist advisory subcommittees will still be needed. It should include some, but possibly not all, of the medical members of the regional hospital board, so that its policy is understood and supported in the board. Appointment should be by nomination, supplemented by cooption. Nomination by regional consultants' or area advisory committees will permit of adequate areal representation; cooption will be required to ensure adequate representation of the important specialties.

I am grateful to the senior administrative medical officers to the regional hospital boards, who provided the information I have summarised.

A VISIT TO KOLTUSHI

The Study of Conditioned Reflexes

RUSCOE CLARKE
M.B.E., F.R.C.S.
SURGEON, BIRMINGHAM ACCIDENT HOSPITAL

LEONARD CROME
M.C., M.R.C.P.E.
NEUROPATHOLOGIST, THE FOUNTAIN HOSPITAL, LONDON

WE had visited hospitals and laboratories during the previous ten days in Moscow and Leningrad, and talked, notebook in hand, to many doctors, all anxious to explain. Sooner or later there would be that odd conversation, begun with some remark such as this: "during the last few years we have tried to base our work on the teaching of Ivan Petrovich Pavlov." In some of the hospitals they then showed us conditioned reflex laboratories for animals and for patients. In others they had departments for sleep therapy. And in all they attempted to interpret such familiar states as hypertension or peptic ulcer in terms of Pavlovian physiology.

A few of us had read some Russian journals and were familiar with this new outlook; to all others it was disturbing and elusive. One thing was certain: Russian doctors spoke of it with conviction and enthusiasm.

Now we were on our way to the premier centre of this new science—Pavlov's laboratories at Koltushi. This "Capital of Conditioned Reflexes" was constructed in 1929 in celebration of Pavlov's 80th birthday, and the new 28 laboratories were then linked with 6 other institutes in Leningrad itself and with several clinics.

Fifteen miles out of the city we turned off the main road into a quiet country lane and were soon entering one of the Koltushi laboratory buildings, the former home of Pavlov. Like all the other houses in the village it was two-storeyed and vaguely Tudor—out of place in the Russian countryside. Was it an idea owed Pavlov to one of his visits to this country? The avenues and flower beds lay al deserted in the half-hearted September sunlight.

In the absence of the director, Academician Bikov, w were received by his deputy, Academician Airapet'yan Surrounded by pictures and simple personal memen of the founder, we were first given a general outline o the work of the institute and of the principles of Pavlovia physiology. The objective of their study, we were tol was an understanding of the functioning of the organi in its unity with the environment.

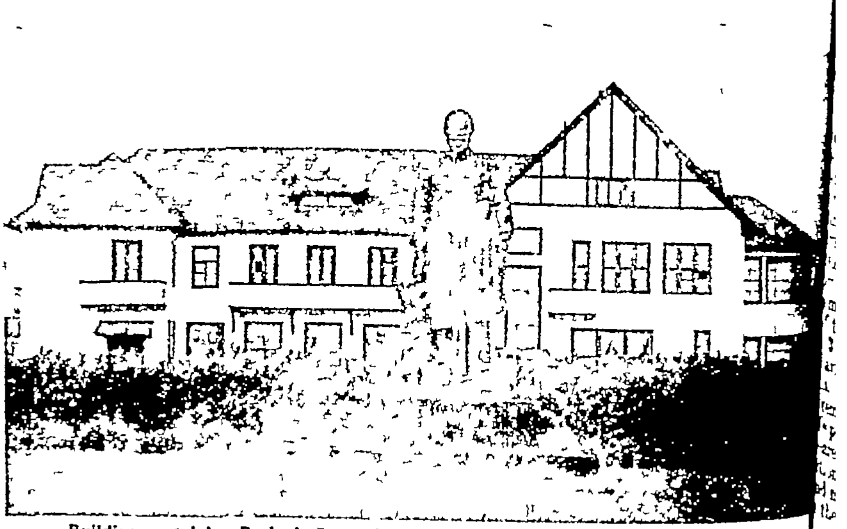
GENERAL PRINCIPLES

An animal, said our host, is in a state of consta interaction with its environment. Descartes knew alread that environmental factors determine the function of the organism by means of reflexes. Before Pavlov however, only inborn reflexes were studied. Man important discoveries had been made, especially by suc men as the great English physiologist Sherrington. B even Sherrington stopped short at the complexities o the brain, thinking that this was not amenable to stud by physiological methods. This domain was left t psychologists.

The way to a new approach was paved by the Russia physiologist Sechenov, whose *Reflexes of the Bra* appeared in 1862. Sechenov obtained experiment evidence that all the functions of the brain, includin mental activity, were also carried out by reflex actio But the question remained: How does it operate How is the interaction with the external environme achieved through the intervention of the brain? Pavlov great achievement was that he posed these questio correctly and discovered a new scientific method o investigation, objective rather than subjective, a metho that yielded more information than all the approache of the psychologists.

Pavlov found that, besides inborn reflexes, there ar others which arise from the individual experience of th animal. The basic inborn reactions may then be elicite in new ways and in new combinations by stimuli derive from the changing external environment. If any phenomenon capable of producing activity in a sensory pathwa immediately precedes, or coincides in time with, th operation of an inborn reflex, this new stimulus ca become capable of giving rise to the original inbor response. A dog is fed; a bell is rung at the same tim After a few combinations of the bell with the sight smell of food, the bell by itself calls forth salivation. An stimulus can act in this way and produce a reaction the animal.

How and where is the linkage formed? The answ was given by Pavlov not so much verbally as in thousand



Building containing Pavlov's flat and the Laboratory of Academician Airapet'yants of experiments Every stimulus capable of calling forth an unconditioned inborn reflex excites the unconditioned centres in the brain or lower parts of the nervous system at a level or levels determining the corresponding activity But every such excitation is also relayed to the cortex the highest and most recently acquired part of the brain Every external stimulus capable of giving rise to a conditioned reflex also excites the cerebral cortex—but somewhere else A state of excitation is in this way produced at the same or nearly the same time in two parts of the cortex and a linkage established between them This linkage is new and temporary but if repeated can become stable (Stable but not permanent This lack of permanence is a fundamental property of a conditioned reflex If the phenomenon which gave rise to it in the environment disappears or acquires a different meaning the conditioned reflex is altered or inhibited) Once it is established the unconditioned response can be obtained by excitation of the conditioned point of the cortex in the absence of the 'normal unconditioned stimulus A new reflex arc has been formed

These processes are precise, subject to laws, determined Thus any stimulus from the external environment if repeated in association with the stimulus appropriate to an inborn reflex can give rise to a new adaptive pattern of reaction These new reactions are formed in the cortex new conditioned reflexes allowing for the development of more intimately adaptive responses of the organism to the external environment Thus deciphered cortical activity can be defined as the processes involved in the relations between unconditioned and conditioned reflexes and also between the conditioned reflexes themselves In this way the animal becomes able to respond to an infinitely wider set of environmental agents than those which elicit inborn responses The concept is radical. There is nothing left of mental activity except complex relations between reflexes of one kind or another The mechanism of all mental activity is reflex Sechenov was right

Even such complex events as the whims of a child the romance of a girl the genius of Isaac Newton or of Garibaldi—all these are based on such reflexes Pavlov in his books *Twenty Years Experience* and the *Lectures on the Cerebral Hemispheres* gave precise experimental facts He founded a new science, a real science of behaviour the science of higher nervous activity Conscious and adaptive human behaviour depends on the activity of the cerebral cortex; but this activity is not only the mechanism of mental processes but also the dominant factor in the development of the individual

How are these processes localised in the central nervous system? Any approach to this question is based on three principles

1 No event can take place in the cerebral cortex without a cause immediate or distant in the environment There is no evidence for the occurrence of spontaneous cortical activity

2 Localisation must be related to the function of analysis and synthesis at the same time Pavlov demonstrated that the cortex may be regarded as a mosaic of analysers each of which has a centrally situated nucleus and very widely scattered peripheral elements. The finest analysis takes place only if the nucleus of an analyser is intact, while cruder analysis and much compensation for lost function after injury may be accomplished by the peripheral elements Synthesis—the formation of temporary linkages—cannot be localised to any one area of the cortex; it is taking place between all its parts

3 Localisation must be related to structure Here Pavlov opposed equally Lashley's theory of equipotentiality and the rigid mechanical concepts of localisation exemplified at present by the theories of John Fulton He preferred to think in terms of 'dynamic structures' areas concerned with a complex association of unconditioned and conditioned reflexes extending over variable and modifiable territory not only in the cortex but also in the subcortical centres He thought, in particular of the motor area of the cortex not as an effector organ for voluntary movement but as an analyser of kinaesthetic stimuli reaching it from all muscles of the body and in man especially from those in the hand and speech organs.

At Koltushi continued our guide, we have a great advantage in being able to undertake studies of the pathology of human disease alongside our experimental work on animals But the latter are essential for the knowledge of human activity A correct theory is essential and we believe that Pavlov's teaching provides the only correct theoretical approach to the study of functional relationships in animals and man It is vital for the clinicians who must learn that there is no such thing as disease in a single organ Every organ which is in any way diseased must in some way, to some degree affect the functions of the other organs and of the whole body The whole individual is ill, wherever the lesion is located the most important integration being achieved through the nervous system The central problem in medicine is concerned therefore with the functions of the nervous system with the elucidation of its laws of operation Naturally we do not exclude the study of other aspects of medicine and biology We attach importance to other forms of integration and interrelation, but we insist that the highest regulation of the animal is through the central nervous system and in higher animals, through the cerebral cortex

We asked if it was proved that the cortex alone was concerned with the formation of conditioned reflexes The answer was that where a cortex exists the highest regulation takes place at the cortical level but this does not mean that it can function without the lower levels of the brain and the nervous system It has been demonstrated that conditioned reflexes cannot be formed if the cortex is extirpated. Conditioned reflexes can however be formed in certain animals such as fishes, bees and silkworms, in which a cerebral cortex has never been developed In such animals it is the highest existing nervous ganglia which are concerned in the formation of conditioned reflexes

GENETICS OF HIGHER NERVOUS ACTIVITY

We then moved on to another building to meet Professor Feodorov and to hear and see a demonstration of his work on the inheritance of conditioned reflexes

Pavlov he said stated that conditioned reflexes must on a priori grounds be inheritable and become in the course of evolution inborn unconditioned reflexes During Pavlov's lifetime research had attempted to provide proof for this hypothesis but the experiments were not decisive and the results could be explained otherwise Recently work had been started again using mice because they could be rapidly taken through a number of generations A complicated piece of apparatus had been constructed wherein a mouse could be automatically released into a maze which if successfully negotiated led to a safe chamber The passages could be seen and the movements of the mouse recorded by means of a large wall mirror placed at an angle above the apparatus.

We sat and watched entranced the little white animals making their way with uncanny precision along the narrow corridors of this strangely fun fair like installation. The pathways were floored by a series of metal bars which could be electrified so that if the mouse remained too long en route to the safe chamber he would feel a continuous mild electric shock until the objective had been reached A bell or other neutral stimulus was set off and the mouse simultaneously released After six seconds the electric current was automatically switched in. After a few experiences of this arrangement a conditioned mouse would proceed straight to the safe cell on release and would avoid any shock at all.

The experiment could be made more complex by shining a light instead of ringing the bell and this time having the safe cell accessible only by a different route which made it necessary for the mouse to turn right instead of left if he were to reach the safe area before the current was switched on It was possible to continue conditioning experiments so that the mouse would choose the correct path when the left and right routes were alternately opened with the same stimulus Thus varying degrees of complexity in the conditioning process could be developed in a precise way

All the conditions of this experiment allowed for its operation without any intervention by the experimenter other than pre selection of the relation between the electric current, the pathway leading home, and the indifferent stimulus applied

With this technique a group of animals was divided into two groups, one a control The experimental group was trained to a given degree of complex conditioning and then allowed to breed as were the controls Each generation of the non controls was submitted to the same training process After a certain number of generations the controls were tested for their ability to acquire more rapidly conditioned reflexes necessary to avoid the electric shocks, and thus compared with similar mice whose parents had been trained

We were told that during the last few years this experiment had yielded decisive results, but that further experiments would be continued with a variety of other animals It was freely admitted here that what had been in fact acquired were not particular conditioned reflexes but the capacity to form them in conditions of a persistent change in the environment calling for these reflexes

These experiments are reminiscent, of course, of the work of McDougall and of Tryon and appeared to us to be of fundamental importance It is with great interest that one awaits their publication and repetition elsewhere This work is, incidentally, to be associated with studies of the minute structure of the brains of these animals, in an attempt to gain evidence of structural change associated with this evolutionary process which is thus being achieved in the laboratory

COMPARATIVE PHYSIOLOGY

We moved on through the trees to the next laboratory for a demonstration of work on the comparative physiology of higher nervous activity

The problem here was adaptation of young animals Previously, we were told, many of the adaptation processes had been regarded as entirely dependent on the active rôle of the mother, with the young animal behaving more or less passively It "contemplated" but did not adapt This conception was considered improbable on theoretical grounds, but the problem of demonstrating the acquisition of conditioned reflexes in the newborn animal was difficult technically Pavlov's salivation techniques were inapplicable and new methods had to be developed to suit different species of animals

Experiments with puppies showed that conditioned reflexes could be formed in relation to the sense of smell immediately after birth

Two days before parturition the bitch was specially cleansed and treated with a scent Puppies taken away at birth would respond by withdrawal on presentation of a piece of cloth steeped in the scent But after one experience of suckling, for even as little as five seconds, they would subsequently, when hungry, crawl towards the scented cloth, whining and behaving as they would normally towards their mother With a different smell the response was totally negative, they turned their heads away and crawled back Even premature animals showed this capacity for acquiring conditioned reflexes and were quite helpless if deprived of this capacity by division of the olfactory pathway They were then unable to suckle when put to their mother and would starve unless given a great deal of assistance in feeding

The first important analyser in the life of a puppy is that of smell

By the fourth day puppies respond to adequate auditory stimuli, and by the fifteenth day conditioned es can be established to sound

A bitch is kept in one cage, the puppies in another bitch is allowed to visit the puppies, but this is accom by sound After two or three combinations of sounds the mother's visit the puppies will respond to sound as if the mother were approaching

Similar types of experiment using the visual analy showed that conditioned reflexes could be established 25–30 days Further experiments studied the estab ment of conditioned reflexes through the vestib apparatus

Birth took place in a box on springs the vibrations of wh could be recorded The puppies could be conditioned to re to any movement of the box as to their mother's approa If born in a non moving box puppies would not respond such movement These conditioned reflexes could be obtain by the twelfth day

Further experiments of this kind were concerned w the problem of types of higher nervous activity Pavlo detailed studies of the reactions of animals had led h to appreciate the significance of differences in t response of different animals to attempts to indu conditioned reflexes He found among his animals do with strong nervous systems and with weak ones T strong ones could be further subdivided into balanc (phlegmatic) and non balanced (choleric) From t viewpoint of the mobility of the nervous processes t strong balanced animals could be either mobile (sangui or inert It will be seen that this classification resembl the Hippocratic one of human temperaments, the we dogs suggesting the melancholic temperament Expe ments have been now pursued in this laboratory with t object of creating and changing such types

Experiments were begun as soon as the dog could leave mother Some were given the maximum free contact w their environment, others of the same litters were to so extent isolated These changes were associated with delib ately varied diets Different types of higher nervous activ could be deliberately produced in this way, and, in early sta of life, changed in a desired direction In fully grown do it has been found, the basic properties of the nervous syst are almost impossible to change, though existing quali can be enhanced or moderated

The experimental production of types has been link with the study of the emergence of the various sens analysers A current experiment was dealing with relation between *subliminal* painful stimuli and effects of stimulation of the auditory analysers

Litters of puppies were divided into three groups C group was fed while rattles were sounded, a second group subjected to the rattles plus subliminal painful elect stimuli, a third acted as controls This was continued six months with careful observation of behaviour during t period The puppies in the second group developed slowly passive defensive reaction behaving as though they we frightened The first group and the controls developed such reaction

After six months they were all given Pavlovian saliva fistulas so that their salivary secretion could be used as indicator of the production of conditioned reflexes The do which had been subjected to the rattles plus the pain stimuli formed no conditioned reflexes, their cortex seem to be in a permanent state of negative induction—inhibit The dogs subjected to the rattle treatment only were str and highly reactive—more so, indeed, than the controls. addition, the inhibited animals did not grow well and beca bald *Attempts were made subsequently to cure them* by complete change of environment In some of them this co be done, but others remained permanently abnormal.

Another point of interest in relation to the rea of the organism to infection was that it had been that a leucocytosis could be produced as a cond reflex

BIOCHEMISTRY

In another laboratory we discussed the contri biochemistry to the Koltushi research on condit flexes. Pavlov had envisaged that in course of time he complexities of the brain structure—its microscopic orphology—would be related to the processes under ing the formation and interaction of conditioned flexes and that biochemistry would throw light on the molecular nature of the processes involved in nervous ctivity Biochemical research had, however, lagged ehind

An approach was now being made to the basic processes underlying cerebral activity Already it had merged, for example, that the cortical processes of the og and the rabbit are biochemically very different gain, whereas it was previously thought that the white matter of the brain, consisting largely of connecting bres is essentially passive in a functional sense, it has een found that biochemically the white matter is often more active than the grey The task is to extend our iological knowledge of nervous processes and particuarly of those underlying the development and interaction f conditioned reflexes in the cortex Histochemical methods were showing for example, that the distribution f nucleic acid in the nerve-cells differed with different unctional states—with excitation and inhibition, both onditioned and unconditioned

CORTICO VISCERAL RELATIONSHIP

Regretting the absence of a biochemist amongst us, e proceeded to the next laboratory—of Academician irapet'yants, our host and guide He wished to tell us omething of the studies on cortico visceral relationships n which he had been working with Academician Bikov ut thought we had had a long morning and were perhaps ired We asked him how long he would take to tell us f the work. He said that it could be done perhaps, in three hours, or three days or three weeks, or three years ut he would tell us a little in twenty minutes and then here would be time for questions. We agreed

Bikov was one of Pavlov's pupils and has been engaged n this work for the last twenty years It was necessary o show experimentally that the cerebral cortex really ontrols without exception all functions of the body, nd that conditioned reflexes can be developed in connection with all functions of the organism It has in fact een possible to establish conditioned reflexes using a arge variety of bodily functions—secretion of bile, ecretion of urine, intestinal peristalsis, and vascular eactions All reactions which can appear as a result of ppropriate stimuli as unconditioned reflexes can be voked by any indifferent stimulus which coincides in ime

Ingestion of a lot of water will result in diuresis. If his drinking is accompanied by the ringing of a bell hen later the bell alone will evoke diuresis Excitation preads along a cortical path which has now been established and the kidney is brought into operation If such hings can happen in ordinary life they can also happen under pathological conditions Pathological processes an never take place without involving in some way the erebral cortex The pathological state of an organ does ot necessarily originate in the cortex although it may o so but the cortex always plays a part in the development or arrest of any pathological processes

What is important here is to take the argument a stage urther If the cortex controls and regulates internal organs is it in its turn influenced by them ? If we can orm conditioned reflexes to external stimuli, can conditioned reflexes be likewise formed by 'indifferent " stimuli arising within the body ? To answer these questions has been the particular task of Airapet'yants s boratory

Let us take for example a dog with a gastric and a livary fistula You introduce some water or a balloon to the stomach carefully so as not to affect other sense gans No saliva will be produced from the salivary fistula Now you combine gentle gastric dilatation with feeding After a few combinations the gastric dilatation alone will stimulate the flow of saliva A full stomach has begun to stimulate appetite !

From this and similar experiments with other organs it is concluded that the stimulation of any organ, of threshold intensity, leads to excitation of the cortex. If this is accompanied by excitation of another cortical area by a stimulus derived from another organ there is, as with external stimuli, a linkage a conditioned reflex can be established The cortex is capable of responding to stimuli from all somatic organs and viscera—mechanical chemical and physical—by analysis and synthesis, by the development of conditioned reflexes It can react to degrees of temperature, concentration of chemical substances and chemical differences As with the external environment so all reactions of the internal environment operate through reflexes and these too include conditioned reflexes All this should not be interpreted, however, in the sense that processes in organs can be primary ' or ' spontaneous They do not occur without a cause in the environment, either immediate or more remote

This we were told is not only of importance to theory and to philosophy but also to clinical medicine. On a-priori grounds it may be assumed that the human organism like that of animals operates through such reflexes but it is also necessary to observe this in man We need proof and detailed understanding of the mechanisms The operation of the brain is, moreover more complex in man because he possesses a second signalling system (The discovery that words operate as conditioned signals of a second order was one of the most remarkable chapters in the work of Pavlov Towards the end of his life he came to grips with one of the most mysterious problems of cerebral function—the nature of human thought He found that it was intimately related to speech This in its turn was mediated by conditioned reflexes of a more complex character constituting an additional signalling system capable of greater adaptability to a much wider range of environmental influences —making possible indeed such processes as ' abstract thought ')

In the final stages of our visit we discussed some clinical experiments which showed that changes in visceral function can be produced by previously indifferent stimuli bringing into action special associations which have been formed with words and figures In patients with peptic ulcer for instance, contractions of the stomach are associated with sensation of pain By a process of conditioning, the figures on a clock could be made to produce both contraction of the stomach and the pains of an ulcer Thus we were shown something of the experimental basis for sleep therapy in certain diseases one of the effects of which is to exclude the harmful action of a whole range of environmental stimuli which have become associated with pathological processes

CONCLUSION

It was time to leave We wandered out into the open and looked at the growing village with its new laboratories and homes for those who work in the laboratories We saw some special rooms for the more complicated experiments on dogs and apes. They are designed to eliminate accidental features and the impact of the observer on the experiment (We had seen on other occasions how fond the physiologists were of playing happily with their experimental animals " after hours ") The rooms are elaborate and sound proof Mechanical contrivances present the dog with a plate of food on the pressing of a button Innumerable controls operate a wide range of stimuli Special recording devices register changes in the secretion of the saliva and of other visceral functions There were other simpler fixtures designed for use in any laboratory undertaking work on conditioned reflexes

We shook hands and exchanged compliments Half an hour later we were threading our way cautiously past ruts and pot holes in the as yet unfinished streets of the advancing Leningrad outskirts It was three or four hours that we spent at Koltushi, and we had no more than a glimpse of the new science Was it a glimpse into the future ?

PREVENTION AND MENTAL HEALTH

Conference of the National Association for Mental Health

OPINIONS differ about the possibility, in the present state of our knowledge, of preventing mental ill health , but there is a general feeling abroad that in time research will bring enlightenment about this and many other aspects of mental health work At this year's annual conference of the National Association for Mental Health, held at the London County Hall on March 24–25, with Mr KENNETH ROBINSON, M P, presiding, Mr IAIN MACLEOD, the Minister of Health, opened the first session

OPPORTUNITIES IN THE HEALTH AND EDUCATION SERVICES

Mr MACLEOD spoke of the fears and prejudices about mental illness which still hinder both the use made of the mental hospitals and the recruitment of nurses General practitioners and voluntary workers, who can do much to educate the public, should be well informed about recent advances in the mental field Mental hospitals are arranging open days and forming leagues of friends , and the press and the British Broadcasting Corporation are helping greatly in spreading information Probably all mental disorders are of multiple origin, but it seems clear that in their prevention we must go back to old wisdom recognising that lack of love, lack of companionship, and lack of security are potent causes of breakdown There are now 650 outpatient clinics in the country for adults and children who need treatment On the preventive side, local authorities have the power to provide community services , but though they undertake various types of work which may be called preventive, they have been slow in developing a formal pattern Their opportunities for preventive work among children—through the health visitors and the maternity and child-welfare clinics—are very great Health visitors, indeed, are taking an increasing interest in the subject , and a working party is now considering how their training should be revised and widened He had, he said, asked the local authorities, last November, to do all they could to prevent the break up of families Once a child leaves school he has no routine public health supervision , hence it is important that his family doctor should be in full touch with local authority services, so that he can call on them when necessary It is not yet possible to advise local authorities, by circular, on what mental health services they ought to provide, but they are being urged to take a keen interest in this work Public education will gain momentum as patients and their relatives get a new awareness of mental hospitals and their services Mental hospital buildings are expanding under the new programme and with better buildings we can look forward to attracting more recruits to nursing

Dr F A E CREW, F R S , professor of public health and social medicine in Edinburgh University, said that medical knowledge has so far contributed little to the prevention of mental illness He sees no real hope of a speedy solution to this problem, but thinks that social, as opposed to individual, studies provide some clues

A Chicago survey of mental hospital patients suggests that not only mental illness but social factors such as poverty, crime and suicide, are related to a particular factor—namely, 'isolation' This finding is supported by experience York, that mental illness is commoner among immigrants than among the native born population among the children of immigrants than among native- children The newcomers, until they are absorbed fully the new culture, are lonely and isolated A study, in London boroughs, has shown a negative correlation of su with poverty, but a positive correlation with loneli Other investigations, in Massachusetts and in Norway, h shown that the chances of admission to mental hospital greater for the unmarried, widowed, or divorced, particul men, than for the married Either those who marry, Prof Crew said, are less liable to mental illness than those remain single, or else marriage is protective He ment also a study, not yet published, made in Edinburgh Dr Donald Cameron, of the places of origin of mental hos patients He found that the admission rate of those the Highlands and from foreign countries (which did include England and Wales) was higher than that of Edinburgh born , and that among the patients the s were twice as numerous as the married

Such findings, Professor Crew went on, cannot be f interpreted without more study What is marriage? this country a reasonable prerequisite for the foun of a family, that microcosm in which children mature , an opportunity for emotional and se security , and also, in the lovely phrase of the Pr Book, "for the mutual society, help and comfort the one ought have of the other" The married pe is no longer alone but a member of a group with b of affection, and with a place of his own and thing his own—a refuge This may determine whether or he goes into a mental hospital, and if he does how he stays there Our society has produced condit which are to a greater or less extent intolerable there are many bewildered and perplexed people wit a purpose During the war the mental health of country was surprisingly good the lonely were res —there was a place and function for all The ca of mental ill health are partly individual and pa environmental , and while it is desirable to plan f society in which causes of mental ill health are remo we need to know much more before we can create a society At present we can only attempt to stem torrent

The rise in the admission rate to mental hospita not trustworthy evidence of an increase in me ill health, because patients are now going in volunta hopefully, for treatment But the incidence may rising, and that may be either because our stoc deteriorating or because the circumstances of life inc ingly provoke mental illness We must find out wh We cannot be mistaken, however, in attempting remove those provoking causes which we know important for mental health that the individual sh be attached to a faith, a cause, a purpose, which gi serenity We talk of mental health without know what we are talking about , but if it is peace wit and peace within the environment, it is perhaps a ma of philosophy rather than the ticking of a mach What a man does should be within his competence value, and regarded as valuable by others He m not feel he is an outcast but a part of a group , must take into marriage an understanding of what involves, and know something of his own sexual natu (For the young person, Professor Crew remarked passing, a motor bike is no substitute for a cage of m

During the war, the Navy and the Royal Air Fo had the more intelligent recruits , the Army got all t dull, the neurotic, and the unstable It is no lon true that the dull man makes the best soldier he ne today, average intelligence and not a little techn skill The duller men in the Army were apt to bec maladjusted and neurotic absentees In the Pion Corps, however, there were some men too intelligent to have been sent there, and they too became neuro they benefited by being given more responsible No man should be employed in work either above low his mental capacity Doctors, instead of signing rtificates saying a man is not fit for his job should rhaps start signing some which say 'Job not fit r man We are dedicated Professor Crew concluded the creation of an environment optimal for human This is a cause which can claim our unrestrained otion and one from which we can hope to derive ding joy

RACTICAL PROBLEMS IN LOCAL AUTHORITY SERVICES

In opening what the CHAIRMAN described as a rumbles session Dr J L BURN, medical officer of lth for Salford offered as his first grumble the lack recognition of the importance of mental health in al authority schemes. They spend far less on it than their other health services and place too much phasis on the mental hospital and too little on the me 'Only when other public health resources (such rehousing) fail he said do we think of mental re' and this is an expensive way of arriving at a agnosis. Many opportunities of preventing ill health uld be taken with little expenditure The antenatal nics could be used more freely *for teaching the club* ea could be extended group therapy *encouraged some* mily doctors might be persuaded to send patients rlier for treatment, hostels could be provided for mental fectives, and educationally subnormal children (who ovide a high proportion of delinquents) could be pervised for three years after leaving school The eak up of a family often dates from their eviction for n payment of rent: there are no statutory funds to de them over such a crisis (though health visitors often nd what is necessary out of their own pockets) He rged the need for 'more bridges'—such as case nferences between hospital and local authority staffs efore a patient leaves a mental hospital

MISS E STEPHENSON chief nursing officer at Newcastle pon Tyne as a nurse midwife and health visitor, has ood opportunities for observing the barriers our services uild up between each other (Some of them, she said re themselves suffering from mental ill health they eed to foster good family relationships within their ome departments) In the home the family doctor the ealth visitor the midwife and the district nurse are ll preventing mental ill health by being good listeners is part of the health visitor's job in addition to teach ood living but she needs to know when to call in an pert and to have an expert at hand to call in She o since she knows the family ought to be invited to tend case-conferences.

Miss S FRIEDMANN educational psychologist to the ity of Oxford regretted that local authorities have so *ttle sense* of urgency about mental health work They ould never dream she said of appointing one dentist r one afternoon a week to look after the teeth of a opulation of 10 000 children but they often appoint ly one psychiatrist to such a population—though ental growing pains are just as common as toothache he child guidance clinics have enormous waiting lists ad children may wait a few weeks or a few years for eatment—which should be given early and neither late *or* as a last resort

Mrs. M ORMEROD chairman of the joint Bethlem oyal and Maudsley Hospital board of governors and ember of the London County Council health committee id that the grumbling of the experts had fairly and uarely exposed the faults of the local authorities She she said, a reasonably good mother but whenever she terviews a nicely dressed woman with two clean and eely dressed children and learns that they and the ther are living in one room—eating sleeping and doing e family washing in it—she wonders what sort of *mess* e would have made of a like job Something can be ne by education committees and fortunately Lon ners like spending money on education She thinks that every penny spent on child guidance and on classes for the educationally subnormal child is well invested helping to prevent both mental ill health and crime But housing of course is a more difficult matter She spoke of the closer coöperation of the psychiatrist and the family doctor which has been achieved in Amsterdam The Maudsley Hospital she said *is hoping to start a* domiciliary service with a view to keeping more patients in their own homes for treatment We have some glimmer of how to make people secure we know security is based on happy family life Sir Geoffrey Vickers[1] has described the most important promise of mental science as that of "helping us to conceive of mental health as a positive dynamic condition of mind to see the path towards it to develop the will to achieve it' "We members of local authorities' Mrs Ormerod said must develop the will to achieve it

PROMOTING MENTAL HEALTH IN A LOCAL COMMUNITY

Dr S A MACKEITH consultant psychiatrist to a group of Norfolk hospitals pointed out that local authorities are desperately short of psychiatrists and psychiatric workers, whereas regional hospital boards though they have not enough of these workers do nevertheless employ considerable numbers of them He suggested that the boards should permit and indeed encourage their psychiatrists to devote one session a week of their time to mental health work for a local *authority—not* in fresh treatment clinics but in preventive mental health fields found by experience to be fruitful, He himself had asked the medical officer of health of a local *authority* to allow him to work for one session a week in a maternity and child welfare clinic where he hopes to learn in time how to spot at an early stage the over anxious or otherwise disturbed mother who will be *bringing her child* to a child guidance clinic in 5–10 years time An experienced psychiatrist working part *time for a local* authority might help in various ways—by holding discussion sessions for midwives and health visitors attending meetings of the medical officers employed by the authority, and acting as psychiatric adviser to the M O H and psychiatric catalyst to the medical work *of the* local authority generally The training of duly authorised officers he thinks should be weighted on the social rather than the psychiatric side but *nevertheless* they should have some training in psychiatric case work This should be given by psychiatric *social* workers, who like the regional board s psychiatrists should be encouraged to give a little time each week to the local authorities. They should be asked especially, *to advise* at reception-observation centres for children

He mentioned the Amsterdam scheme,[2] in which the psychiatrist, before recommending any treatment interviews the patient in his own home Other experiments deserving wider study are the day hospital and the night hospital (from which patients go out to work) Psychiatrists might also help local authorities by advising on the appropriate treatment of old people with mental disorders. We are still too ill informed about prevention to be dogmatic but one important thing is to respect the point of view of the other *fellow* Let us not rush to tell other people how wrong they are in what they are doing' He believes in supporting the *authority* of the family and increasing its self-confidence—particularly the self-confidence of the young mother in her *feelings* and impulses toward her child. Whatever we do growing up from infancy will always be a strenuous and frustrating business adolescence a stormy time and no *amount* of tactfully given information about the facts of life will alter that Perhaps good mental health like good morale in an army unit cannot be achieved by direct means perhaps it is he said "the bloom on the fruit of a really sound society"

In England Now

A Running Commentary by Peripatetic Correspondents

ONCE in the days of our master, the Commander of the Faithful, Haroun El Rashid, on him be peace, in the season of the ripened dates, there came two wise men riding from the west And after they had shaken off the dust of the plains they sought the ear of the Caliph But Abu Newas, his wazir, stopped them at the gate of the City of Peace and said What manner of news do you bring from the Land of the Free? And the first wise man said Lo, we bear a magic potion for your maidens and your young men, that they may smile upon each other with pearls as white as asses' milk in the moonlight That your wives shall not spit their teeth into the dust when they are heavy with child That your aged ones shall not chatter false mouthings in the market place And Abu Newas was glad in his heart, for he found joy in both the comeliness of maidens and the flesh of a roasted sheep

So the wise men were led into the presence of the Caliph And Haroun El Rashid heard their say And Abu Newas whispered Give them a thousand dinars, O master, for they worship gold in their land, and let us have neither holes in our teeth nor pains in the night But the Commander of the Faithful said Stay! I would first know how this magic potion, which you call Fluor, shall be given to my people And the first wise man replied It shall be poured into every well in your kingdom, that all must partake of the blessings of mankind But Haroun doubted and said How shall I know that it will not harm my people if they drink too much? And the second wise man replied Their teeth will become mottled as the camel's and their backs as stiff as rocks, but see, we have a thousand scrolls in our caravan to bear witness to the wisdom of our wise men And Abu Newas whispered Their people worship a god called Science only a little less than gold Let us test their magic on thirty-six of our children And Haroun said Let it be so

But many moons passed, and Abu Newas had to slip with the cunning of a jackal through the time of Questions Some of the thirty and six children were changed by magic into men and women, and the scrolls were lost in the secret registry And Abu Newas cried three times that the wise men of the west must be wiser than any tests But the Commander of the Faithful was beleaguered by his wives, who made much song and dance, and said It is against the will of Allah to medicate the masses It is not justice to make your people of all ages drink this Fluor when even the wise men say its magic spell works feebly after eight summers have passed away And yet other zealots trailed strange western fish called herrings across the palace yard And the Commander of the Faithful held his head and groaned Bring me a goatskin of wine, and cast this noisy mob into the river that they may take their fill of water And cast Abu Newas and the wise men in as well, so that once more I may rule over the City of Peace Let it be so

* * *

It's the nights that get me down A typical night in our family goes like this Midnight, I've just got warm and am dropping off when banshee wailing from Second Child recalls me. I get up, find my slippers and dressing-gown, and stagger down the arctic stairs to get him a drink (warm orange, in pink mug—no other acceptable) and deal with his other metabolic needs Then, cursing roundly, I tuck him up and go back to bed, to find my husband hogging my warm patch and snoring heavily A few sharp kicks right this, and I settle down and am deliciously warm and sleepy when agonising howls from Third Child break out. Same procedure as before She is starving and soaking I apply her drink (warm milk in a red mug) to the appropriate end and dry towelling to the other, fling her back in her cot, and stamp off to bed again This time I manage to snatch a little sleep, and it is 3 A.M. before First Child has a nightmare, and eldritch screams of "Mummy, Mummy—there's a fire engine in my bed!" be dealt with (He has cold blackcurrant in a blue mug) The cat is now in my warm place
the morning my husband asks brightly, "Well—w
sort of a night did you have ?"

Professor A decided to telephone Professor B to
they could go to a committee meeting together Pro
A is a busy man and he cannot be expected to hold on
a telephone line while the nurses look for Professor
So he has a secretary to whom he says "Get me
fessor B on the phone" Professor B is equally busy
he cannot be expected to answer the telephone himsel
or to hold the line while someone's secretary says "W
you hold the line, Professor A would like to talk to you
So Professor B also has a secretary who answers h
telephone and puts through his calls

When Professor A's secretary asked Professor B
secretary if Professor A could speak to Professor
Professor B's secretary felt some alarm It appea
that on a previous occasion when Professor A h
telephoned Professor B, Professor B's secretary had go
to a great deal of trouble to find Professor B, who w
in the middle of a ward round at the time with some
or 20 lesser beings following him Unfortunately wh
he got to the telephone Professor A's secretary w
unable to find Professor A With great presence of mi
she had said that Professor A had been called aw
suddenly, but Professor B did not believe this st
—and indeed he was quite right, since Professor A w
known to be rather forgetful and had actually gone
to the laboratory to look at some kymograph tracin
Professor B's secretary therefore produced a gene
solution to all problems of this nature, she simp
announced that Professor B was engaged at the mom
and that he would telephone Professor A when
was free

Those who have the gift of seeing general princip
behind the ordinary details of everyday life will at o
grasp the fact that this story shows up a fundamen
problem which we might call "the law of telepho
precedence" Stated as simply as possible it imp
that a great man shall not be made to give way t
lesser man in answering telephone calls One difficu
remains—that of establishing rules for settling pr
dence And here I think we are entitled to some h
from the National Health Service Many secreta
lacking in experience would be greatly helped if they
some system of finding out a man's importance quic
What about a simple scoring system? 10 marks
a consultant or a professor, 8 for an F R C P, 6 for

dexamphetamine are living on the fat of the land?

Letters to the Editor

MUSCULAR DYSTROPHY

SIR,—The Central Council for the Care of Cripples has decided to form a Group or Association of patients suffering from Muscular Dystrophy, and has already found that there is considerable interest in such a development, particularly among the patients and their parents. Numerically the problem is not a large one but the people concerned are often isolated and it is the Central Council's intention to establish a friendly link, to provide interest and amusement for the children and to distribute leaflets of general information to parents, members and others.

It is beyond dispute that research is of paramount importance and your readers will agree we feel, that there can be no firmer basis on which to develop the work which is contemplated than through the advice and support of the many distinguished neurologists and other specialists who have accepted appointment to the Medical Advisory Committee which the Council has set up.

The chief difficulty from the Central Council's point of view as a voluntary society is to find the people it wishes to help. Nevertheless ascertainment of the extent of the problem is an essential if real progress is to be made. I am therefore writing to ask anyone in sympathy with this movement to put their patients or others known to them in touch with the Central Council for the Care of Cripples. I must emphasise that the Group will remain within the ægis of the Council which intends to use its existing County Associations rather than to superimpose a new organisation.

Central Council for the Care of Cripples

HALLUCINOGENIC DRUGS

SIR,—We hope you will allow us to voice a word of warning regarding the use of the so-called 'hallucinogenic' drugs, notably lysergic acid diethylamide (LSD 25). Although its application especially as an adjuvant to psychotherapy is suggested by recent work[1,2] we feel that too little as yet is known about individual differences in susceptibility to warrant its use except under closest supervision. Our own observations in normal volunteers, and reliable reports from colleagues suggest that:

1. During acute intoxication the subject may potentially be a danger to himself and to others.
2. In single instances a delayed and exceptionally severe response may take place and be followed by serious after-effects lasting several days.
3. Early psychotic conditions may be aggravated by the drug.

Until more is known about its mode of action, we urge those interested to refrain from using the drug in out-patients or in day hospital patients and restrict its use to inpatients—and then only when constant supervision by trained personnel is available. At this early stage it seems to us wise to tread cautiously and to protect what may be a promising new method from indiscriminate use and untimely haste.

BURNS FROM ELECTRIC BLANKET

SIR,—An unusual domestic hazard which may face young children was recently illustrated in my practice.

A 4-year-old boy was sleeping in his parents' bed, in which an electric blanket had been placed beneath the lower sheet. The heat control had previously been set to the minimum. The mother found the child unconscious and rigid; the father in attempting to rouse him received a not inconsiderable electric shock from the boy's body. The blanket having been disconnected the sheet was found to be saturated with urine and the child had suffered full-thickness burns of the skin of his back, buttocks and thighs. He rapidly recovered consciousness and was admitted as an emergency to the nearest hospital. Subsequently he was transferred to a pædiatric burns unit.

Since the use of electric blankets is becoming increasingly widespread both in homes and in hospitals, the dangers of their use by infants, young children and enuretics should surely be stressed. Moreover it should be incumbent on manufacturers to make provision for adequate earthing and preferably to fit an automatic cut-out to counter an accidental short circuit.

London, N.11

NEVILLE DAVIS

JOURNEY'S END

SIR,—A year ago in an article entitled 'African Journey'[1] I recorded some impressions of a trip from Cape Town to Cairo during which I visited the main medical centres in the Union of South Africa, Southern Rhodesia, British East Africa and the Sudan. From evidence obtained at many clinicopathological conferences I came to the conclusion that certain diseases, which cause a vast amount of ill health in Europeans are much rarer in Africans. They fall into two main groups:

(1) Diseases which are commonly called 'psychosomatic' by those who believe that emotional factors are of major ætiological importance—e.g., peptic ulcer, essential hypertension, rheumatoid arthritis, and toxic goitre.

(2) Diseases which may be caused by metabolic factors—e.g., atheroma and its sequelæ (cerebral thrombosis, coronary thrombosis, and peripheral vascular disease), cholecystitis and gall-stones, and diabetes.

This difference in prevalence could be attributable to racial and constitutional factors or to environmental factors such as diet, housing, and associated infections. In concluding my article I suggested that if the diseases which are commoner in Europeans than in Africans are due to environment rather than race their prevalence should be conspicuously higher among those Africans who have adopted Western customs, eat Western food, and are submitted to the emotional strains of modern civilisation. To complete my African Journey therefore, I went last December to the Southern States of the United States of America so as to obtain information about the prevalence of these diseases in the American Negro.

When I previously visited South Carolina and Georgia thirty-two years ago the economic, social, and educational state of the vast majority of coloured people was exceedingly poor. Malnutrition was rampant, housing conditions were usually deplorable, and the daily wage was often as low as 50–75 cents. Two world wars and the industrialisation of the Southern States which has resulted from them have led to a revolution in the living conditions of the Negro.

Alike in the factory and in the field he receives the same rate of pay as his white neighbour (perhaps 6–12 dollars a day). A Negro woman doing domestic work is paid 6 dollars a day. Negro boys and girls go to well-constructed primary and secondary schools and many proceed thereafter to college. The average coloured family lives in a house which, though the general standard has greatly improved, would still be considered unsatisfactory by white people of the same economic class; but with less to pay in rent and taxes for his house the Negro may have more money than a white workman, *on the same weekly wage*, to spend on food, drink, tobacco, motor cars, and other luxuries.

Standing in a main street in Charleston, South Carolina, ~~one evening I watched the stream of cars which carried the~~

workers back to their homes in the suburbs and in the surrounding country There appeared to be more cars driven by coloured people than by white people, while the condition, make, and size of the cars seemed to be the same in the two group

In one generation the material prosperity of the American Negro has been transformed, and at the same time malnutrition and deficiency diseases (such as pellagra) have virtually disappeared, malaria has been eradicated, and many diseases such as enteric fever and dysentery, which are associated with bad hygienic conditions, have been greatly reduced On the other hand, material prosperity does seem to have been bought at a considerable price, for everyone with whom I discussed this matter told me that the psychosomatic and metabolic diseases have much increased among the Negro population of the United States Dr V P Sydenstricker, professor of medicine in the University of Georgia, informed me that whereas at the beginning of his professional career forty years ago these diseases were rare among Negroes, they are now very common Several distinguished physicians told me, indeed, that Negroes are now developing malignant hypertension and the collagen disorders more severely and at an earlier age than white people

The evidence before us leaves little doubt that the origin of many diseases is closely related to the working and living conditions and eating habits of Western civilisation The relative importance of metabolic and emotional factors in the ætiology of these diseases remains to be ascertained We are also left with the question whether people who have once enjoyed the material pleasures of modern times will ever be willing to return to a simple agrarian life

Edinburgh STANLEY DAVIDSON

INVESTIGATION OF METABOLIC DISORDERS

SIR,—My colleagues and I are investigating the population genetics of three rather rare metabolic disorders pentosuria, cystinuria, and alkaptonuria We should be very grateful if general practitioners and consultants could put us in touch with patients known to have any of these disorders

Department of Biochemistry
London Hospital Medical College,
Turner Street, London E 1 H HARRIS

AIR EMBOLISM

SIR,—Dr Snell (March 19) rightly says that lowering the head as a first aid measure may be life saving in this emergency and adds, but does not stress, "preferably with rotation to the left side" He speaks of "pleural shock" and "obstetric shock" together as if, when due to air embolism, they were of the same kind, whereas the former is arterial and the latter (primarily) venous

In arterial air embolism such as may cause "pleural shock" in artificial pneumothorax therapy, air can reach the brain and cause many, often transient, symptoms, but it can also enter the right coronary artery and kill the patient quickly In the left lateral position the uppermost part of the beginning of the aorta will be the part without a coronary orifice, and therefore in this position the risk of coronary air embolism should be lessened It would be interesting to know on which side the patient was lying in cases of death from air embolism complicating artificial pneumothorax therapy

There are two reasons why in venous air embolism also the left lateral position is important (1) arterial (coronary) air embolism may complicate entry of air into a vein paradoxically because of a patent foramen ovale, (2) venous air embolism causes froth in the right ventricle but there is experimental evidence that this is less likely to block the outflow tract when the body is in the left lateral position[1]

No one doctor can speak from great experience of embolism, and when he meets this emergency and decided what to do it may be too late I think th artificial pneumothorax therapy, intravenous th and indeed in any procedure which might be compli by this or any other accident the doctor should, b starting, give thought to what might go wrong and w he would do if it did First-aid measures in air em should include turning the patient on to his left side *addition to withdrawing the needle (if any) and lowering* the head

Chase Farm Hospital,
Enfield, Middlesex C ALLAN BIRCH

FIBRO-ADENOSIS

SIR,—I have been expecting someone to comment your annotation of Jan 1 Under the heading of Fib adenosis it gave a brief summary of an investigat by Dr Kiaer on the potential dangers of (accordi to a footnote) fibro adenomatosis or chronic mastit The confused nomenclature makes it difficult to ass the value of any investigation

"Fibro adenosis" as a comprehensive title was sug gested by Atkins to include a number of structu changes in mammary tissue "Fibro adenomatosis," surely, is mostly a male affair, and covers the majori of enlargements of the male breast from childhood t old age The terms "chronic mastitis" and "chro cystic mastitis," inaccurate but harmless, originated fro the writings of Astley-Cooper (1828), Benjamin Brod (1840 and 1860), and Paul Reclus (1868) to become eve tually—in the opinion of Foote and Stewart—little mo than conditioned reflexes of the surgical mind.

At a later dater date Schimmelbusch (1892), Bloodgo (1923), and Cheatle and Cutler (1931)—who all, incide tally, combined the rôles of surgeon and histologist were mainly responsible for raising doubt on the inte pretation of one phase or histological pattern of "chro mastitis" still often referred to as Schimmelbusc disease This state of mammary tissue has been persisten regarded by histologists as pathological, depicting, effect, neoplasia of non functional tissue

For their impressions of a lump in the breast clinici are largely dependent on abnormalities of the grou substance, and, when histologists threw doubts i their minds about epitheliosis, microcystic hyperpla and other microscopic findings, something of a grievan was developed and gradually displaced on to lum breasts in general This misunderstanding bet clinicians and histologists—who often, so to speak, l far apart—brought "chronic mastitis" under suspi and was responsible for innumerable mastectomies, at any age, more especially during the 1920s and '30

The very nature of this subject, dating presumab from the emergence of the primates, does not permit clear cut clinical and histological divisions, nor for t matter of a satisfactory comprehensive title No unif standard of structure and function applies to ma tissue rather has it "a wide variation from time time and from individual to individual without in any other organ in the mammalian body" (Creigh Most of the common structural changes, however, roughly into two groups with a subdivision of second

1 Exaggerated physiological changes

2 Pathological changes Neoplasia { non-invasive / invasive and irreversible

In an important article[1] E K Dawson enters a that the terms "adenosis" and "fibrosing adenosis" hypertrophy of functional tissue during adolescence, adult life, with a pregnancy-lactation period, or regression from fertility—should be maintained escribe the first group Adenosis in this sense is neither disease nor a menace

---

[1] T M, Long, J, Oppenheimer, M J *Amer Heart J* 269

[1] *Edinb med J* 1954, 61, 391

On the other hand, once a neoplasia is established, its estimation may be earmarked biologically, from the tart; yet histological confirmation one way or the other ay on occasion be near impossible A variety of physio gical and pathological patterns may be found in sections om different areas of the same breast These are often terpreted as stepping stones to disaster, but presum bly could be tissue reactions to a varying chemical tatus

London, W 1 — F D SANER.

PNEUMOCONIOSIS

SIR,—Dr Triger[1] has commented on the lack of com arisons of pneumoconiosis diagnoses during life with ost mortem findings, and Dr Fletcher[2] has subsequently rawn attention to the observer error in pathological sessment

This problem of comparing diagnoses intra vitam with st-mortem findings in silicosis has been repeatedly idied in Germany

> Worth and Nerroter[3] have analysed the data for 327 cases silicosis confirmed by necropsy The degree of silicosis was sed on the older classification into stages I II and III In 83% of the cases there was agreement between clinical d post-mortem findings for the degree of silicosis found king the necropsy findings as correct, the clinical results erestimated the disease in 8% of the cases and under timated it in another 8% The overestimates occurred iefly in stages 0–II and the underestimates in stage III.

Although the German classification is not appropriate r pneumoconiosis in coalminers and differs from the assification used in this country, a detailed survey ere would probably also show reasonable general agree ent between radiographic and pathological observations.

RUPTURE OF DUODENAL STUMP AFTER GASTRECTOMY

SIR,—Mr Henson's paper (March 19) draws attention n afferent loop obstruction as a dangerous complication f a Polya partial gastrectomy The successful result his case emphasises the importance of his early and ccurate diagnosis of this complication which is gradually ecoming more widely recognised

With regard to his conclusions I would suggest that, n addition to careful clinical and radiological examina ions the gastric remnant should always be aspirated ith a Ryle's tube, when afferent loop obstruction is uspected Absence of bile in the aspirations will confirm hat the afferent loop is obstructed This simple test an be performed in a few minutes in the ward and may ive useful results particularly at times when the clinical igns are indefinite and radiological facilities are not mmediately available

Ilford Essex. — R P WARREN

SIR,—I was interested to read Mr Henson's article lthough I am not sure that a distended afferent loop er se will cause the blowing of a duodenal stump I feel hat it may contribute to this catastrophe With an nperfect duodenal suture line afferent-loop distension ould conceivably hasten the breakdown of the closure nd add to the violence of the burst

For four years I have been performing a Roux-en Y nastomosis in the Polya type of gastrectomy for odenal ulcer This operation results in deviation of e afferent loop from the gastro intestinal anastomosis d is undertaken to prevent the post gastrectomy syndrome We stated that a point incidental to the Roux en Y type of anastomosis was that the duodenal contents pass uninterrupted into the jejunum thus diminishing the risk of a blown duodenal stump[1]

My experience with the Roux-en Y anastomosis has been that, while a small number of minor duodenal leaks have been encountered (about the seventh day with little inconvenience to the patient), there have been no cases of catastrophic burst duodenal stump This may prove an important advantage My experience supports the claim that a distended afferent loop is an important factor in rupture of a duodenal stump

J EWART SCHOFIELD

PERFORATED DUODENAL ULCER AND SLEEPING POSITION

SIR,—Few will dispute that hyperchlorhydria is an important factor in duodenal ulceration The following investigation was suggested by the possibility that gastric and duodenal night secretions, collecting at the most dependent portion of that part of the gut, might there cause ulceration The most dependent portion will of course vary with the patient's position, but changes of position are very much less at night and so it seemed reasonable to expect some relationship between sleeping posture and the site of ulceration

One obvious objection is that the lie of the stomach is very variable for this reason gastric ulceration was ignored throughout the investigation. The position of the duodenum is also variable but the differences are comparatively slight. The anterior surface of the first part of the duodenum nearly always passes transversely from left to right with a slight tilt superiorly and posteriorly The digestive juices of the patient who sleeps on his belly will therefore bathe the anterior wall of his duodenum; and the juices of the patient who sleeps on his back will (though to a lesser extent because of the posterior tilt) bathe the posterior duodenal wall

This hypothesis may be criticised on the grounds that the gut is not a flaccid gutter that its walls are normally in apposition and that stagnant puddles of secretion are therefore unlikely to form. Yet at laparotomy the duodenum is usually found to be uncollapsed and peristalsis is less noticeable there than elsewhere in the small gut More difficult to counter is the suggestion that people do not know in what position they sleep—they know only the position in which they fall asleep During the night, if advertisements are to be believed vast amounts of energy are expended in twisting and turning Nevertheless careful observations on sleeping hospital patients reveal that major movements involving complete change of posture are made on the average some three or four times only and usually the patients revert quite soon to their favourite sleeping position Most patients become more restless towards morning but quite a number—particularly women—lie log like all night in one position

Sleeping posture varies considerably with age the young sleep more often on their bellies than do the old and more older people—perhaps because of fat bellies and less adaptable vertebral columns—sleep on their backs. Nevertheless, the most common position in all age groups is on the right side Slightly less common are those who sleep on their left sides Comparatively few persons sleep on their backs, and even fewer sleep on their bellies

100 patients who had had anteriorly perforated duodenal ulcers (confirmed at laparotomy) were first investigated. Those who had returned home were sent a questionnaire concerning their position during sleep, and the others were questioned verbally Many were unable to make dogmatic statements so the words always,' usually sometimes," and "never' were used in estimating the frequency of the four positions (right side left side back, or belly) When allowances had been made for intermediate positions, the findings were as follows:—

Chiefly on the right side	45%
Chiefly on the left side	33%
Chiefly on the belly	None
Chiefly on the back	22%

The average age of these patients was 48

[1] Triger K. Lancet 1954 i, 74
[2] Fletcher, C. M. Ibid p 648.
[3] Worth G Nerroter W Beitr SilikForsch 1954 30 3

[1] Schofield J E. Anderson P St. G Brit med J 1953, ii 595.

137 outpatients and inpatients also of an average age of 45, but with no recognised abdominal troubles, were then similarly questioned, and the following results obtained

Chiefly on the right side	44 %
Chiefly on the left side	35 %
Chiefly on the belly	9 %
Chiefly on the back	12 %

Contrary to expectations, the results showed that patients who had suffered anterior perforations slept less often on their bellies than those in the control group There are two possible explanations for this the duodenal contents may be satisfactorily buffered, even in those with hyperchlorhydria, by the duodenum's own alkaline secretion and by the lessened nocturnal biliary and pancreatic contributions, a more probable explanation is that patients with anterior duodenal ulcers find that lying prone is more uncomfortable than lying supine 2 patients spontaneously admitted that, shortly before perforating, they had found that their pain was very much less if they turned on to their backs

My thanks are due to Mr Richard Charles and Mr Arthur Hill for permission to interrogate their patients

Ipswich EDWARD ELMHIRST

ARTIFICIAL POSITIVE-PRESSURE RESPIRATION

SIR,—When respiratory paralysis is associated with pharyngeal paralysis special precautions must be taken regarding artificial respiration Brown et al [1] emphasised the need for early tracheotomy, thereafter artificial respiration may be applied by means of a tank respirator [3] or by intermittent positive pressure (I P P) through a short cuffed endotracheal tube inserted directly into the trachea [3,4]

While some I P P machines are designed to intermit the flow from a cylinder of compressed air or mixture of oxygen and nitrogen,[5,6] many others are designed to pump room air rhythmically from a bellows [7,8], and with these a pressure operated (P O) inspiratory/expiratory valve must be used This type of valve is used in the positive pressure attachments with which many tank respirators are now being fitted [9] In prolonged I P P with a bellows type machine, the air passes through breathing tubes and a humidifier to the P O valve, then through a short piece of wide bore rubber tubing to a suction connection attached to the cuffed endotracheal tube The P O valve is of crucial importance, for it must respond promptly to the rhythmic alternation of inspiratory and expiratory pressures in the tubes, must seal accurately in either phase, must offer minimum airflow resistance (especially to expiration), must never stick, must be robust, and must be easily cleaned and sterilised

The P O valve described here was designed by one of us (G T S C)

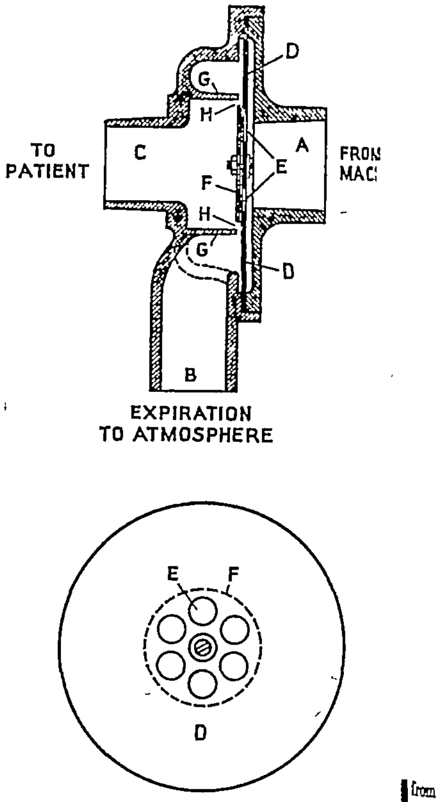

Fig 2—Above, diagram of the valve. Be diaphragm showing inspiration ports and p valves (interrupted line)

The valve (figs 1 and 2) consists of an aluminium casing with three ports—inspiratory (A), expiratory (B), and inspiratory/expiratory (C)—and a diaphrag (D) of reinforced rubber The casing is made in two par which are held together by hinged clips similar to those us on the distributor head of a car When assembled, the casi firmly grips the margin of the diaphragm The diaphrag has a ring of six air holes (E) and carries a thin central attached metal plate (F) and two studs which fit into corre ponding notches in the casing to ensure correct positionin With the diaphragm in neutral position a gap of 1/32 in sepa ates it from a circular sealing rim (G) which surrounds t inner aspect of the inspiratory/expiratory port By undo the clips and opening the casing the diaphragm may removed and a fresh one installed in a few seconds diaphragm and casing withstand sterilisation by boiling

On inspiration air is forced through the six air h simultaneously pushing the diaphragm against the rim and the metal plate away from the air holes expiration the diaphragm breaks away from the sealing and returns to its neutral position, impelled by suction the expanding bellows on one side and by pressure from recoiling lungs on the other and aided by its own elasticity The same forces seal the metal plate against air holes, compelling the expired air to pass through single expiratory vent (to which a spirometer may be atta when desired)

The combined area of the air holes and the area enc by the sealing rim determine the resistance of the valve airflow—which is up to 10 cm water pressure in inspi (varying with the condition of the diaphragm) and 2 water pressure in expiration The 1/2 in excursion (H) of diaphragm from the neutral position is crucial in val efficiency

The casing offers no lodgment for water condensing the expired air, provided the expiratory vent is downwards to allow drainage No sliding parts that stick or wear are used in the construction of the valve

Careful watching and frequent changing is necessary in use of any P O valve and a spare valve must always be hand The valve described here should be changed at daily, although it has been found to function effectively few days without attention, occasionally it may be suffic to change the diaphragm only The application of neg

ressure in expiration ("blow and suck") is advocated by aloney et al[18] but with a P.O. valve of this type suction ould interfere with closure in the expiratory position. In ny case, "blow and suck" action is not possible with the pparatus used at present in Britain. Future models will mploy mechanically operated valves rather than P.O. valves; he former will operate effectively in either I.P.P. or "blow nd suck" respiration, and will entirely remove the fear of alve failu[illegible]ould.

PPARATUS FOR TESTING POSITIVE PRESSURE EQUIPMENT

In assessing the efficiency of new apparatus it is ecessary to measure function against a standard. ccordingly one of us (G. T. S. C.) constructed a testing achine for I.P.P. equipment (fig. 3) in which a oncertina bellows acts as an artificial lung.

The relation (if any) of the expansile response of a patient's ung to the expansion of the bellows is not known, but the ellows works within the range of expected clinical pressures y expanding against a spring which, at a tidal volume of 20 ml., produces a pressure of 10 cm. of water. The expansion f the bellows is communicated through a simple lever system o a ball point pen moving to and fro along parallel guides. he mounting allows the pen to rest solely by gravity on graph aper, which is unrolled by clockwork at a constant speed. seconds recorder (also with ball point pen) works off an lectric-clock mechanism. A gauge indicates the pressure in centimetres of water) inside the bellows.

The inlet port of the machine will take a P.O. valve direct—orresponding to "mask" conditions—or will accommodate lastic tubes of two sizes, representing the male and female rachea respectively, into which cuffed endotracheal tubes an be inserted as in clinical practice in I.P.P.

The aim throughout has been to eliminate friction and erkiness, and so abolish adventitious movements of the ecording pen; the resultant curves are smooth and free rom unexplained fluctuations. They relate directly to ositive pressure and volume, but not to negative pressure, hough the latter shows on the curve and can also be read n the gauge. The device gives constant results under the ame conditions and thus can function as a reasonable standard. It has been indispensable in developing the P.O. valve described above and has been used to compare the performance of a number of such valves and of I.P.P. machines. The tester may also be used to measure the effect on airflow resistance of varying the other components of an I.P.P. assembly—e.g., the size of endotracheal tube.

HYPERGLYCÆMIA AFTER BURNS

SIR,—It is some time since I discussed the occurrence of hyperglycæmia and glycosuria after burning injury with Dr. J. P. Bull and his colleagues at the M.R.C. Burns Unit in Birmingham. I was therefore very interested to read in Dr. Sevitt's letter (March 12) that he has found additional evidence of adrenocortical overactivity and also changes in the islets of Langerhans at post-mortem examination in such a case. Dr. Sevitt has misunderstood me in stating I suggested that early involvement of the islet cells did not take place. He is correct in presuming that the reducing substance in the urine of my patients was glucose, not lactose or galactose; *incidentally none of my patients were* treated with lactose powder. Finally, I described the effect of a single dimercaprol injection on glucose tolerance in the burned cases as slight. However, to my colleagues and me the implication of this, coupled with the more pronounced effects after several injections in some diabetics, is that replenishing or augmenting SH groups may alleviate faulty glucose metabolism in certain patients.

EFFECTIVE CIRCULATION OF UTERINE WALL IN LATE PREGNANCY

SIR,—Dr. Schuurmans (March 26) in accounting for the efficiency of anti-histamine treatment in pregnancy toxæmia has advanced hypotheses which much evidence refutes.

He assumes that permeability of the maternal capillaries exists in pre-eclampsia to account for the œdema. This cannot be the case, for the protein in œdema fluid amounts to 0·10–0·48 g. per 100 ml.—a level insufficient to overcome the osmotic pressure and attract fluid out of the vessel wall.[1–4]

Nor can adrenaline or noradrenaline be invoked in the causation of hypertension, for it has been shown by Assali[5] that benzodioxane effective in producing adrenergic blockade was without effect on the blood-pressure in normal or toxæmic pregnancy. Corticoids, too, cannot be of primary ætiological significance,[6] since their function appears to be regulatory. Further, the level of the lipid-soluble substance in the urine, a reflection of the corticoid content of the blood, does not correspond with the severity of the toxæmic state,[7] and therefore is not consonant with the ætiological importance of corticoids—*a fact confirmed by the failure to provoke* toxæmia in pregnancies other than the first. Contrary also to Dr. Schuurmans's contention, evidence has accumulated in recent years to show that histaminase activity is unchanged[8] or is even considerably reduced in pre-eclamptic toxæmia.[9,10]

*There would, however, appear to be another explana*tion for the therapeutic effect of anti-histamines, based on their effect in overcoming renal spasm. Chatterjee[11] has administered these substances in resistant cases of

anuria, the sequel of severe cholera, with remarkable success Here the only possible explanation for their effectiveness was that they overcame the basic renal ischæmia responsible for the renal failure It would be reasonable to conclude that Dr Schuurmans's success is similarly explained; for I have shown[6] that such a renal state, provoked by the resistance to stretch of the myometrium, underlies the toxæmic process

THE PSYCHIATRIC DAY-HOSPITAL

SIR,—In your annotation of Feb 26 the reference to the paper from Bristol on this subject should read, not Aron, K W, but Aron, K W, and Smith, S The Bristol day hospital experiment was initiated, and is still being conducted, under the general supervision of Dr Smith

Ayr K W ARON

INFECTION WITH CRYPTOCOCCUS NEOFORMANS

SIR,—In the absence from this country of Dr Beck, and as the one associated with him in case 1 of our article (March 12), may I reply to Dr Michaels (March 19)?

I think that he is interpreting too rigidly the phrase "revealed the true nature of the illness" He will no doubt have noticed that in our discussion we referred to the *association* between cryptococcosis and Hodgkin like lesions, and that we had also considered that in these cases the explanation might lie in an alteration of certain immunity mechanisms However, the statistics of the series we cited suggested that the explanation may not be quite so simple as that and it was this thought we had in mind.

I have had the opportunity of seeing a section of a lymphatic gland which showed cryptococci in typical Hodgkin tissue, this gland had been removed in the early stages of generalised lymphadenopathy

In our case 1 the cryptococci were present in large numbers in the sample of cerebrospinal fluid taken on admission before any antibiotics had been given. I believe, too, that Dr Michaels will find that a large proportion of the cases in the series reviewed by the authors we mentioned occurred before the days of antibiotics

I M TUCK

B C G VACCINATION

SIR,—Dr Webster (March 5) asks very pertinent questions regarding this prophylactic measure and quotes Prof Heaf (Feb 12) "statistical proof is difficult to obtain" May I give my views on some of these points in the light of tuberculin-sensitivity surveys of the school children in Lewis in 1949 and 1954 and the administration of B C G vaccine

I was extremely keen on pressing on with administering B C G to every tuberculin negative person—young or old—whom I could discover, because of the exceptionally high mortality rate (1948, 176 per 100,000, 1954, 76) and the sustained high notification rate with 50% of all notified cases yielding positive sputum, and the abnormally high infection rate among school entrants (5–6 years) of 18% A high positive reactor rate in this group must surely imply many infectious cases in the population, and a falling off of this rate likewise must indicate a diminution of these Such a fall was observed on a second tuberculin sensitivity survey in 1954, when the rate was down to 2 7% for entrants In view of this I concluded that there did not seem the same need to push B C G The death rate fell to about 12 per 100,000 in 1954

This glorious result could not be attributed to B C G—it was a natural fall consequent on improved social conditions and better treatment of infectious cases However, closer study of the figures (March 19, p 620) suggested that the higher the positive reactor rate in any area the lower the mortality, seeming to indicate that immunity is related to allergy Again allergy as produced by B C G appears to give enh[illegible] resistance By September, 1954, of 3000 vaccinated (the majority three or four years previously) none had [illegible] notified as tuberculous whereas of 1188 positive reactors 1949 29 had been notified, and of 2814 negatives 9 had [illegible] likewise notified, and since September, 1954, several positive and negative reactors have been [illegible] requiring sanatorium treatment In view of [illegible] once again instituted a vigorous B C G campa[illegible]

With regard to unpleasant consequenc[illegible] have only 3 cases of axillary adenitis with absce[illegible] because the long time necessary for healing of the [illegible] have gone in for vaccination by multiple pu[illegible]cture after concentrating the vaccine as supplied, by [illegible]ntrifuging and discarding 50–80% of the supernatant liquid (I a[illegible] endeavouring to find the most suitable concentration) The subsequent local reaction, which appears in fro[illegible] seven days onwards, is slight, has had no undesirab[illegible] side effects, there is no ulceration or scarring, and th[illegible] skin over the vaccination area simply desquamates I[illegible] 50 cases so vaccinated the "take" has been 100%, an[illegible] the conversion rate has been 100% also The conversio[illegible] time is much shorter than by intradermal injection Th[illegible] perfection of this technique would mean enormou[illegible] advantages and would allow mass B C G vaccination t[illegible] be undertaken with ease by school medical officers an[illegible] general practitioners With Heaf multiple punctu[illegible] apparatus a single test only is necessary Where loca[illegible] authorities provide segregation homes the short[illegible] conversion time would mean a considerable saving Fo[illegible] this multiple puncture technique I would suggest that [illegible] suitably concentrated vaccine should be put up in sing[illegible] doses in capillary tubes as is done with calf-lymph

Dr Loxton (March 19) mentions desensitisation b[illegible] artificial means I have scores of children reverting t[illegible] negative (to 100 T U) naturally, and over a score wh[illegible] showed radiological evidence of infection and yet hav[illegible] lost their hypersensitivity to 100 T U When B C G w[illegible] administered to some of these they once again becam[illegible] positive Again, some B C G reverters after three yea[illegible] were revaccinated by multiple puncture, and the loc[illegible] and allergic reaction appeared simultaneously in less th[illegible] seven days How does this fit in with Godlowski'[illegible] enzymatic hypothesis?

I am convinced that B C G confers immunity of a hig[illegible] degree No special precautions regarding segregatio[illegible] were taken here, and the majority of vaccinated childre[illegible] live in the areas with the high sputum-positive rat[illegible] should like to see all babies given B C G at birth

Stornoway, Lewis R STEVENSON DOIG

THE ACTION OF CHLORPROMAZINE

SIR,—I have read Dr Buxton Hopkin's accou[illegible] (March 19) of the French work dealing with the so calle[illegible] "phenomena of Reilly" with bewilderment

> These effects, we are told, follow "irritation as oppo[illegible] to either simple section or stimulation of sympathetic nerves"[illegible] they are produced by "perisplanchnic injections of differe[illegible] substances," and, "physical agents—e g, trauma an[illegible] electrical stimulation." The condition is rapidly fatal and [illegible] accompanied by widespread lesions, including hæmorrha[illegible] and necrosis of the suprarenal glands as a constant featur[illegible] The "irritation" of the splanchnic nerves produces co[illegible]spicuous changes in the cerebral circulation. "Pathogen[illegible] impulses" pass from the brain to the periphery "Th[illegible] effects are produced by placing irritants in direct cont[illegible] with or in close proximity to autonomic nerves in amou[illegible] which would be innocuous by injection elsewhere"

The results described are so strange and unexpecte[illegible] and the explanations offered are so much at varian[illegible] with current physiological thought that I for one pref[illegible] to suspend judgment until this experimental work ha[illegible] been repeated and confirmed by reputable worke[illegible] elsewhere

Department of Physiology,
Middlesex Hospital Medical School,
London W 1
SAMSON WRIGHT

MASKED EPILEPSY

SIR,—Some children have periodic attacks of headache, or abdominal pain, or vomiting or limb pains or fever, and these five symptoms may be grouped together as the recurrent syndrome Dr Wallis (Jan 8) suggests that many perhaps all of these children may have epilepsy I agree with Professor Illingworth (March 26) that it would indeed be a tragedy if all of this large group of children were deemed to be epileptics, and I doubt very much whether it is true From clinical experience I am satisfied that each of the five symptoms can be the bodily *manifestation of a tension state* and the common factor to them all is tension Recurrent abdominal pain in children, for example, fulfils the criteria of a stress disorder,[1] and it usually clears up after measures have been applied to relieve the tension Giving phenobarbitone, which Dr Wallis recommends, is one such measure, but this is a palliative treatment only Thorough treatment involves exploration of the child's mental state and his home environment, this takes time but the time is well spent because after treatment the child and his mother are better adapted to their lives and more content

London W 1 DESMOND O'NEILL.

SIR,—When a new idea appears one can either disbelieve it or try it out I have heard of a famous surgeon who was wont to raise a laugh in the operating theatre by saying "Close the door sister; we don't want one of Mr Lister's germs to creep in" The laugh is now (to mix metaphors) on the other foot

Professor Illingworth prefers disbelief to experiment, but the letter, in the same issue from Dr Ulutin, shows that experiment is more rewarding I will not attempt to answer all the points raised by Professor Illingworth Most of them have been dealt with in my paper

For instance he says that attacks of fever are not manifestations of epilepsy whereas in my description of case 2 I showed that the child was in hospital suffering from an unrelated disease and the attacks of fever and vomiting were observed by competent clinicians but could not be explained He has also neglected the experience of Davidson and Lombroso which I cited.

I should, however like to comment on three-month colic.

Professor Illingworth says I can see not the slightest connection or resemblance between three-month colic and epilepsy After reading his exhaustive paper on the subject[2] one is driven to the conclusion that no-one knows the cause of this malady But there are several clues to its nature: first the experience of Sir Frederic Still and Dr W Sheldon, cited by Professor Illingworth, that in some cases the condition leads on to convulsions; second the comment[3] that the disease is apt to run in families and may be linked with a particular kind of temperament; third the experience of Dr Millichap who states (Feb 19) that some of his patients with cyclical vomiting had had colic in infancy

I can think of four ways in which this hypothesis might be tested first to inquire into the family history of those children who suffer from three-month colic; second to take electro-encephalograms from them; third, to try the effect of *anticonvulsant drugs* and *fourth, to follow them into later life* and see if they do develop convulsions. The first three methods have not been tried as far as I know Until Professor Illingworth has used them I must consider his dogmatism unjustified The fourth seems promising in view of the work of Still, Sheldon and Millichap

As to the mode of onset I know that Sir William Gowers liked to hear of a sudden onset before making a diagnosis of epilepsy But, as someone has written he spoke without benefit of electro-encephalography No doubt he would now be the first to admit that the sort of cases he described in *The Borderland of Epilepsy* should really be included within the limits of that disorder

Some may think that we are arguing about something that does not matter—i.e., a name. I feel very strongly that it is important that these conditions should be recognised and *treated*. Children still die from cyclical vomiting[4] Now that the nature of the condition is known there is no excuse for this to happen

Professor Illingworth complains that hospitals will be inundated with requests to investigate obscure pains, vomiting and fevers. Surely the more such cases that are investigated the better

Bath. HUGH R E WALLIS.

STERILISATION OF SYRINGES

SIR,—About five years ago I gave up wrapping syringes in lint or gauze before boiling them, for I found I could do so without the glass breaking It may be that the holes in the tray of my steriliser are of the right size (they are about $^1/_4$ in. in diameter), but I believe this is a very usual size in sterilisers My original reason for abandoning lint was because I disliked unwrapping syringes with a hot wet compress round them—particularly when in a hurry At the present price of lint and gauze their omission saves money as well as time

Manchester 16. S SHUBSACHS

PERIODICALS FOR OVERSEAS

Mr Mark Gibbs, senior history master at the Grammar School Audenshaw Lancashire writes: "Very many students in overseas schools and colleges would welcome second hand copies of THE LANCET and similar journals, which they are unable to afford for themselves. The senior boys of this school (already operating a periodicals scheme for refugees) are therefore starting a posting scheme to be known as Periodicals for Overseas. We already have the addresses of some 40 colleges which have asked for supplies, and we can provide helpers with ready addressed labels and ample instructions for posting Further details will gladly be sent on request. Journals should *not* be sent to Audenshaw

Parliament

Genetic Effects of Nuclear Explosions

ON March 22 Dr EDITH SUMMERSKILL asked the House of Commons to consider the long term and remote effects of continuing nuclear explosions and the dangers of continuing radioactive contamination of the world's atmosphere particularly to future generations. Scientific investigations in this field must necessarily be limited, but we would she held be *irresponsible to ignore the* reports that had been made. To date there had been 65 nuclear explosions—50 by the Americans, 12 by the Russians and 3 by the British—and scientists were now expressing the opinion that these explosions could not continue without the danger of serious damage to health

The professor of biophysics in the medical school of Osaka University in Japan, had reported in people exposed to the Bikini test explosion of March, 1954, serious injury to the blood forming organs and the reproductive organs Undisputed evidence showed that a pregnant woman, exposed to only a moderate dose of radiation, ran the risk of aborting or giving birth to a stillborn child

The Federation of American Scientists, she continued, had suggested that the United Nations should appoint a commission to explore the dangers of continued nuclear explosions Mr Strauss the chairman of the Atomic Energy *Commission of the United States*, had reported that the fall-out from the hydrogen bomb could contaminate an area of 7000 square miles with lethally radioactive material. In this country Lord Adrian had said that the hydrogen bomb might "lead to a degree of radioactivity which no-one can tolerate or escape and thus end the human race"

[2] *Arch. Dis Childh.* 1954 29 165
[3] Annotation *Brit. med J* Jan 8 1955 p 93

[4] Brown R J K *Ibid* 1951, ii 1033

Mr IAIN MACLEOD, who stressed that he spoke on behalf of the Government, agreed that this problem offered a personal challenge to everyone which could not be shuffled off on to our leaders, on to our leader-writers, or on to the scientists Turning to steps already taken, he said that the Medical Research Council had had committees considering the subject for eight or ten years Represented on these committees, which were not Government bodies, were leading authorities from the universities, from the M R C research staff, and from the atomic energy authorities

There was nothing new in human beings being exposed to radioactivity We, and our ancestors, and all our evolutionary predecessors, he pointed out, had been exposed to radioactivity from outer space Each of us absorbed natural radiation of about 0 1 rontgen each year According to the U S Atomic Energy Commission the total amount of radiation received by residents in the United States from all nuclear detonations was about 0 1 röntgen Our calculations, derived from the Atomic Energy Authority, showed that the figure for somebody in this country would be about 0 03 rontgen This figure was based on the improbable assumption that a man stands outside in the open for 24 hours a day for about 50 years The effective average dose would in fact be considerably less Indeed, at the present levels of irradiation it seemed improbable that we had anything more than an interesting basic scientific problem and a situation which must be watched very carefully indeed

The real question, of course, was what was the threshold of radioactivity (which, if we are not there yet, we may reach in the future) beyond which man's genetic constitution might stand at risk The dose of radiation accepted as a maximum level for workers on radio-isotopes or for radiologists was 0 3 röntgen per week, or, taking working hours and holidays into account, about 15 röntgen a year That was enormously greater, of course, than any of the figures which the House had been discussing, but where large numbers of the community had to be considered the number of genes at risk was enormously increased, and therefore the number of matings which might be harmful was also increased He had tried to find a figure at which danger would begin, but the more he went into the subject the more he found that the scientists disagreed Estimates of the dose of radiation over a generation that was likely to double the spontaneous mutation-rate had varied from 3 röntgen to 300 rontgen He was told that 50 rontgen over 25 years was as good a guess as could be made The increase in the United States of America had only been a tiny fraction of this, and in this country it had been still smaller

The United States Atomic Casualty Commission had been studying the population in the vicinity of atomic explosions during the late war There was evidence that some conditions had a higher incidence among these populations, but no statistically significant evidence of genetic damage Studies of people such as radiologists and patients who for therapeutic reasons had to have considerable doses of radiation had not shown any evidence of genetic damage Dr BARNETT STROSS interposed that an American study of women treated with radiation for menorrhagia showed that among them the incidence of children born with congenital heart-disease and dislocation of the hip and clubfoot had increased

In this country, Mr MACLEOD continued, research was proceeding under the auspices of the M R C in the research unit at Harwell, and there were other research institutions at Hammersmith Hospital and Leeds The work was also being supported in many university departments For the M R C's work in their own establishments on all aspects of the effects of radiation £208,000 was allocated in the provisional estimates for 1955–56 If the council found that an increase was essential, this would have the favourable consideration hancellor of the Exchequer

The Problem of the Aged

In the House of Lords on March 28, Lord BEVERI suggested that many of the social and human problem of the aged were due to the fact that though the dec of our faculties was inevitable, the rate at which it car was uncertain The change in the age-structure of population also created difficulties In 1951 we ha 6,750,000 people of pensionable age, and about the sam number of working age, and fewer than 6 million children By 1979 there would be 9,500,000 people of pensionable age and there would still be about the same number of people of working age The Chancellor of the Exchequer would have to find something like £500 million a yea for pensions over and above what was paid by national insurance

But the problem, he maintained, was not mainly one of money The economic and social problems of the aged could not be solved by simply handing money to the pensioners Besides pensions old people needed care of many and different kinds—care of a perpetually changing amount and character, ranging from the car needed by those chronically sick in hospital, through occasional medical and nursing treatment, to perhaps no care at all The natural agent for giving care to old people was the family, but owing to the change in the population structure the family today was not physically able to do as much as formerly

The aim should be to keep the elderly in their own homes, but if this was to be done there should be adequate machinery for discovering the growing failure of strength which made transfer to a hospital, or other treatment necessary to avoid human tragedy The National Assistance Board did its work well, but it had only 1,250,000 old people on its books and there were 7 million elderly people In each neighbourhood there should be someone to whom neighbours could report an old person in need of more care At present something like 1 million elderly people were living by themselves, and old peopl trying to live in their own homes should have adequat help The present provision of home helps—30,000, o whom 3000 were full-time and 26,000 part-time worke —was ludicrously small

There must also be some half-way houses between t hospital providing full treatment and the home Loc authorities were empowered under the National Heal Service Act to establish these homes, and the powe had been largely used A number of local authoriti had also lately asked the Ministry of Health for pe mission to provide a chiropody service as part of t N H S, but the Government had replied that they h other, and greater, priorities for the health service Lord Beveridge's view the £14 million subsidy to cheape tobacco for all pensioners, many of whom were wome could be more usefully spent on providing home hel and chiropody

Lord AMULREE, returning to the problem of findin out in time when an old person is in need of care an help, said that the London borough where he worke had a population of 140,000 During the last six month roughly 200 old-age pensioners of sixty-to sixty fiv had applied for admission to hospital 90 of them live alone, and of these 40 were living in a state of dirt an squalor Most of them were so neglected that the needed a lot of good food and tidying and cleaning u The tragic thing was that in six months in one Londo borough 40 people were living in such conditions Wh an enormous reservoir of human misery must exist the rest of the country

The EARL OF SELKIRK, replying to the debate, said th old people should be enabled to remain at work as l as possible, to remain in their own homes, and never to fe that they had ceased to be part of the communit The home-nursing service was still expanding, th number of nurses employed had risen from 7700 in 19 to 9500 in 1953, and the number of cases attended h increased by about 40% He agreed that the number home helps was only 30,000, but in 1948 it had b only 11,000 There were also sitters-in and n watchers provided by some local authorities a voluntary organisations The money spent on tobac was an example of the unsatisfactory result of making benefits available by coupon, but in practice it was difficult to withdraw concessions, Chiropody was available in hospitals and in some clinics, and home treatment could be provided under the National Assistance Act, but he agreed that the service was inadequate An automatic method of discovering people who were in hardship was difficult to visualise Surely this was a matter in which anyone, whether it be a neighbour a general practitioner, or even a rent collector, could act by *reporting the circumstances either to the local council or to* the National Assistance Board He thought that more was being done in the way of coördination of services than was generally appreciated He believed that it was hoped shortly to institute meetings between medical officers of health *and general practitioners* *Local authorities* in ngland and Wales had provided 60 000 beds, of which at ast 50 000 were available for aged persons. Since the id of the war some 800 new small homes with accom odation for 23,000 people had been opened by local thorities. There were registered over 1200 small omes with another 23,000 beds He felt that whatever ction we took it was essential that old people should main useful, *independent*, and wanted this objective epended as much on each citizen as on the State

QUESTION TIME

Tuberculous Patients in Swiss Sanatoria

Replying to a question Mr MACLEOD said that the Ministry f Health began to send patients *to Davos in the autumn of* 951 when waiting lists for tuberculosis beds in England nd Wales stood at over 7000 The provisional figure for he end of 1954 was 2500 and this of course included a large umber of patients who were on the point of being admitted t once. Several hospital regions now had virtually no waiting st. Some were closing tuberculosis beds or turning them over o other purposes. Well over 900 patients from England and Vales had been sent to Switzerland by the National Health ervice, and this had been a most valuable contribution to he work against respiratory tuberculosis. But taking into ccount the diminished pressure today on tuberculosis beds t home and the recent difficulty in finding enough suitable atients willing to go to Switzerland for treatment he was atisfied that there was no necessity to extend the scheme eyond this autumn, when the contracts with the sanatoria xpired Suitable arrangements would be made for winding t up so as not to discharge patients from the sanatoria in Davos before they were fit

Commander T D GALBRAITH in a statement on the Scottish scheme said that over 900 patients from Scotland had gone to Switzerland During the past twelve months the total waiting list had fallen from just under 2000 to around 500 Chest physicians *were finding it increasingly difficult to* fill the beds in Switzerland. Patients were now coming forward from four areas only—Glasgow Renfrewshire Dunbartonshire and Stirlingshire They could not usefully send any more patients to the Sanatorium Wolfgang where they had had the use of 70 beds. For the present they were continuing to send patients to the Sanatorium du Mont Blanc where they had the use of 120 beds, which would be sufficient to accommodate all the *patients* coming forward under the scheme If present trends continued the *time might not be far distant* when it would be possible without prejudice to the treatment of Scottish patients to reduce still further the scale of these arrangements and eventually to terminate them altogether

Counteraction of Nuclear Explosion Effects

Replying to a question Mr HAROLD MACMILLAN, Minister of Defence said that experiments had been started under the *authority of the Minister of Supply to test the uses of smoke* in counteracting the effects of nuclear and thermonuclear explosions. The results would be of interest both to Civil Defence and to the Services.

Conservative Dental Work in Scotland

Replying to a question Commander GALBRAITH said that the number of courses of dental treatment other than emergency extractions and the supply of dentures, *in Scotland* increased from 603 000 in 1951 to 715 000 in 1954 Most of these courses were for conservative work

Obituary

HENRY MARRIAN JOSEPH PERRY

C.B., O.B E., F R.C.P L.R.C.P I

Major-General Marrian Perry director of pathology at the War Office in the early part of the late war, died on March 23, at his home at Walton-on Thames, at the age of 71

Son of the late John Perry he was educated *at Queen s* College Cork, and joined the Royal Army Medical Corps soon after qualifying in 1906 In the 1914–18 war he was a regimental medical officer, commanded a field ambulance, and became assistant adviser in pathology in France In 1918 his experience of agglutination tests *for* enteric infection in men inoculated with T.A.B vaccine was described in a long paper in our columns, with a note by Sir William *Leishman* Meanwhile he had investigated with Captain (now Sir Henry) Tidy an epidemic of aertrycke infection at a depot, and their account of this was one of the early special reports of the Medical Research Committee His bacteriological work continued with *contributions on bacillary dysentery, on the* anti genic properties of ' Bacillus psittacosis, ' on leishmaniasis, and on the flocculation test in syphilis. Some of it was done as assistant professor, and later professor, of pathology at the Royal Army Medical College but in 1926 *he was seconded from* Millbank to work for four years as director of the public health laboratories in Cairo To this period belongs the essay on the practical diagnosis of typhoid and paratyphoid infections which he and H J Bensted wrote for the Medical Research Council s *System of Bacteriology* (1929)

Returning to pathology at Millbank, Perry was appointed honorary surgeon to the King in 1933, and reached the rank of *major* general in 1935 As Director of Pathology at the War Office he was chairman of the Army Pathology Advisory Committee *and also a member* of the Chemical Defence Committee From these posts he retired in 1941

Marrian Perry will always be remembered as a brilliant teacher by all officers who attended his lectures at the Royal Army Medical College, writes L T P

One of his many gifts was his extraordinary command of English which always fascinated his students and at times delighted them by the artistic way he would round off his sentences His enthusiasm for his subject, and the energy he displayed, never failed to inspire He was quick, dapper and courteous, and as he entered the lecture theatre—always immaculately dressed—his commanding presence immediately *arrested attention.* He would take great care to make his subject interesting and to relate it to other branches of medicine An hour s lecture would slip away into what seemed like moments He had the gift of displaying facts in a simple way—always the mark of a good teacher

In his capacity as *Director of Pathology* he was exemplary in the high standard he set He lived for his subject and for the health of the *Army and would* go to endless trouble to further research. The team spirit in his department was indeed high, for he inspired confidence and was sympathetic and approachable Those who specialised in *pathology under* his guidance have cause to be grateful for the help and encouragement he gave them Among his colleagues in all branches of *medicine* he was held in high esteem and his opinion was sought on many problems. His judgment was sound; this had the effect not only of enhancing his own *reputation but also that* of his department In the mess he was the best of company and with his quick repartee a most entertaining after-dinner *speaker* *His many accomplishments* and his wisdom made him a unique personality in the Corps. The name of Perry will always be linked with the highest *traditions* of pathology in the Army "

General Perry was appointed O.B.E. in 1919 and C.B. in 1937, *and in 1941 he was elected* F.R.C.P He married in 1912 a daughter of the late E G Brower

AGNES CATHARINE SCOTT

C.B E., M.B Lond

Dr Agnes Scott, who died *in* London on March 22 had given many years of life and valuable service to India as chief medical officer of the Women s Medical Service

She was born in 1875, the second daughter of Canon John Scott of Leeds, and went to school at the Leeds Girls' High School and Yorkshire College She studied medicine at the London School of Medicine for Women and qualified in 1901 She had entered the medical profession with the definite idea of serving as a missionary in India, and she went out to that country in 1903 to serve with the Cambridge Mission to Delhi Her first years were spent in Karnal, a small station in the South Punjab, and afterwards she was moved to Delhi Both experiences were valuable to her in her later work since one was a rural area and the other an urban one The hospital in Delhi was at first in the middle of the old city, but during Dr Scott's time it was moved to the " Civil Lines " where there was more air and space. The experience of helping to build a new hospital was also valuable for her subsequent work

In 1917 a partial breakdown in health led her to accept the post of assistant to the inspector-general of civil hospitals in the Punjab This post had been created only a few years before and was first held by Dr M I Balfour, whom in 1924 Dr Scott again succeeded as chief medical officer of the Women's Medical Service In 1925 she was awarded the Kaiser-i-Hind gold medal and in 1932 when she retired she was appointed C B E

R Y writes " Dr Scott's gifts were essentially practical In the Punjab she was interested in the building and equipment of small hospitals in rural areas as well as encouraging existing mission and government hospitals in larger centres She also did much to improve the practice of midwifery in rural areas by encouraging the training of the Indian midwives and the creation of assistant nurse midwives who were capable of simple nursing and midwifery

" She showed the same gifts when she became head of the Women's Medical Service It was a time of change and development in India, and medical women shared in both Dr Scott realised that the service would ultimately be an Indian one and she was anxious that those who entered it should be well qualified for their responsibilities She also grasped the need for specialisation among some members of the service, particularly those who might become members of the teaching staff of the Lady Hardinge Medical College For this purpose she created the ' training reserve ' of the service by which promising graduates of Indian medical colleges could be sent abroad on scholarships She was interested in all forms of health work and she fostered their development Her devotion to high standards in professional work and her personal integrity were an outstanding example to members of the service

" Dr Scott was a keen churchwoman, and after her retirement she gave much time to the work of medical missions Her wide experience made this a valuable piece of service By nature she was reserved and not easy to know, but her occasional hot temper was a human touch which was accompanied by a sense of humour and a love of dogs Behind her reserve was a warm heart which showed itself in many kind thoughts and actions and in real devotion to her friends and to the Church "

FREDERICK HECTOR SCOTSON

M.B Manc and Lond , F R C.S

Mr Scotson, consulting surgeon to the Crumpsall Hospital, and Northern Hospital, Manchester, died on March 23 at the age of 55

He was born in Manchester, where his father was a well-known general practitioner, and he was educated at the Grammar School and the university where he won prizes and distinctions He continued his medical training at St Bartholomew's Hospital, and in 1922 took his London and Manchester degrees, the latter with honours He took his F R.C.S at the age of 24, but he had to wait a year for his diploma on account of his youth He held the usual resident posts at the Manchester Royal Infirmary, where he was a notably successful resident surgical officer

He visited the Mayo and other American surgical clinics before he started consultant practice in 1929 He on appointed to the staffs of the Crumpsall, t' ster Northern, and the Manchester Victoria Memorial Jewish Hospitals, and he helped to establish St Joseph's Hospital, a big Catholic charitable nursing home He was also a lecturer in surgery at the university As a general surgeon he had a busy life, but he found time for specialised interests His early writings on genito-urinary surgery included papers on malignant tumours of the kidney and testicle More recently he had turned to the surgery of the gastro-intestinal tract, and he was due to give an account of his experience in the treatment of peptic ulcer as his presidential address to the section of surgery of the Manchester Medical Society

W B , writing of Scotson's early days, recalls how " during his term as R S O he succeeded in breaking the rule against marriage, a cleverly handled and notable triumph. Later in the few respites he could snatch from his work he loved a holiday where he could ski or bathe in sunshine He was a good swimmer, having won his colours at the university, and continued to take active interest in the university swimming club He was a keen golfer and tennis player There can be little doubt that the energy he put into his surgical work brought on the illness which had troubled him in the last nine months "

Mr Scotson leaves a widow and four children, the eldest of whom is a medical student

RONALD GREAVES LADKIN

M.B E , M.A , B.M Oxfd, D.P.H

Dr R G Ladkin, senior medical officer in charge of health education in the Uganda medical department, died at Kampala on March 14, at the age of 35, from poliomyelitis

Educated at Kingsbridge Grammar School and Exeter College, where he was Stapledon scholar and Devon scholar, he graduated in medicine at Oxford in 1942, and was house-physician at the Radcliffe Infirmary He joined the Uganda medical department as a medical officer in 1943, and after serving in several districts became lecturer in anatomy at the medical school of Makerere College, Kampala At Mulago Hospital he undertook genito-urinary surgery and thus became interested in venereal diseases Of these he made a special study, and after taking his D P H. in 1948 he visited Trinidad to see methods of prevention and treatment in that area On his return to Uganda he became medical officer of the rapidly advancing Mengo district and was soon promoted to be in charge of the province of Buganda

It was in these country districts that he showed exceptional talent and industry, throwing himself with great energy and understanding into many measures of public health He developed quite new approaches to the problem of rural health in tropical Africa health weeks and large demonstrations along novel lines were held at many centres His achievements in this field won him appointment as M.B.E , and a new post was created for him at medical headquarters, Entebbe Both within and outside the territory he was in much demand, for he had a knack of combining the latest methods of visual education with a close knowledge of the African countryside and the psychology of the peasant farmers He had built up a unique collection of films, posters, and booklets, and he received grants from international organisations to promote the work of health education

A colleague writes of his " endearing personality which attracted his associates and won a place of real affection among the many Africans whom he served so generously He saw more clearly than most the factors responsible for disease and malnutrition in Africa He was essentially creative in all his work, full of good spirits, counting nothing of the financial stringency and other exacting conditions under which he worked He seemed to take a special delight in long spells as a fast bowler under the tropical sun and in himself carrying parts of the huts that were assembled to accommodate climbers on the upper slopes of Mount Ruwenzori He revelled in difficulties, not only those considered spectacular but those which were more prosaic For instance, the su of the Red Cross blood-transfusion service in owes a great deal to his skilful propaganda in spite much superstition among those Africans whom he endeavouring to help He felt that health edu which consists in changing the minds of people, would always be a difficult affair '

Dr Ladkin married Miss Heloise Carter, a nursing sister of the Uganda medical department, and there are three children

Medicine and the Law

Air Embolism during Artificial Pneumoperitoneum

At an inquest on a woman of 23 who died during the course of an artificial pneumoperitoneum injection for pulmonary tuberculosis, the cause of death was stated to be air embolism from accidental injection of the air into a vein. The operation had been carried out in a chest clinic by a doctor with wide experience of the procedure. A consultant chest physician said that in his opinion the doctor had used the recognised method in performing the operation. A verdict of death by misadventure was recorded.[1]

Diary of the Week

APRIL 3 TO 9

Tuesday, 5th

ROYAL COLLEGE OF SURGEONS OF ENGLAND Lincoln's Inn Fields W C 2
5 P.M. Mr V E. Negus Comparative Anatomy and Physiology of the Respiratory Tracts in relation to Clinical Problems. (Lister oration.)

Wednesday, 6th

ROYAL SOCIETY OF MEDICINE, 1 Wimpole Street, W 1
5 15 P.M *History of Medicine* Prof. G R. Cameron F.R.S.: Von Kolliker Dr Brice Clarke Katherine Mansfield's Illness
MANCHESTER MEDICAL SOCIETY
4.30 P.M. (Medical School.) *Medicine* Prof. Robert Platt: Life (biological not biographical)

Thursday, 7th

ALFRED ADLER MEDICAL SOCIETY
8 P.M. (11 Chandos Street, W 1) Prof Alexander Kennedy: *Human Reactions to Danger*

Appointments

BOYD T A S, M.B. Glasg F.R.C.S. D.O.M.S part time ophthalmic surgeon, Bangour Hospital, Broxburn West Lothian
CLARKE D M. P R. M.B. N U.I. D.M.R.D radiologist, Mayo county council.
DE WITT W H DE W M.CH.ORTH Lpool F.R.C.S., F R.C.S.I.: orthopædic surgeon, Meath county council
FAIRLEY H BARRIE, M B. Lond., F F.A. R.C.S., D.A.: anæsthetist, Toronto General Hospital and clinical assistant, University of Toronto
HENRY H S A. M.B. Belf. F.R C.S. D.P.H., D.L.O: part time consultant E.N T surgeon South Down and South Armagh group of hospitals.
O'SULLIVAN R. F M.B N U I D.P.H: appointed factory doctor Shelf York.

Birmingham Regional Hospital Board:

ANTON-STEPHENS DEREK M.B Dubl., D P.M. whole-time psychiatrist and deputy medical superintendent Highcroft Hall Hospital
HAWKINS C F., M.D Lond. M R.C.P part time consultant physician, mid Worcestershire group
STROUD M H., M.B. Birm. F.R.C.S: part time consultant E.N.T. surgeon, Birmingham (Dudley Road and West Bromwich groups)
THOMSON J F., M.D Edin. D P.M whole-time consultant child psychiatrist Shrewsbury and Wolverhampton groups
TUDOR, R. W., M.B. Birm, F.R.C.S. whole time senior casualty officer Birmingham (Selly Oak group).
WALSH PETER, L.R.C.P.I. part time asst. [illegible] Wolverhampton group

Manchester Regional Hospital Board:

CHADWICK, D A., M.B. Manc., F.F.A.R.C.S. consultant group anæsthetist, north and mid Cheshire hospital group
CHANDRA, PRAKASH M.B. Lucknow M.CH.ORTH. Lpool, F.R.C.S. senior casualty officer Burnley and district hospitals
CHATTERJEE, S S M.B. Patna, M.R.C.P whole-time asst. chest physician, Baguley Hospital, Manchester
JEWSBURY PERCY M.B. Manc., F.R.C.S. [illegible] surgeon Blackpool and Fylde Hospital [illegible] northern part of the region.
SMITH, A E. M.B. Edin., F.F.A.R.C.S. consultant anæsthetist Bolton and district group of hospitals
TUTTON G K., CH.M. Manc., F.R.C.S. consultant neurosurgeon, Preston and Chorley Hospital Centre and northern part of the region.

Notes and News

MENTAL-HEALTH RESEARCH

The first research fellow to be appointed by the Mental Health Research Fund Dr J D Montagu was presented to those who had gathered at the Mansion House on March 23 to hear more about the fund's future plans. Sir SEYMOUR HOWARD the Lord Mayor spoke of the advances in treatment and prevention of mental ill health which the work of the fund may reasonably hope to forward. Dr W S MACLAY introducing the speakers, mentioned three main lines by which research in this field is at present advancing: by sociological studies of the incidence of mental illness and the like, by studies of the individual by psycho-analysis and allied methods and by studies of an organic nature into the physiology biochemistry and electrophysiology of the brain. For the present, he said the fund is confining its scope to the third of these. Dr DENIS HILL spoke of the light electro-encephalography has already thrown on epilepsy and of its value in locating cerebral tumours. He described cases of epilepsy originating in the temporal lobe which have been treated successfully by removal of the brain area in which the epileptic discharge takes place. In the last four years, he said 50 patients have been treated in this way and results have so far been encouraging over half have been freed from fits and 85% have been greatly helped.

Dr ELIOT SLATER speaking of the genetic aspects of mental disorder recalled that one of the first diseases in which an inherited factor was recognised was a mental disease—Huntington's chorea. Other mental disorders do not give such clear evidence as this but studies of siblings, and especially of uniovular twins, have already shown that genetic factors operate in mental illness. This, he said does not mean we need despair about mental disorders: the inherited factors are of a biochemical nature and presumably will in time be as open to treatment as other disorders of body chemistry. Moreover the mental health of the person depends not only on his heredity but also on his environment and the stresses to which life exposes him. He cited a pair of uniovular twins, one of whom became a criminal while the other led an equally exciting and dangerous life without finding it necessary to turn to crime. Prof. J ELKES spoke of the use of drugs in research and treatment, and the information being gained from studies of hallucinogenic drugs, and also from the effects of 'Sodium amytal' in rousing schizophrenics temporarily from stupor. Through such studies as these, he said we may come in time to detect early mental illness by chemical means, and perhaps to suggest antidotes.

In concluding the meeting Sir GEOFFREY VICKERS said that some might ask what need there was for this fund when the Medical Research Council and the Clinical Research Board already administer funds for research. He thought it wrong, he said, that research in any field should rely for support on a single public source, however well administered. In a voluntary enterprise, such as this fund, interest is canalised and specific made of the commonly encountered problem of the employee who believes, against medical evidence, that his work is undermining his health

---

[1] *Liverpool Daily Post*, March [illegible]

The floor above deals with some of the commoner industrial and occupational hazards Posters and drawings bring home the need for simple common sense precautions—e g , the importance of wearing protective goggles in any process involving a risk to the eyes, and the wisdom of making sure that electrical fittings are soundly constructed and regularly inspected Finally, there are some interesting exhibits relating to the factory canteen these demonstrate the folly of guarding the worker against trauma while leaving him exposed, during his lunch hour break, to the more subtle menace of *Salmonella typhimurium*

THE OTHER SIDE OF THE TABLE

APPLICANTS for posts in medicine, as in other professions, are expected to pass an examination for which their training has not specifically prepared them Some bring a native shrewdness to the task, and do well , others, equally well fitted for the post, are defeated by native shyness Not a few, perhaps could learn something to their advantage from *The Intelligent Teacher s Guide to Preferment*,[1] in which a director of education offers advice from the selection committee's side of the table Having dealt with such important details as the candidate's application form and covering letter and his choice of referees the author reminds candidates that though they may be ill at ease at the interview, so also may be the inter viewing committee "The wise candidate makes a swift assessment of the situation and does his best to put the committee at their ease, however many butterflies may be fluttering in his own stomach"

Royal College of Obstetricians and Gynæcologists

Mr Vincent Massey, Governor General of Canada, and Dr George W Corner, of Baltimore, will be admitted to the honorary fellowship of the college on July 22

Prof B P Watson, of Columbia University, New York, has been elected William Meredith Fletcher Shaw lecturer for 1955

South West Metropolitan Region

Chest Diseases Group (Eastern Area)—The inaugural meeting of this group will be held at St James' Hospital, Balham, at 2 30 P M on Saturday, April 23, when Sir Clement Price Thomas will speak on Carcinoma of the Lung

U.S Surgeon-General

Major General Silas B Hays, Army Medical Corps, has been appointed surgeon general of the United States Army, in succession to Major General George E Armstrong, who is retiring

Faculty of Anæsthetists

The seventh anniversary dinner of the faculty was held in the Royal College of Surgeons on March 23 Proposing the toast of The Faculty, Sir Charles Dodds said that the last twenty years had witnessed a revolution in the practice of anæsthesia No longer had patients to undergo the rigours of rag and bottle induction or endure the gastro intestinal qualms that followed return to consciousness Thanks to basal anæsthetics, these were things of the past , it was unfortunate, he reflected that some equally effective technique was not available to after dinner speakers to facilitate the descent of their audiences into welcome unconsciousness In reply, Dr Bernard Johnson, the dean spoke of the faculty's responsibilities in the fields of teaching, clinical practice, and research The new anæsthetic research department to be established within the college had been most generously supported by pharmaceutical firms As a result, the faculty would continue to lead the world in the advance of anæsthesia Dr R F Woolmer, vice dean, welcomed the guests in rhyming iambic pentameters—an orthometrical tour de force that provoked enthusiastic applause Replying, Sir Russell Brain disclaimed poetic skill but went on to leave no doubt as to his mastery of prose He noted that anæsthesia, having been the companion of surgery for a century, was now being wooed by medicine Already it had established a place for itself in psychotherapy and there was growing evidence of its value in the treatment of tetanus and bulbar poliomyelitis—facts which proved once again that the more specialised specialties become, the more dependent they are on each other

Queen's Institute of District Nursing

Dr G O Barber is to speak at the conference which this institute is holding at Church House, Westminster, S W 1, on Thursday, May 12, at 2 30 P M , on the Link between Hospital, General Practitioner, and the District Nursing Service

Harveian Society of London

Buckston Browne Prize—The subject chosen for the essays for this prize (£100) for 1956 is Hypertension Entry is open to any doctor, registered in the British Isles or Dominions, who is under 45 years of age Essays must be sent by Aug 31, 1956, to the hon. secretaries of the society, 11, Chandos Street, W 1

Association of Sea and Air Port Health Authorities of the British Isles

The annual general meeting of this association is to take place in London from June 8 to 10 Dr R H Barrott will give a general review of the state of port health administration at the present time, and Dr W D L Smith will speak on Malaria and the Thames

Basingstoke Plastic Centre Medical Society

On Thursday, April 14, at 7 30 P M , at Rooksdown House (Park Prewett Hospital), Basingstoke, Hants, this society will hold a meeting on burns with special reference to the effects of atomic explosions The speakers will include Prof R H. S Thompson, Dr W J Butterfield, Dr P Gorer, Mr Douglas Jackson, and Dr J P Bull

European Rheumatology Congress

This congress is to be held at The Hague from June 13 to 17 The programme is divided into sections on rheumatic fever, connective tissue, osteo arthritis of the spine and disc degeneration, and rheumatism and social medicine Speakers from this country will include Dr E G L Bywaters, Dr L E Glynn, Dr R Consden, and Dr E J Holborow Further particulars may be had from the secretary, Dr H van Swaay, Burg De Monchyplein 9, The Hague, Holland

Welsh National School of Medicine

Dr A Trevor Jones, senior administrative medical officer of the Welsh Regional Hospital Board, is to succeed Prof R M F Picken as provost of the school Professor Picken retires on Sept 30

Dr Jones was educated at the Lewis School, Pengam and he began his medical studies at the University College of South Wales and Monmouthshire in Cardiff before going to University College Hospital London where he qualified in 1924 After spending some years in hospitals in London he returned to Wales in 1929, taking hospital appointments in Swansea and Carmarthen, where he also worked in general practice and became the medical officer of health He was appointed a medical officer on the staff of the Welsh Board of Health in 1935, and during the late war he was the hospital officer for Wales under the Emergency Medical Service Since the start of the National Health Service he has been the senior administrative medical officer to the Welsh Regional Hospital Board He was elected F R C P in 1953 His publications include the report of the survey of the hospital service in South Wales which he carried out in association with Professor Picken and the late Professor Nixon, of Bristol, in 1945

British Society for Research on Ageing

The following honorary officers and members of the executive committee have been elected

Chairman, Sir Charles Dodds, F R S , vice-chairman, Sir Francis Fraser, secretary Mr G H Bourne D SC (London Hospital Medical College London E 1) treasurer Prof P L Krohn, members of committee, Prof J F Danielli D SC , Miss H B Fell, F R.S Prof K J Franklin F R S , Prof P B Medawar, F R.S., Prof R E Tunbridge

Current Conceptions of Allergy

The Society for Visiting Scientists is to hold a meeting on this subject at 5, Old Burlington Street, London, W 1, on Wednesday, April 6, at 7 30 P M Sir Henry Dale, O M , F.R S., will be in the chair and the speakers will be Dr Bernard Halpern, director of research at the Centre National de la Recherche Scientifique, Paris, Prof J R Marrack, and Dr J Pepys

Second International Congress of Neuropathology

This congress will be held in London from Sept 12 to 17 The programme includes discussions on the Pathological Basis of Involuntary Movements, the Neurone, the Blood brain Barrier, Malignancy and Classification of Gliomas, and (with the Symposium Neuroradiologicum) Tentorial Herniation of the Uncus Further information may be had from Dr W H McMenemey, Maida Vale Hospital for Nervous Diseases, W 9

The Queen has consented to the title "Royal" being given to the Australian Flying Doctor Service

THE URÆMIAS*

G M BULL

M.D Cape Town F R C.P

ROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY, BELFAST

THE word uræmia means urine in the blood and was rst used by Piorry and Lhéritier in 1840 to indicate the toxication resulting from insufficient purification of the lood by the kidneys It is unfortunate that it is such a hort and descriptive word, for it sounds as if it indicates ne definite clinical picture. In fact it does not

In renal failure one may see a very wide variety of ymptoms and signs which even on Piorry's definition, ould be included as uræmic. With improving bio hemical knowledge it has become possible to attribute ome of these to measurable deviations from the normal ody chemistry I shall aim to review some of the rogress in this field and to show how a better under tanding of the pathogenesis of the uræmias may lead to ional treatment

Definition

The uræmias are those states which occur when the kidneys unable to maintain a normal internal environment, d arise when there is an imbalance between the rates of take or production in the body of chemical substances and ir rates of excretion

This definition emphasises three important points

(1) There is no single clinical picture in renal failure

(2) The uræmias arise from an imbalance between intake d renal function—a concept of great importance in treat ent

(3) Uræmia includes those states which arise from failure the kidney to conserve essential substances as well as states e to retention of urinary constituents.

PATHOGENESIS OF SYMPTOMS AND SIGNS IN THE URÆMIAS

Contrary to earlier beliefs the most important sub tances in the genesis of the uræmias are not the organic nd products of nitrogen metabolism but water and lectrolytes.

Some of the uræmias can be attributed to detectable eviations from the normal chemical content of the body, nd can be recognised by clinical and laboratory methods hese will be described first Others remain unexplained nd will be considered more briefly later

Although each uræmia is described as though it were separate entity it should be remembered that mixed varieties are the rule In each case are outlined the mechanisms of production then the clinical recognition, nd finally the laboratory diagnosis

Symptoms and Signs Attributable to Known Biochemical Abnormalities

ACIDÆMIA

Acidæmia develops when the ratio of strong anion to ixed base rises This may occur in renal disease for the ollowing reasons :

1 The intake of anion (particularly chloride phosphate and ulphate) may exceed the capacity of the kidney to excrete it

2. Fixed base may be lost owing to a defect in renal base-paring mechanisms

3 Fixed base may be lost in diarrhœic stools.

The clinical picture is dominated by the deep sighing espiration and thus is accompanied by various degrees of clouding of consciousness progressing to coma [1] Other symptoms frequently occur in acidæmic patients, but whether they are the result of the acidæmia, or due to associated disturbances, is difficult to say The most common accompaniments are restlessness, headache, and nausea and occasionally there is meningism.

The diagnosis is confirmed by determination of the plasma bicarbonate ($-HCO_3$) level which is reduced in metabolic acidæmia This level is similarly reduced in respiratory alkalæmia from hyperventilation, but in this latter the pH is raised, and tetany (overt or latent) can be demonstrated Tetany does not occur in acidæmia, for reasons which are discussed on p 732

Although incorrect in a strict chemical sense, it is convenient to regard the reduction of the plasma bicarbonate level as a deficiency of fixed base in the body even where the cause is the presence of fixed anion in excess. This is so because, in treatment, we have to provide a quantity of strong cation to correct the disturbance Although we sample only the plasma this deficiency of fixed base is found throughout body water—information which is useful in calculating the quantities of base to be given in treatment

ALKALÆMIA

Alkalæmia is rather uncommon in renal failure and here as in other circumstances it is almost always associated with potassium deficiency That potassium deficiency is an important cause has been shown by Orloff et al (1953) The alkalæmia arises in most cases because of vomiting, with its attendant loss to the body of chloride and potassium but it is occasionally seen when there is a very high intake of alkali.

The clinical picture is usually dominated by tetany caused indirectly by a fall in the level of ionised calcium (The reasons for this are discussed on p 732) Some symptoms however, probably arise from the alkalæmia per se these include stupor, headaches and changes in temperament—or even psychosis Some patients notice a dislike of sweet foods

Estimation of the plasma-HCO_3 level confirms the diagnosis. A rise in $-HCO_3$ is found in metabolic alkalosis, *but also* in *respiratory acidosis* To distinguish between these two we may estimate the blood pH but in practice this is unnecessary because in metabolic alkalosis there is *tetany (latent or overt)* and in respiratory acidosis there is central cyanosis

HYPERPOTASSÆMIA

Little is known of the rôle of changes in cellular potassium content in renal failure and the main clinical importance of the potassium ion is that changes in its concentration in extracellular fluid sometimes give rise to symptoms and signs, and may cause death Hyper potassæmia occurs in the following circumstances :

(1) Potassium intake may exceed the capacity of the kidney to excrete it The reprehensible practice of administering potassium citrate as a diuretic in acute nephritis, and its routine administration to all patients receiving sulphonamides must have caused many fatalities in this way

(2) Potassium may be released from its protein binding in cells during katabolism and then migrate into the extracellular space This occurs particularly when the rate of katabolism is high as in anuric patients receiving too few calories in the diet and in those with infections It also occurs in underhydrated patients. Here the reason is probably as shown in fig 1 This variety of hyperpotassæmia may be seen even in the presence of a deficiency of potassium in the body as a whole and it is almost always seen in extracellular underhydration.

It is unfortunate that in most patients there are no presenting symptoms and signs of hyperpotassæmia. The patient dies suddenly of cardiac arrest Very rarely indeed, hyperpotassæmia may be accompanied by a flaccid hyporeflexic generalised paralysis, clinically indistinguishable from that which may occur with hypopotassæmia We certainly cannot afford to await the development of paralysis, and the diagnosis of hyperpotassæmia must be suspected from the attendant circumstances, and confirmed by estimating the serum-potassium level Where this is not possible, an electrocardiogram may be of assistance, because a very rough correlation exists between the serum-potassium level and the electrocardiographic pattern

* The Goulstonian lectures for 1955 delivered before the Royal College of Physicians of London on Jan. 18 and 20 Based on work done with Dr A M Joekes Dr K G Lowe and Miss B M Evans at the Postgraduate Medical School of London and with Dr R N Beck Dr R A Womersley and Miss E Martin at Queen's University and Royal Victoria Hospital Belfast

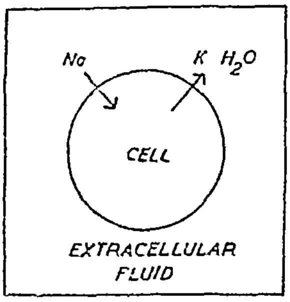

Fig 1—Effect of lowering partial pressure of oxygen on cell water, sodium, and potassium

The oligæmia resulting from underhydration causes a reduction in the general circulation, which in turn causes a fall in partial pressure of oxygen in the tissues and a reduction in renal function—circulatory renal insufficiency When the partial pressure of oxygen falls, potassium is released from the cells and passes into the extracellular fluid (Mudge 1951, Robinson 1953), where its concentration increases, because its excretion is impaired by the circulatory renal insufficiency

POTASSIUM DEFICIENCY

A deficiency of potassium arises when there is a combination of a low intake of the ion with excessive loss either through the kidney or through the gut It is seen characteristically in the following circumstances

(1) In the early diuretic phase of tubular necrosis, where it is presumably due to a defect in tubular reabsorption of potassium (Bull et al 1950)

(2) The same type of defect may be seen rarely in chronic renal disease (Bickel et al 1953, Brown et al 1944, Evans and Milne 1954)

(3) Potassium deficiency also arises because of loss of the ion, in excess of intake, in vomitus or in diarrhœic stools, both of which contain considerable quantities of potassium

Clinically, the hallmark of hypopotassæmia is a flaccid areflexic paralysis, indistinguishable, on neurological examination, from family periodic paralysis However, gross deficiencies of potassium may occur without this paralysis Usually in potassium-deficient patients there is some clouding of consciousness, but whether this is due to potassium lack or to associated disturbances is uncertain

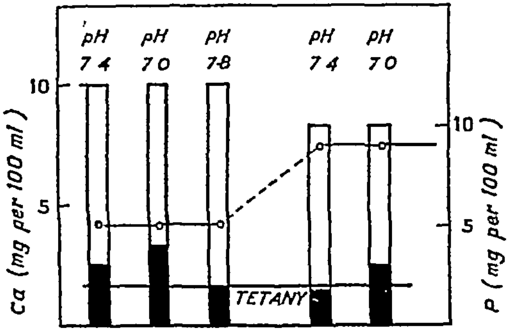

Fig 2—Effect of pH and serum-phosphate level on plasma-ionised calcium level

The proportion of total serum calcium level due to ionised calcium is shown in black In acidæmic patients (as in columns 2 and 5) the proportion ionised increases, and in alkalæmic patients (as in column 3) it decreases.

A rise in serum phosphate level above the normal (as in columns 4 and 5) is associated with a reciprocal fall in serum calcium level At a normal pH this may cause tetany, but 5 shows how acidæmia prevents the development of raising the proportion of calcium ionised.

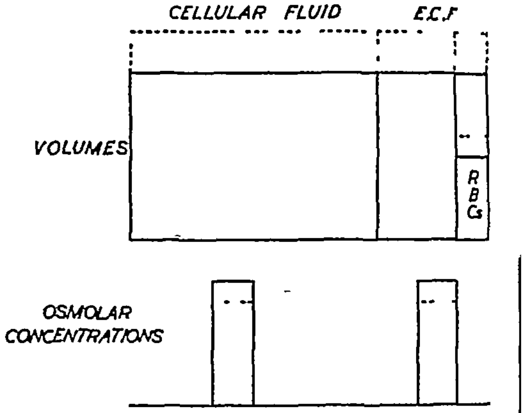

Fig 3—Cellular and extracellular overhydration

For comment, see text In this and subsequent simil figures the solid line represents the normal, and the dott line the abnormal

The diagnosis may be confirmed by determining th serum potassium level or by electrocardiography Unfortunately I do not know of any simple method of estimating quantitatively the extent of the deficiency of potassiu in the body as a whole

DISTURBANCES IN CALCIUM LEVEL

The level of ionisable calcium in the extracellul fluid may be altered in renal failure The most importa causes of these alterations are changes in the plasma p and the plasma inorganic phosphate concentration Their effect is shown in fig 2

The serum-inorganic phosphate level rises in parall with azotæmia when the glomerular filtration-rate reduced Secondary to this, there is a fall in level of serum calcium

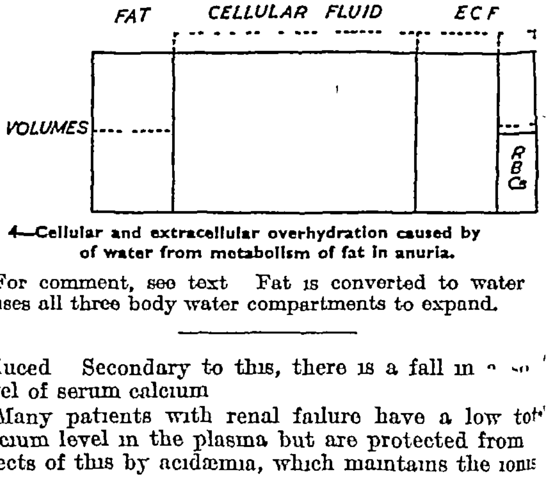

Fig 4—Cellular and extracellular overhydration caused by of water from metabolism of fat in anuria.

For comment, see text Fat is converted to water causes all three body water compartments to expand.

Many patients with renal failure have a low tot calcium level in the plasma but are protected from effects of this by acidæmia, which maintains the ionis fraction at near normal levels If the acidæmia corrected without a fall in the inorganic phosphate of plasma, they develop tetany Lowering of the level ionised calcium is one of the causes, though not a co one, of twitching and generalised epileptiform conv in renal failure

Hypercalcæmia is very uncommon in renal failure, where it occurs it is usually the cause rather than result of the failure, as in vitamin-D int sarcoidosis, hyperparathyroidism, and myelomatosis

DISTURBANCES OF MAGNESIUM CONTENT OF THE B

Hypermagnesæmia occurs occasionally in renal fail when the intake of the ion is particularly high and rate of excretion low It is usually the sequel to ad tration of magnesium sulphate as an aperient T

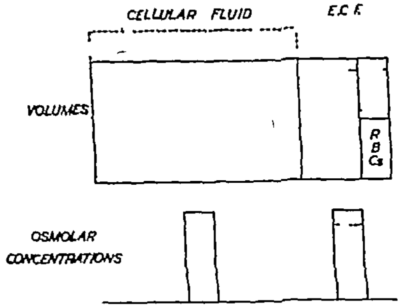

Fig 5—Cellular overhydration due to decreased extracellular osmolarity

For comment, see text

clinical effect is the same as the administration of a sedative

Magnesium deficiency is found in the early diuretic phase of acute tubular necrosis, but no clinical picture can yet be attributed to it with certainty

DISTURBANCES OF WATER BALANCE

Last among the known disturbances considered are those affecting water balance These are less well known than the others but of greater importance. They probably cause more deaths than all the others combined

Four types may be recognised—cellular overhydration and underhydration and extracellular overhydration and underhydration—and various combinations of these occur

Cellular Overhydration

Cellular overhydration is a common disturbance It occurs especially in the anurias but it may also be seen in chronic renal failure and in certain types of circulatory renal insufficiency The main factors determining its occurrence are (1) a discrepancy between intake and output of water and (2) the osmotic pressure of the body fluids, which is in turn affected by intake and output of electrolyte

The following examples illustrate how these factors operate:

The fluid intake or the rate of production of water from fat, carbohydrate and protein may exceed the rate of fluid loss from the body, leading to an expansion of all body water compartments and a fall in the concentration of their solutes (fig 3) This is commonly seen in the anurias. When the rate of water intake is very high, patients with chronic renal failure may develop cellular overhydration by this same mechanism

I once had a patient with chronic renal failure who unwisely drank 5 litres of water in about an hour He became nauseated and confused very soon afterwards. His volume of urine increased sharply for about half an hour and then decreased to oliguric levels. He died about four hours later

Funck Brentano (1953) has studied this phenomenon of oliguria in cellular overhydration and believes that swelling of renal cells may account for the deterioration in renal function. Even if this explanation is incorrect, it is important to recognise that cellular overhydration is dangerous for this reason as well as for others.

In treating anuric patients it seems at first sight that by keeping the total body weight constant we could avoid overhydration. Hamburger and Mathé (1954) point out that this is not so, because the katabolism of fat and tissue releases water which enters the fluid compartments of the body and so alters the ratio of dry weight to total weight. Each gramme of fat burnt releases about 1·25 ml. of water The mechanism is illustrated in fig 4

The osmolarity of extracellular fluid may fall and allow water to diffuse into the cells (fig 5) Na and Cl are the commonest extracellular ions and contribute most of the osmotic pressure of extracellular fluid If for any reason the concentration of these ions, especially Na ion, is low, the osmolarity of the extracellular fluid decreases, and water tends to move along an osmotic gradient into the cells, until osmotic equilibrium has been regained

The sodium content of the body may be low because of reduced intake, as in patients on low-salt diets, but the usual cause is undue loss of the ion. This may take place through diarrhœa, vomiting, or sweating, or, most important, through the kidney This renal loss of Na is of special importance because it occurs very commonly in both acute renal failure (Bull et al. 1950) and chronic renal failure (Nickel et al 1953) Fig 6 shows how extensive the loss may be in acute tubular necrosis and fig 7 in chronic renal failure.

In my experience, this uncontrolled salt loss is invariable in the early diuretic phase of acute tubular necrosis. In chronic renal disease it is also very common I believe that it occurs to some extent in nearly 50% of patients, although it is rare in the gross form described by Thorn et al (1944) which simulates Addison's disease.

Mechanism of salt wasting.—There are two main reasons for loss of salt in renal disease.

(1) If, in a normal person, we induce an osmotic diuresis—e.g., by injection of mannitol or by ingestion of urea—the volume of urine increases and with it the excretion of Na (figs 8 and 9)

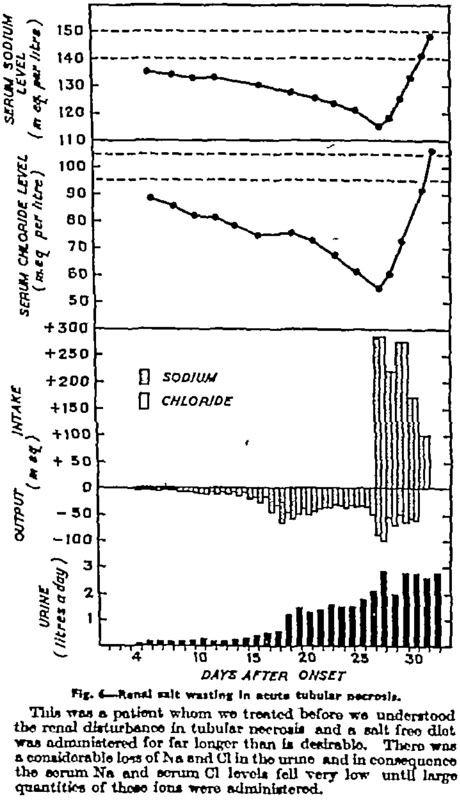

Fig. 6—Renal salt wasting in acute tubular necrosis.

This was a patient whom we treated before we understood the renal disturbance in tubular necrosis and a salt free diet was administered for far longer than is desirable. There was a considerable loss of Na and Cl in the urine and in consequence the serum Na and serum Cl levels fell very low until large quantities of these ions were administered.

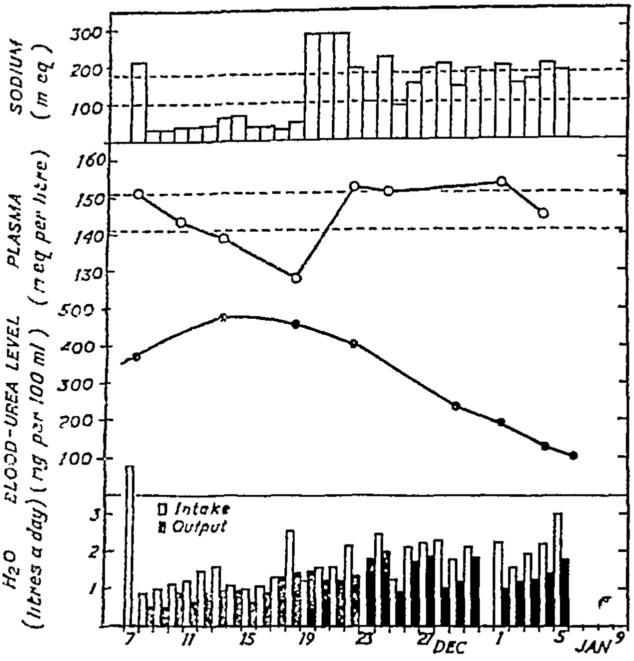

Fig 7—Salt wasting in a patient with chronic renal failure.

The figure shows sodium wasting in a patient with chronic renal failure Between Dec 7 and 19 the serum sodium level fell well below the normal range despite an intake of sodium of about 50 m eq a day, equivalent to an intake of about 3 g of salt per day A normal person can maintain salt balance on an intake of a tenth of this To maintain balance a large intake of sodium (about 200 m eq per day) was required

---

It has been shown by Rapoport et al (1949) that the change in excretion of Na and H_2O can be directly correlated with the excreted load—i e, the number of mols of solute excreted in the urine—and is independent of the type of solute

Where the number of nephrons is reduced and the excreted load kept constant, the load per nephron is increased, and this has the same effect as a high over-all load in a normal person

Thus, a patient with renal disease, in balance on an ordinary diet, excretes per minute the same amount of urea and other osmotically active solutes as a normal person, but through fewer nephrons The excreted load per nephron is therefore higher than normal, and these patients are, in fact, in a constant state of osmotic diuresis They excrete more Na than they should, and have a constant polyuria. As Fremont-Smith et al (1931), Homer Smith (1951), and Platt (1950) point out, this osmotic diuresis may also explain the isosthenuria of renal failure, for the following reason

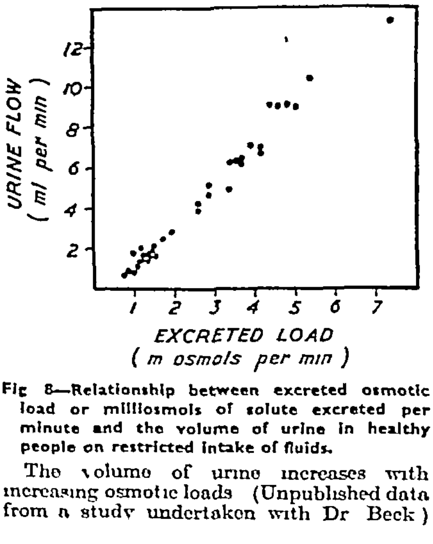

Fig 8—Relationship between excreted osmotic load or milliosmols of solute excreted per minute and the volume of urine in healthy people on restricted intake of fluids.

The volume of urine increases with increasing osmotic loads (Unpublished data from a study undertaken with Dr Beck)

If we administer an osmotic load to a hydropenic patient excreting concentrated u we find, in addition to a diuresis, a decrease in the of the urine towards that of the plasma, which is about 3 milliosmols per litre Similarly, an osmotic load in an o hydrated patient passing dilute urine increases the osmolari of the urine (fig 10)

As the osmolarity and the specific gravity of the urine approximately correlated, it is easy to see how an osmotic load, even in a normal person, contracts the possi range of specific gravity of the urine, until eventually becomes fixed at 1 010, or 310 milliosmols per litre In re disease the same effect is brought about by a reduction in number of nephrons

(2) Another reason for the Na loss in renal failure i that, where the base-sparing capacity of the kidney reduced, as in renal failure, fixed base, particularly Na, is excreted in increased amounts when the patient is acidotic As most diets are acidifying, this becomes a factor in increasing the drain of Na from the body Isolated abnormalities of the tubules exist in which it is the only cause of Na wasting

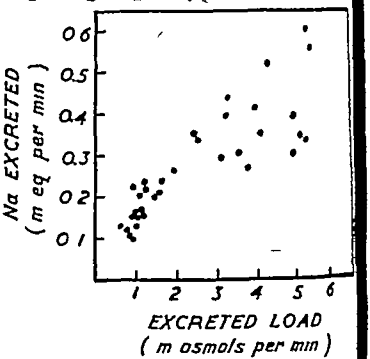

Fig 9—Relationship between excreted osmo tic load or milliosmols of solute excre per minute and the urinary excretion Na by normal persons

The excretion of Na increases wi increasing osmotic load (Unpublish data from a study undertaken wi Dr Beck)

Clinical recognition of cellular overhydration—The presence of cellular overhydration may be suspected when the history and examination suggest any of the circumstanc mentioned The symptoms and signs of cellular over hydration (modified from Hamburger et al 1950) ar as follows

Clinical

- Anorexia
- Nausea
- Vomiting
- Lassitude
- Stupor and confusion
- Changes of mood
- Coma
- Epileptiform convulsions
- Muscle cramps (unusual)

Laboratory

- Low serum Na level
- Low mean corpuscular Hb concentration and high corpuscular volume

Note that the first five of these may aggravate t condition by diminishing Na intake or by increasing loss

Laboratory tests which assist the diagnosis include t determination of the plasma Na level, which is low the mean corpuscular hæmoglobin concentration, is low , and the mean corpuscular volume, which is

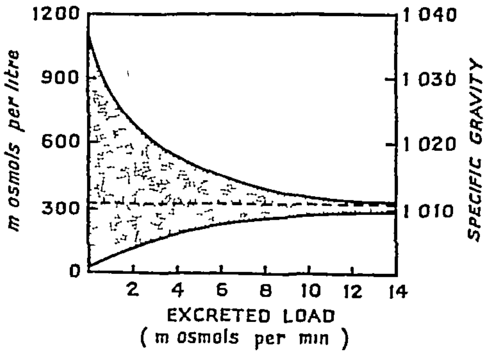

Fig 10—Effect of osmotic load on concentration and dilution of

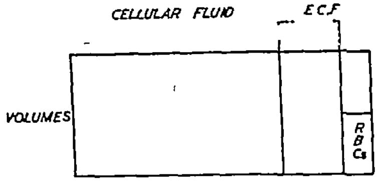

g 11—Expansion of extracellular space without increase in volume of plasma.

ecause the red cells, in common with other body cells, re overhydrated

A low value for the plasma Na level is not patho nomonic of cellular overhydration, and can occur with ormal cell hydration in nephrosis and other protein eficiency states.

xtracellular Overhydration

Two varieties can be distinguished

Pure expansion of extracellular space without increase n volume of the plasma (fig 11)—e.g., nephrosis Here he symptoms and signs are those of the œdema alone

Expansion of extracellular space with increase in plasma volume (fig 12)—This is more serious. It occurs in ongestive heart-failure, following excessive administra ion of adrenocortical hormones and in renal disease when water and salt are given in excess of the ability of the idney to excrete them A good example of the last type is in anuric patients given excessive quantities of intra venous saline solution or of sodium sulphate. The symptoms and signs are those of congestive cardiac failure Here it should be pointed out that the heart failure itself reduces renal function further and lessens the ability of the kidney to correct the imbalance.

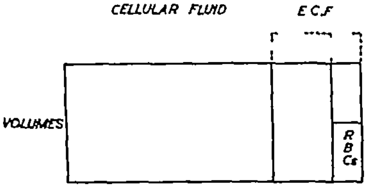

Fig. 12—Expansion of extracellular space with increase in volume of plasma.

The condition is recognised from the history and physical examination, with special reference to observa tion of the venous pressure The specific gravity of the plasma is usually low

Cellular Underhydration

Cellular underhydration occurs when the rate of water intake is less than the rate of loss by all routes. Here cellular and extracellular underhydration usually coexist. In these cases the extent of the underhydration can be roughly assessed by measuring the specific gravity of the plasma. The reason for this is shown in fig 13 Phillips (1950) has shown that for each 0·001 rise in the specific gravity of the plasma above the normal 1 027, the patient lacks about 200 ml. of fluid

Less commonly cellular underhydration may occur with either normal hydration or overhydration of the extracellular space Here the mechanism is a primary retention of Na and an osmotic movement of water towards the extracellular ions takes place (fig 14) The usual cause of this type of cellular underhydration is the administration of isotonic Na containing fluids to ydrated patients without additional water Water is t in the breath and through the skin and in certain cumstances through the kidney also with the result that the extracellular fluid becomes hypertonic and water moves from the cells.

If the patient is conscious he complains of thirst Later he becomes stuporose or comatose, and often he develops coarse twitchings rather like those seen in hepatic coma Particularly in children, the body temperature may rise sometimes to as high as 103°F The tongue is small, and in a severe case the muscles have a curious doughy feel which may be mistaken for œdema. The finding of a high plasma Na level confirms the diagnosis

Extracellular Underhydration

Extracellular underhydration may occur as a part of general under hydration or as an isolated manifestation In the latter case it is due to a deficiency of extracellular ions.

The clinical picture with sunken facies lax skin, diminished eyeball tension and later, hypotension and rapid pulse is well known The measurement of the specific gravity of the plasma is very valuable in assessing the extent of the water lack.

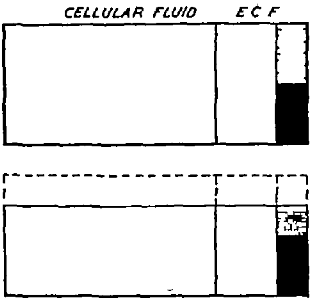

Fig 13—Cellular and extracellular underhydration (illustrating rise in plasma-protein concentration)

The dots represent protein molecules. Their concentration rises as water is lost from the plasma. The specific gravity of protein free plasma is about 1 008, and that of normal whole blood 1 027 The difference between these two figures is due to serum proteins. Therefore the specific gravity of plasma can be used to measure the plasma protein level.

It is particularly important to recognise extracellular underhydration because it leads to peripheral circulatory failure with associated circulatory renal insufficiency (extrarenal uræmia) This secondary reduction in renal function may cause many of the other uræmic pictures already dealt with

Uræmic Manifestations whose Mechanisms are Unknown

Anæmia—Chronic azotæmia is almost always accom panied by a normocytic normochromic anæmia, and the severity of the anæmia parallels that of the azotæmia.

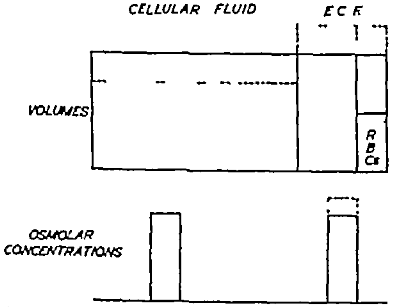

Fig 14—Cellular underhydration due to hypertonicity of extracellular fluid.

For comment see text.

The mechanism is unknown, except that the anæmia is usually of the dyshæmopoietic type but occasionally has a hæmolytic element It does not respond to the usual hæmatinics

Anæmia is important because it may cause cardiac failure or circulatory renal insufficiency, both of which make the azotæmia worse

Purpura is common in terminal uræmic states Again, the mechanism is unknown

Intestinal disturbances—Stomatitis, gastritis, enteritis, and colitis may occur in severe renal failure These may be produced by high concentrations of ammonia formed from urea by the urease normally present in the gastric mucosa and in intestinal organisms

Pericarditis occurs in terminal renal failure No completely satisfactory explanation has been given

Infection is very common in terminal uræmic states and plays an important part in causing death in many patients with renal failure (table I) Such patients appear to be particularly liable to infection, especially bronchopneumonia In some this tendency is obviously explained by a disturbed level of consciousness, but in others there is no obvious cause, and one wonders whether there is some disturbance in the immunity mechanism in the lung Possibly the curious "uræmic œdema" of the lung described by Doniach (1947) acts as a precipitating factor The usual infecting organism is the staphylococcus, and at least in the last few years this has been penicillin resistant in many cases

TABLE I—CAUSES OF DEATH IN RENAL FAILURE

Disease	Infection	Other causes
Acute renal failure * (mostly acute tubular necrosis)	24 (63%)	14
Chronic renal failure †	13 (35%)	24

* Mostly patients seen with Dr Joekes and Dr Lowe

† From necropsy records of department of pathology, Belfast. Figures kindly supplied by Professor Biggart.

Infections are important in two ways they may prove fatal because of the toxæmia, but also they may increase metabolism and so flood the system with end-products of tissue breakdown, disturbing an already precarious state of water and electrolyte balance Release of potassium from cells as a result of this katabolism is of special importance in the anurias

Thus in the management of renal failure the prevention and treatment of infection and its consequences require careful attention

Conclusions

Combinations of the disturbances described account for most of the clinical pictures met with in renal failure, but I do not wish to leave the impression that they account for all Some patients may be comatose or even die without our being able to detect, by our present techniques, any causal chemical abnormality Conversely, other patients may show quite gross deviations from the normal blood chemistry, with no clinical abnormality

(*To be concluded*)

"The theory of the modern kitchen and the labour-saving device is that it suddenly launched women on to new seas of opportunity, oceans of rippling, sun flecked leisure And there is no doubt at all that it has absorbed, via the electric motor, a great deal of absurd drudgery which no human being ought to have to do at all But it now appears that women still have to decide to use wisely the leisure they have gained And the Senate report seems to say that there is still no electronic escape from the time that should be given to children, and no substitute for the maybe seemingly lazy contact with one's own children It is not the male tyrant any longer, or the educator, or the intellectual who insists that woman's place is in the home It is now, heaven help us, the psychiatrist"—ALISTAIR COOKE, *Listener*, March 31, 1955, p 561

THE DIFFICULT APPENDIX

PHYSIOLOGY APPLIED TO DIAGNOSIS

J A. KERR

B Sc Birm, F R C S

CONSULTANT SURGEON, HASTINGS GROUP OF HOSPITALS

TWENTY-FIVE years ago, as a locum in general, I was called to a young girl who complained of intermittent abdominal pain and vomiting Daily observation failed to elicit any physical signs After five days another practitioner was called in, but too late The patient had general peritonitis and died shortly after admission to hospital.

Later, when in general practice on my own account in the country, I saw a young man who had had sudden violent abdominal pain and vomiting There was no abdominal rigidity nor tenderness, but during the course of the day localised deep tenderness in the right iliac fossa was discovered There was no pyrexia and the pulse-rate was 60 A colleague who was called in agreed with my belated diagnosis A backward-lying perforated appendix was removed and the patient recovered.

A few months later, in hospital practice, I saw a boy with no abdominal signs, no pain, no pyrexia, and no rise in pulse rate He appeared to be perfectly well and I was inclined to send him back to his doctor, whose letter recorded abdominal pain and tenderness On the strength of this, however, the boy was admitted Pain and tenderness soon recurred, and three hours after admission a gangrenous appendix was removed and he recovered

Diagnosis

The final diagnosis of appendicitis must be based on the correlation of the pathological changes with the clinical picture—a picture built up from the physical signs and the significant details in the history. The notes made at the time of examination must be continued at the operation by recording the position and external appearance of the appendix, surrounding organs, and peritoneal cavity A specimen of any peritoneal fluid is taken for microscopy, culture, and tests of sensitivity to antibiotics The appendix is slit from end to end and its walls, mucosa, and contents examined A watchmaker's eyeglass may reveal a fascinating vascular pattern and differentiate post-inflammatory petechiæ from vascular flares

The First Attack

The first attack is ushered in by diffuse central or transverse umbilical pain, of gradual onset and steadily increasing severity, and nausea This pain is visceral and is referred along the 10th dorsal nerves, the excitable state of which is shown by Ligat's sign—that is, pain on pinching and drawing away the skin and subcutaneous tissue on one side or the other below the umbilicus Later, abnormal stimulation of the parietal peritoneum may accentuate the spinal reflex on the right side, thus giving the sign as Ligat described it Pain may be epigastric from pylorospasm, or hypogastric from spasm of the sigmoid colon, with loss of appetite, nausea, and vomiting on the one hand and constipation on the other

The inflammation may resolve in a few days and the appendix return apparently to normal It may leave a condition of fibrosis, either diffuse in the walls, or around certain lymph follicles, leading to sunken red petechiæ, which turn purple within a year of the attack, and in course of years may become white, giving a appearance The red hæmorrhagic flares caused by application of forceps to the meso appendix are sunken Recurrent attacks of catarrh presumably the condition of diffuse fibrosis of the wall with mucosa and progressive obliteration of the lumen the tip backwards, leading eventually to a natural On the other hand, fibrosis may lead to localised ig of the lumen with incomplete emptying and stercolith ormation with retention

The first attack may hardly have been noticed by the atient or may have been forgotten Subsequent attacks ay be similar to the first, or may start with pain in the ight lower quadrant, or with nausea or mid abdominal olic due to appendicular obstruction either from œdema omplicating fibrosis of the walls or from impaction of stercolith Continuing obstruction of the lumen is ollowed by distension and gangrene of the mucosa, with pread of the infection through the wall in the case of tricture or local ischæmic necrosis in the case of an mpacted stercolith, which may ulcerate through the vall and into the peritoneal cavity Gangrene or perfora ion gives relief of the visceral pain and disappearance f Ligat's sign Peritonitis may then be diffuse, or imited to a local pocket or to a focal abscess by a cap f greater omentum In the rare case where obstruction s not complicated by infection or gangrene, a mucocele f the appendix is formed

The Position of the Appendix

The effect of the progress of inflammation from the mucosa through the wall to the serous surface depends on the site of the appendix and its relation to surrounding viscera and parietal peritoneum. Irritation is caused by direct contact with the inflamed appendix and by centrifugal spread of irritation in the peritoneal cavity The vehicle of this irritation which may be likened to an odour, is presumably peritoneal fluid exuded from the serosa of the appendix

Should the appendix be lying untethered in what is considered to be the normal position, with maximum tenderness deep to McBurney's point, this irritation has access to the parietal peritoneum, pain is referred by spinal reflex to the right lower quadrant and it is aggravated by spinal or respiratory movements or by any considerable or sudden movement of the abdominal wall with consequent voluntary limitation of these movements and involuntary protective increase in muscle tone of the parietes by spinal reflex Sudden release of pressure gives rebound tenderness and referred tenderness particularly on rebound can be demonstrated by pressure elsewhere Some degree of local ileus is shown by a silent abdomen constipation, and fœtor of the breath Parietal irritation is also accompanied by rise in temperature and pulse rate

The inflamed *paracæcal appendix* gives tenderness on pressure in the outer part of the right loin, and anteriorly $1^{1}/_{2}$ in. above and external to McBurney's point

The rarer *inverted cæcum* gives tenderness over the gall bladder to which the appendix is then adjacent and the diagnosis is made easier by re-examination after hyperextension of the lumbar spine by means of a pillow in the small of the back to separate these organs.

The *retrocæcal appendix* can be considered to be extraperitoneal There is irritation of the cæcum and adjacent muscles with excess of flatus or early transient true diarrhœa, and tenderness in the loin below the right kidney Bimanual examination between the loin and flank may suggest renal tenderness but tenderness is also continued caudally and is not localised to the kidney Direct irritation of the ureter may produce some increase in frequency of micturition which is not, however so marked as in urinary infection It must be realised that urinary infection and appendicitis may co-exist and that removal of the appendix may clear the urinary infection Protective flexion at the right hip joint is produced by psoas irritation there is pain on walking and passive extension of the right hip gives pain in the right lower quadrant or groin (*psoas-stretching test*)

The inflamed *pelvic appendix* may irritate the bladder giving rise to hypogastric pain relieved by micturition the rectum with a discharge of mucus (a spurious diarrhœa) or the lumbosacral cord giving pain referred down the lower limb These symptoms are relieved by appendicectomy The sign of an inflamed pelvic appendix however, is high right posterolateral tenderness and fullness at the finger tip on rectal examination, with pain referred to the abdomen This may be confirmed by pain on passive internal rotation of the right hip in flexion (obturator internus stretching test) Tenderness may also be elicited by deep localised pressure $1^{1}/_{2}$ in below and internal to McBurney's point, this however, may be absent, and I have not commonly elicited the obturator test

The difficult case for diagnosis is the inflamed *tethered retro mesenteric appendix*, which gives none of these parietal signs The only organ directly irritated is the lower ileum with its mesentery The appendix is connected by its meso appendix with the left leaf of the mesentery of the ileum Should this meso-appendix be long the appendix is mobile and is free to irritate the parietal peritoneum by direct contact or centrifugal spread, with local pain and the generally recognised signs of the mobile inflamed appendix.

There is an anatomical variation, however, in which the meso appendix is short near the tip allowing little or no movement between the appendix and the deep surface of the mesentery of the ileum, in which in fact it may be embedded This can effectively enclose the inflamed appendix without help from the greater omentum, beneath the mesentery of the ileum, deep in the coils of small gut, local dilatation of which protects the appendix from the tenderness of ordinary pressure and the parietal peritoneum from irritation Infection is free to spread deep in the left iliac fossa and down to the pelvis still enclosed in mesentery and gut

Pain is not localised to the right lower quadrant There is no muscular rigidity nor increase in muscular tone, no tenderness on light pressure nor guarding no rise in temperature nor marked rise in pulse rate The bowel is not silent, and through absence of constipation there is no fœtor of the breath and the tongue is clean The patient does not look ill, has periods without pain, and may go to sleep

Tenderness if present in these cases, can only be elicited by localised deep pressure with one finger, $1^{1}/_{2}$ in above and internal to McBurney's point—that is, midway between McBurney's point and the umbilicus—and from this point in a vertical line upwards 2 in long with its centre 1 in. to the right of the umbilicus. This deep pressure may produce guarding and tenderness may be more marked on rebound

The inflamed posteriorly fixed appendix is distinguished by the absence of those parietal signs which are found in a mobile organ, and the usual quiet abdomen with constipation is replaced by symptoms of local activity of the bowel the retrocæcal appendix by excess of flatus or true diarrhœa at the onset; the pelvic appendix by spurious diarrhœa; and the tethered retromesenteric appendix by symptoms to be described below

Bowel Symptoms

The tendency to stasis from localised paralytic ileus is countered by direct irritation of the lower ileum. This is revealed by the auscultation of intermittent bursts of squirting borborygmi which may sometimes be continuous, but there is no diarrhœa The patient may say he has diarrhœa, but careful questioning will elicit the fact that the motions are frequent and soft but not fluid Not having been subjected to the action of a laxative the bowels are spontaneously opened three or four times in a day with small formed motions, followed by perhaps one or more soft motions which may be green The ileum propels its contents with increased frequency into the cæcum whence progress along the colon is more leisurely enabling some fluid absorption to take place, though progress is somewhat faster than normal These frequent bowel actions are also described in previous attacks and may last for only one day, local ileus then predominating

Rupture, should it occur, is into the retro mesenteric pocket and there is no generalised " burst spread " Pain and hyperæsthesia disappear, and dilated gut cushions the part from tenderness and the parietal peritoneum from irritation There is a latent interval with no physical signs, *comparable with that of gangrenous* intussusception and of gall stone ileus The bowel is in a state of ileus due to sub-ileal peritonitis No flatus or fæces is passed, and auscultation reveals a silent abdomen Later, deep localised bilateral tenderness is found, and within one to three days nausea recurs with some pain, and bowel actions are resumed These take the form of diarrhœa, from external irritation of the distal large bowel (see cases 1, 2, 4, and 5 below) Nausea ceases and *the tongue is clean Distension* is a feature when ileus is accentuated by the taking of a purge (case 4), when bowel action is delayed (case 3), or where peritonitis is prolonged (case 1)

Illustrative Cases

All these patients were seen by consultants, who found some difficulty in diagnosis Each case seems to show the symptoms and signs which can be expected in the various stages *of an acutely inflamed tethered retro*-mesenteric appendix The most serious and complicated cases come first, and the later ones show progressively less serious complications and earlier diagnosis I have indicated in parenthesis what I consider to be the time of perforation of the appendix

Case 1 General Peritonitis, Mesenteric Phlebitis, Portal Pyæmia

A man of 38 was well until a fortnight before admission, when he had abdominal pain which lasted for a few days (*appendix perforated when pain ceased*) A week after the onset he had diarrhœa and vomiting, thought to be due to gastric influenza Three days later, on a Saturday, he felt ill with abdominal pain and vomiting, some distension and constipation Bowels were moved with aperients On the Sunday and Monday the vomiting continued every six hours or so , it was not fæculent, and he passed a little flatus He was admitted to hospital on the Wednesday with a temperature of 97°F, pulse rate 84, and respirations 20 A plain radiograph of the abdomen showed multiple fluid levels

Operation revealed a gangrenous appendix which had caused general peritonitis The abdomen was mopped out as much as possible and closed with drainage tubes in position There was no postoperative vomiting, but the abdomen became distended Two days after the operation, an intravenous drip was set up and gastric aspiration instituted His temperature rose above normal for the first time since admission. He seemed to do fairly well for a time and was able to drink He passed a small amount of flatus and fæces But a fæcal fistula formed at the lower end of the wound, and he became jaundiced Ten days after admission he was very jaundiced and stuporose, and he collapsed and died that evening

This patient apparently harboured diffuse sub-ileal peritonitis for ten days under careful observation, with *no morning or evening pyrexia for a fortnight* Tenderness was absent or slight and transitory, and no rigidity was found Intestinal obstruction threatened after a week The temperature first registered above normal the day following operation The cause of death was mesenteric thrombosis, fæcal fistula, and portal pyæmia

A colleague has told me of a similar case kept under careful observation in hospital before operation, with similar operative findings, the appendix lying backwards and adjacent to the mesentery of the ileum The patient became jaundiced and died

Case 2 Diffuse Peritonitis, Recurrent Abscesses, Fæcal Fistula

Two years before I first saw her, a girl of 23 had had her first attack of abdominal pain, lasting thirty six or forty eight hours , she felt sick and retched, and there was pain and tenderness around the umbilicus A year later she had a similar attack, and then no further trouble She had a three stage thoracoplasty nearly twelve months before I saw her Two days earlier she ate some cooked cheese, which upset her Next day she felt sick with recurrent periumb soreness which came and went, like an occasional kick in stomach *She felt better in the evening (appendix perf* and on the following morning, but she still had c pain In the evening her temperature was 100 4°F (6 P and 101°F (6 30 P M) She had slight pain and very occa nausea She had taken only a little fluid. The bowels had opened and *no flatus had been passed* but she had had enema that afternoon with flatus result and felt better, she vomited once copiously In this attack, there was exce flatulence with eructation and relief There were no urin symptoms and no rigors She had just finished a peri Previous attacks were not remembered to have had relation to periods

At 8 P M the abdomen was slightly distended. Lig sign was absent There was good but even tone of the abdo nal muscles No superficial nor deep tenderness could elicited, and *there* was no rebound sign The abdomen w silent The rectum was almost empty, but a little balloon with some tenderness referred to the hypogastrium Conclu sion " I must diagnose an inflamed backward lying append here "

A *white cell* count showed *21,000 cells* per c.mm. 9 10 P M , obturator internus and psoas stretching tests w both found to be negative She felt quite comfortable a had slept

Next morning I learned she had vomited bile and had pas *two loose stools* with relief There was very slight deep tende ness on either side below the umbilicus The abdomen w still quiet The white cell count was 30,000 (80% polymorph the temperature 99 2°F, and pulse 112 She was admitt to hospital and operated on in the afternoon An acute inflamed appendix, gangrenous and *perforated at the* ba was removed There was a fæcolith lying free in the periton cavity, and much foul fluid The appendix was lying backw behind the ileo cæcal junction There was no stump appendix because of the perforation The hole in the cæc *was oversewn as well as possible, and the abdomen* drain by one tube

She had a difficult time and did not leave hospital un six months later A pelvic abscess developed, which burst an passed per rectum a month after the operation Three wee *later she had a laparotomy* with *aspiration and* drainage of localised extraperitoneal abscess running from the left ili fossa down to the left side of the pelvis and to the right the midline Four days after this operation fæcal mater and flatus discharged from the wound in the left iliac fos Five weeks later the abscess was drained extraperitoneall by inserting sinus forceps through the wound At a secon drainage six days later a drainage tube was inserted well dow into the cavity ' Lipiodol ' injected into the tube showed narrow track the width of the tube extending about 7 towards the head of the left femur, but no definite cavity month later pain recurred in the left iliac region, and th pelvic abscess had re formed, but this drained satisfactorily and the wound became dry She was left with residu induration in the left iliac fossa Subsequent progress w satisfactory

At various times during her illness, pus from the absc grew coliform bacilli, *Staphylococcus aureus*, and proteus A no time were tubercle bacilli or actinomyces found Th organisms found were sensitive to streptomycin and chlor amphenicol She was given two courses of intraveno aureomycin in the first two months of the illness

When I first saw this patient, she was in the late interval of lower-pole retro-ileal peritonitis after perfora tion of her obstructed appendix Apart from raise temperature and pulse-rate, the only sign was recta tenderness referred to the hypogastrium , the white-ce count was raised, however, and the next morning the was very slight deep bilateral abdominal tenderness.

Case 3 Localised Sub ileal and Pelvic Abscess

A woman aged 73 had severe pains low on both sides of th abdomen with swelling of the abdomen and bad headach For about nine months previously she had had high epigastr pain radiating down the front of the abdomen, not apparentl related to meals, but eased by a light breakfast , it was alwa there, a constant burning pain She had always been const pated, more severely in recent months. She passed sma motions followed by a little blood after straining Pain wok her at night

I first saw her five days after the attack of severe pain She had passed no flatus since (*Appendix had perforated and ileus followed.*) She had vomited a little green bile every day Borborygmi were relieved by eructation There had been pain in the vagina for the past two days. Her bowels had not been open since the attack of pain until the day I saw her when they were opened three times with temporary relief the first time soft the second formed the third a good movement Her temperature was 99·6°F and pulse-rate 84 She was emaciated, with pale eyes. The tongue was clean and dry with a few plaques. The abdomen was resonant distended and tender all over with positive rebound sign There was no true rigidity or palpable tumefaction but I found visible coils of gut with quiet squirting borborygmi in the left lower quadrant No peristalsis was seen The rectum was ballooned and tender She was admitted to hospital with a diagnosis of threatened acute intestinal obstruction probably from carcinoma of the lower colon X ray examination of the abdomen showed some distended coils of small bowel. An enema produced flatus and later a small action

At operation two days after admission, pus was found among the coils of small gut with organised exudate and an abscess deep in the pouch of Douglas. A perforated appendix was adherent to the ileum and it was removed but the stump could not be invaginated Adhesions were separated from the lower end of the ileum Postoperative treatment included half hourly aspiration from an indwelling Ryle's tube intravenous fluid and streptomycin. Two days later flatus was passed and loud squirting borborygmi were heard. Ten days after the operation the abdomen was much distended. The bowel was silent and there was very slow slight visible peristalsis The temperature swung to 102°F Pus discharged spontaneously from the lower end, of the wound and the temperature quickly settled. The patient was discharged fit five weeks after the operation

In this case the peritonitis had not spread but localised to form an abscess among the coils of small gut, and the bowel actions were similar to those to be expected, before perforation from irritation of the lower ileum—that is one soft motion and two formed ones (but see case 5)

Case 4 Localised Abscess Commencing Lower pole Peritonitis

A man aged 67 was admitted to hospital with a diagnosis of subacute intestinal obstruction. His doctor wrote: Three days ago this patient had some indigestion and went off his food Prior to this he had been in great fettle Next day he gave himself a large purge and during the afternoon was smitten with violent abdominal pain. He tried to get to the lavatory but collapsed en route I found him writhing with colic His abdomen was much distended and tight as a drum. Knowing that he has a double rupture I went for his inguinal rings. I thought that I felt a tense swelling high up in the left inguinal canal Before I could be sure he rolled over suddenly and started violent retching, bringing up a little altered blood. When I again examined him there was no swelling in the canal (if there ever had been) and his pain became rapidly better and gr $^{1}/_{144}$ of atropine completed the job (*Appendix perforated.*) I saw him yesterday and he was much better Today he is not so well. He is afebrile with a pulse of 80 and his tongue is dry His lower abdomen is distended His rectum is empty and feels normal He is nauseated but has not been sick He has absolutely no appetite but very little abdominal pain. He has passed several small watery stools but no flatus.

In hospital his temperature was 99°F and pulse rate 84 His eyes were dull and tongue furred brown and dry The abdomen was distended and resonant There was no true rigidity but it had a doughy feel. Ligat's sign was negative. There was slight temporary increased muscle tone in the right lower quadrant. Tinkling sounds were auscultated There was a definite positive rebound sign in the right and left lower quadrants but no referred tenderness. There was slight localised deep tenderness (*a*) 2 in above the pubic tubercle on the left and (*b*) $1^{1}/_{2}$ in. internal to McBurney's point on the right 1 in from the midline and 1 in below the umbilicus. Rectal examination revealed no abnormality A diagnosis of retro ileal appendicitis with lower pole peritonitis was made.

On opening the abdomen red coils of gut were seen but there was no free fluid A backward lying appendix swollen gangrenous, and perforated at the tip was lying in a small abscess cavity with an ounce of thick pus among the coils of small gut A collection of reddish brown fluid was found in the left iliac fossa with a similar collection deep in the pelvis The appendix was removed and the fluid mopped out The upper abdomen was explored with a swab and nothing was found The abscess cavity in the right iliac fossa and the pelvis were both drained Pus from the retro ileal abscess gave a growth of lactose fermenting coliforms. He was given streptomycin (1 g twice daily intramuscularly) with intravenous saline and hourly aspiration of the stomach Next day he was very thirsty and there were no bowel sounds. A week later he looked and felt much better and was on a full diet. His bowels were working his fluid state was good and the abdomen soft Subsequent progress was satisfactory

In this case (and in cases 1 and 2) the diarrhœa was watery and quite transient and, by analogy with case 3, presumably due to direct external irritation of the distal colon and rectum from the spreading peritonitis. This might have remained localised but for the purge which presumably caused early spread of inflammation to the left iliac fossa and to the pelvis, with slight temporary increase in parietal muscle tone, localised bilateral deep tenderness, both direct and on rebound, and distension The temperature rose only slightly above normal just before operation presumably from pus under pressure with pulse rate 84 There was no rigidity After operation, some degree of paralytic ileus persisted for a week. Case 3 with an abscess deep in the coils of small gut showed similar signs and postoperative course

Case 5 Localised Abscess Small-gut Obstruction

A fortnight before I saw her a woman of over 70 had had vomiting and diarrhœa. She took to her bed and the vomiting ceased (*appendix perforated*) and later the diarrhœa stopped too The day before I saw her she took food but later the vomiting recurred with acute abdominal colic Her bowels were open once One of her dogs at the time had symptoms of gastro-enteritis.

We found her temperature 96°F and pulse rate 75 The tongue was clean moist, and red She was having recurrent attacks of supra-umbilical pain. There was a firm or hard tender intra abdominal swelling deep to McBurney's point It was not freely mobile Some borborygmi were heard Rectal examination revealed a fixed cervix and a considerable amount of soft fæces, The vomit was brown and offensive

The patient said that forty years ago she had had a similar pain with gastritis and dysentery recurring one year ago for two or three days. She felt that if she could get her bowels open she would be better She was admitted to hospital and an enema gave a fair result of formed fæces with flatus. The vomiting continued We found shifting dullness in the flanks A diagnosis of acute lower small gut obstruction was made

At operation we drained a fibrotic appendix abscess causing small gut obstruction by adhesions. These were divided leaving some narrowing of the lower ileum. The appendix was removed and a side to-side anastomosis of the lower ileum was constructed A tear in the cæcum was repaired Postoperative progress was satisfactory

Pus from the appendix abscess showed numerous gram negative bacilli and a fair number of gram positive cocci. Culture grew lactose fermenting coliform bacilli and staphylococci overgrown by proteus.

This case, though with a similar localised abscess to case 3 showed persistent diarrhœa for a fortnight This may have been due to enteritis secondary to the small gut obstruction which became acute or the patient may have suffered from the same infection as her dog

Case 6 Gangrenous Appendix

A middle-aged woman was seen in consultation. Three years ago she had had infective hepatitis with severe jaundice for some weeks, and she had had irregular indigestion since then At 2 P.M on the previous day a steady constant stomach ache began but she did not vomit She passed three motions up to 9 P M which were not loose Her temperature and pulse were normal. The tongue was dirty She was seen by a colleague who found generalised abdominal tenderness a little more on the right than on the left. There was no guarding nor rebound tenderness, but she did not like deep pressure Vaginal examination revealed no abnormality and no referred pain. The small-gut was thought to be the seat of the trouble The pain continued all night and the next morning the temperature was 99°F and pulse 96. She vomited a small amount at 10 A M , and passed a motion which was green and black She was now a little more tender all over There was no distension but a little indefinite guarding She had had nothing to eat since the onset of the pain, and a morning cup of tea was recently vomited

When I saw her the tongue was furred, greenish, and moist The abdomen moved with respiration with a catch of severe pain on coughing There was no rigidity or tumefaction She had generalised abdominal tenderness with much rebound tenderness in the right iliac fossa, but no particular pressure tenderness except in the right iliac fossa, maximum at McBurney s point and towards the umbilicus The abdomen was silent Ligat's sign was not elicited, and the obturator-internus test negative Passive hyperextension of the right hip referred pain to the abdomen

Operation revealed an acutely inflamed, green, distended retro mesenteric appendix with white external exudate This was removed and the abdomen closed without drainage Convalescence was uneventful

The appendix lumen contained liquid fæces The mucosa was thin and red with small black patches A fæcal concretion was wedged in the proximal end.

Case 7 Acutely Inflamed Appendix

A child of 7 was admitted after three days' intermittent abdominal pain On the day it began her bowels were moved three times At 4 P M on the day of admission she vomited. Her temperature was then subnormal and pulse rate 88 No tenderness was found in the abdomen or rectum, but scybala were felt Pain and vomiting continued, the pain was mostly around the umbilicus The pulse rate rose to 120 The only abnormal sign which had been elicited was a rising pulse-rate, and on this she was sent to hospital

On admission at 10 40 P.M her temperature was 100°F, and pulse 140 There was guarding on the right side, but she was not particularly tender I saw her at 11 25 P M , when there was good tone of the abdominal muscles, slightly increased in the right lower quadrant, but no tenderness A mobile tumour as big as a hazel nut and like a gland was felt in the right iliac fossa Continuous borborygmi were auscultated Rectal examination revealed tenderness mainly on the right, with pain referred to the umbilicus There was no spontaneous pain

I was uneasily inclined to observe the case as one of gastro-enteritis, but perusal of the case sheet and confident prompting of a wise house surgeon led to immediate operation Through a midline incision a low lying retro ileal appendix with omentum adherent to the bulbous tip was removed There was no free fluid The bulbous tip was found to contain pus, and the mucosa was black Proximal fibrosis closed the cavity Progress was satisfactory

Conclusions

The inflamed tethered retro-mesenteric appendix is deep in the centre of the abdomen, and the symptoms and signs to which it gives rise are entirely visceral from inflammation of the appendix itself and from irritation of the adjacent lower ileum, producing frequent formed motions Tenderness is to be elicited only by localised deep pressure at the sub-ileal point, which in the adult is $1^1/_2$ in from the umbilicus to the right and below, and by pressure in a vertical line extending upwards from this point to 1 in above the level of the umbilicus

Perforation is accompanied by cessation of symptoms and disappearance of subcuticular hyperæsthesia, and peritonitis spreads deep in the left iliac fossa and down to the pelvis, irritating the distal large bowel and giving rise to watery diarrhœa There may then be bilateral deep suprapubic and rectal tenderness

There is no irritation of the parietal peritoneum or greater omentum (and consequently no rise in temperature nor increase in pulse rate of more than 20 beats per minute), no increase in parietal muscular tone, no rigidity, no constipation, and no fœtor of the breath, and the tongue is clean

In the case of the mobile untethered inflamed appendix, nervous reflex from irritation of the parietal peritoneum is the cause of (1) pain in the right lower quadrant, (2) decreased mobility of the abdominal wall, (3) the presence of Ligat's sign on the right side, (4) local increase of muscular tone and rigidity, (5) tend light pressure, (6) referred tenderness, (7) cont of general intestinal stasis with quiet abdomen fœtor of the breath, (8) pyrexia, (9) a rise in pulse of more than 20 beats per minute, (10) con malaise, and (11) sleeplessness

None of these signs is present in the tethered mesenteric appendix, even after rupture with Pus contained under pressure, however, may pyrexia The absence of tenderness to ordinary palpati is explained by localised distension of the lower ileu which can be shown by plain X-ray examination, a by the inaccessibility to pelvic examination when th appendix is both high and unruptured The peritoni can spread quietly *among the coils of small gut* down to the pelvis because the containing power of th greater omentum is elsewhere

Inflammation in the mobile appendix and in th tethered retro mesenteric appendix must be regard *as two different diseases affecting different parts* of th abdominal cavity which are separated by the mesent of the ileum The one has access to the parietal peritone and the general peritoneal cavity, the other is shut behind the mesentery and may spread to the left down to the pelvis, but it may give rise to one upp abdominal complication—mesenteric phlebitis and port pyæmia The symptoms of retro mesenteric appendici are entirely visceral

Summary

The symptoms and signs of the various stages of acu inflammation of the tethered retro-mesenteric appendi are analysed and correlated with the pathological chang

The clinical picture is entirely different from that the inflamed untethered mobile appendix, apart fro the onset of the first attack in the latter before th parietal peritoneum has been irritated The physiologic cause of this difference is indicated

The symptoms and signs of the tethered retro mese teric inflamed appendix *give a changing* picture whi suggests in turn both gastro enteritis and intestin obstruction but is typical of neither Their very pecul arity and alternations, however, paint a clinical pictu of intestinal paralysis interrupted by bursts of ove *activity which do not appear to be adequately reflecte* in the bowel actions This is typical of the condition its various stages

I have regarded McBurney's point as $^1/_2$ in below th midpoint of the line joining the umbilicus to the righ *anterior superior iliac spine*

I wish to thank my colleagues of the Hastings group fo their coöperation. The surgeons have been extremely helpful and my particular interest in the condition was first arous by Dr A F W Hall *The Early Diagnosis of the Acute Abdomen* by Sir Zachary Cope has been worth its weight in gold

IRON-DEFICIENCY ANÆMIA IN PREGNANCY

P B B GATENBY

VISITING PHYSICIAN, ROTUNDA HOSPITAL , HONORAR
PHYSICIAN, DR STEEVENS' HOSPITAL, DUBLIN

E W LILLIE *
M D Dubl
LATE RESEARCH FELLOW, ROTUNDA HOSPITAL

OUR investigation of the anæmias of pregnanc undertaken at the Rotunda Hospital, Dublin, wi Dr H C Moore, has already been published (Lillie et al 1954, Moore et al 1955) Here we deal with the case of iron deficiency studied at that time

---

* In receipt of a grant from the Medical Research Council of Ir

Methods

Blood was taken, for hæmoglobin and hæmatocrit estimation, from every woman *on her first attendance* at the antenatal clinic. At first all women with hæmoglobin below 10 g per 100 ml. were referred to a special anæmia clinic, but the numbers were such that this arrangement had to be revised, and for most of the year only women with hæmoglobin below 9 g were directed to the special clinic

At this clinic the history and examination were noted on a special form Spontaneous symptoms were recorded, and each patient was questioned about personal symptoms, diet and past history Every patient was examined in a similar fashion A particular note was taken of her general appearance the state of the finger nails, and the colour of the tongue and conjunctivæ The heart lungs, and reflexes were examined in all cases. The clinical signs were recorded always by the same observer (P B B G) to avoid error

TABLE I—MONTHLY INCIDENCE OF ANÆMIA IN PREGNANCY

Month	No of pregnancies	No with Hb less than 10 g per 100 ml	No with Hb less than 9 g per 100 ml.
January	389	129 (33%)	54 (14%)
February	428	124 (29%)	54 (13%)
March	358	95 (24%)	40 (10%)
April	312	74 (24%)	36 (12%)
May	370	97 (26%)	39 (11%)
June	356	107 (30%)	32 (9%)
July	348	79 (23%)	25 (7%)
August	379	60 (16%)	20 (5%)
September	363	56 (15%)	14 (4%)
October	383	96 (25%)	33 (9%)
November	340	55 (16%)	19 (6%)
December	237	55 (23%)	23 (10%)
Total	4314	1027 (24%)	389 (9%)

Iron by mouth was prescribed and each patient was seen regularly to make sure that she was taking the drug as ordered. Her blood was examined every four weeks, and she was followed through pregnancy to term. Women who did not respond to oral iron were treated with intravenous iron and, if this did not increase their hæmoglobin their sternal marrow was examined.

Prevalence and Grades of Anæmia

Of 4314 patients 1027 had a hæmoglobin value of less than 10 g per 100 ml If the standard of 10 g be accepted as the lowest value which can be regarded as due to hydræmia (Dieckmann and Wegner 1934), there were 1027 cases of anæmia among the first attendances at the antenatal clinic in the year (23 8% of the pregnant women attending the hospital) Many who had a normal hæmoglobin value on their first attendance became anæmic later in their pregnancy Hence the total incidence of anæmia in pregnancy must be greater than 23 8%

TABLE II—INCIDENCE OF DIFFERENT GRADES OF ANÆMIA

Hb (g per 100 ml)	No. of cases
5·0–5 9	9 (2 25%)
6·0–6 9	22 (5 5%)
7·0–7·9	87 (22 0%)
8·0–8 9	219 (55 0%)
9·0–9·9	60 (15·0%)
Total	397

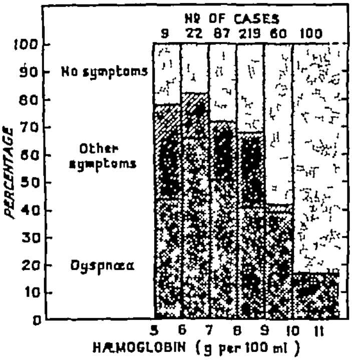

Fig 1—Relation of symptoms to amount of hæmoglobin.

Doyle and McGrath (1954) in a similar survey from the Coombe Hospital, Dublin found an incidence of 31·4% with Hb below 10 g

Dieckmann (1945) found 13% of women at the Chicago Lying in Hospital to have Hb below 10 g

The figure given by Scott and Govan (1949) for Glasgow was 17 6% which they regarded as much higher than those found elsewhere in Britain.

Benstead and Theobald (1952) reported from Bradford that 6 5% of a consecutive series of 2000 women had Hb less than 10 g

Lund (1951) found 20% of 4015 pregnant women attending Charity Hospital, New Orleans, to have Hb below that level.

TABLE III—INCIDENCE OF SYMPTOMS OF ANÆMIA

No of cases	397
No with symptoms	261 (66%)
No without symptoms	136 (34%)
Incidence of symptoms	
Breathlessness	182 (46%)
Tiredness	88 (22%)
Loss of appetite	42 (10%)
Epistaxis	25 (6%)
Headache	17 (4%)
Vomiting	15 (4%)
Sore tongue	6 (1 5%)
Œdema	5 (1%)

The incidence of anæmia seen at the Rotunda Hospital varied according to the season, being lower in the late summer and the autumn (table I) This tendency was also noted by Doyle and McGrath (1954) Similarly Scott and Govan (1940) found that the average monthly hæmoglobin readings in 1946 and 1947 rose in the summer and fell in the winter

From among the 4314 patients investigated, 397 cases of anæmia were studied in detail in the special clinic Table II shows the grades of anæmia found in them The number of cases noted here with hæmoglobin between 9 0 and 9 9 g per 100 ml. is not related to the true prevalence of this grade for many cases in this group were not referred to the special anæmia clinic However, it can be seen that in most of these 397 cases the hæmoglobin lay between 7 g and 9 g As will be shown later, even anæmia of this degree can often be missed clinically

Symptoms

A third of the anæmia patients studied had no symptoms indicating anæmia The order of frequency of

TABLE IV—RELATION OF SYMPTOMS TO HÆMOGLOBIN LEVEL

Hb (g per 100 ml)	No of cases	No symptoms	Dyspnœa	Tiredness	Anorexia	Epistaxis	Headache
9·0–9·9	60	35 (58%)	24 (40%)	11 (18%)	7 (12%)	6 (10%)	2 (3%)

TABLE V—CLINICAL SIGNS OF ANÆMIA IN RELATION TO HB

Hb (g per 100 ml)	No of cases	No signs	With signs
5 0–5 9	9	0	9
6 0–6 9	21	6	15
7 0–9 5	355	169	186
Total	385	175	210

symptoms, when they were present, is shown in table III Only breathlessness seemed to have any relation to the level of the hæmoglobin, being complained of more frequently as the anæmia was more severe (fig 1 and table IV) The other symptoms were not significantly increased as the level of the hæmoglobin fell

As it is generally held that many normal pregnant women complain of breathlessness, the diagnostic significance of dyspnœa is greatly reduced However, of a consecutive series of 100 " normal " pregnant women, at or before six months' pregnancy, with a hæmoglobin level above 10 g there was breathlessness in only 17%, compared with 45% in the anæmic group (fig 1 and table III) As almost all the anæmic women were interviewed before six months' gestation their dyspnœa is unlikely to have had a mechanical origin

Clinical Signs

As is well known, it is quite unsafe to diagnose anæmia on clinical evidence alone This is amply proved in this investigation Nearly half the cases (385) with hæmoglobin below 9 5 g had no clinical signs of anæmia Of 385 cases 210 (54 5%) had clinical evidence of anæmia—i e, obvious pallor of the skin or conjunctivæ, or both The relation of these appearances to the level of hæmoglobin is seen in table V, which shows that, when hæmoglobin is between 7 0 g and 9 5 g, half the cases show signs of anæmia, and that when it is between 6 0 g and 6 9 g three quarters of the cases do so It is only when the hæmoglobin is below 5 9 g that all the patients are clinically anæmic In other words, it is quite impossible to be sure of excluding anæmia clinically when the hæmoglobin is between 6 0 g and 9 5 g, and the great bulk of anæmia in pregnancy lies in this group

TABLE VI—PREDISPOSING FACTORS IN HISTORY

Total 400 cases

Blood loss	
Menorrhagia	97 (*24*%)
Bleeding piles	35 (*9*%)
Epistaxis	25 (*6*%)
Previous anæmia in pregnancy	100 (*25*%)
Pulmonary tuberculosis	11 (*2 5*%)
Diet	
Never ate meat	26 (*6 5*%)
Seldom ate meat	177 (*44 2*%)
Never ate vegetables	11 (*2 5*%)
Seldom ate vegetables	48 (*12*%)

Berry and Cowin (1950) found in school children that the colour of the gums was unreliable as an index of hæmoglobin level

Silverman (1954) observes the colour of the palmar creases in judging the severity of the pallor He notes that when the red colour of the creases is lost, the hæmoglobin may be judged as being below 7 0 g However, this is a severe degree of anæmia, and such a sign cannot be depended on in diagnosing milder grades of anæmia

Hæmoglobinometry is essential in diagnosis as well as in assessing progress It should certainly be routine at the first antenatal visit and again a few weeks before term Abnormal changes were found in the nails of 43 women (11 2%) 14 of these had koilonychia, 12 flat nails, and 17 friable or breaking nails These nail changes were seen mainly in chronic cases At least a third gave a history of having been treated for anæmia previously The [illegible]age parity in this group was 5 7, against the average 3 8 for the total attendance at the Hospital in 1953 The hæmoglobin was often very and averaged 7 g in the 43 cases

Ætiology

The history of each patient included questions possible factors in the production of anæmia Table shows the results, and from these findings it can be concluded that blood loss and intercurrent disease are not primary causes, occurring in not more than a third of the cases (antepartum hæmorrhage was excluded from the series)

The average parity of the total attendance at the Rotunda Hospital during 1953 was 3 8 In 384 severe anæmias the average parity was 4 8 This indicates that parity may be a factor, and in fact the incidence of severe anæmia was found to increase with parity, though not so much as one might expect (fig 2) Doyle and McGrath (1954), dealing with the same population, which there is often a high parity, came to the sa conclusion, but other workers, notably Bethell et (1939), Scott and Govan (1949), and Lund (1951), ha not found this relation

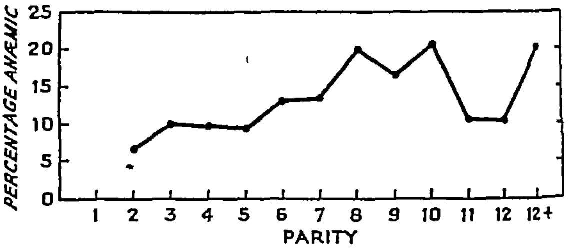

Fig 2—Relation of parity to anæmia.

The only remaining possible factor is inadequa supply of elements essential for formation of hæmoglob As absorption and utilisation are rarely at fault, defective diet is almost certainly responsible From brief questioning of these patients, the most strik finding was the lack of meat in their diet Half of th either never or very seldom ate meat Most of them vegetables besides potatoes indeed only 14% s they seldom or never ate vegetables Protein deficien may be a factor, but there is no doubt that almost these cases respond very well to iron As the main sour of iron are green leafy vegetables, which become sca in late winter and in spring in Dublin, one would exp iron deficiency to increase at this time This is bor out by our figures (see above), and our finding agr with those of Scott and Govan in Glasgow and Do and McGrath (1954) in Dublin This seasonal variati may also be due to the diet containing less vitamin at this time Lund and Kimble (1943) have ascribed similar seasonal incidence to lack of vitamin C T patients were not specifically questioned about oth important iron-containing foods, such as oatmeal a liver

Iron Therapy

At the beginning of the investigation all the wome with anæmia were given a supply of gr 3 ferrous sulphat

TABLE VII—TOLERANCE TO DIFFERENT IRON COMPOUNDS

—	Ferrous sulphate	Molybdenised ferrous sulphate	Ferrous gluconate
Able to tolerate	92 (*46*%)	50 (*55*%)	93 (*84*%)
Unable to tolerate	97 (*48*%)	38 (*41*%)	9 (*8 1*%)
Tolerated with difficulty	18 (*9*%)	3 (*3 3*%)	7 (*6 3*%)
Total	207	91	109

TABLE VIII—COMPARISON OF RESPONSES TO FERROUS SULPHATE AND FERROUS GLUCONATE

(Initial values were at 6 months gestation)

—	No of cases	Initial Hb (g per 100 ml.)	Range of increase in 3 mos (g per 100 ml)	Average increase in 3 mos. (g per 100 ml.)
Ferrous sulphate	13	8·0–8·9	1·6–4·0	2·4
Ferrous gluconate	13	8·0–8·9	1·8–3·9	2·6

tablets † and instructed to take two tablets thrice daily It was soon found that many women complained that they could not continue to take them usually owing to nausea or vomiting These women were then given either 'molybdenised' ferrous sulphate ‡ or ferrous gluconate § in the same dosage (six tablets daily) 91 women were given molybdenised ferrous sulphate, and 100 ferrous gluconate from the start of treatment The rate of tolerance for these three compounds is shown in table VII About half the women could not tolerate ferrous sulphate and 41% could not tolerate molybdenised ferrous sulphate but only 8% were intolerant of ferrous gluconate.

The hæmatological responses to each of these hæmatinics were compared. To eliminate error only cases conforming to the following criteria were selected (1) the hæmoglobin had been estimated monthly from the sixth to the ninth month of gestation (2) six tablets had been taken daily with absence of intolerance and (3) the initial hæmoglobin values had been comparable (8·0–8·9 g per 100 ml) Of the 307 anæmic women 31 fulfilled these criteria 13 had been treated with ferrous sulphate and 13 with ferrous gluconate, and there was little difference in response (table VIII) It has been stated previously that ferrous gluconate gives a better response than does ferrous sulphate (Haler 1952 Lillie et al 1954) but on further analysis little difference is evident Previously reported differences are probably due to differences in toleration The women treated with molybdenised ferrous sulphate are too few for comparison, but the average response of 5 of them under the same criteria, was +2·2 g per 100 ml , which was not significantly more than the response to ferrous sulphate Other workers (Dieckmann et al 1950, Benstead and Theobald 1952) have reported a better response with this preparation

Saccharated oxide of iron || was used intravenously whenever oral iron was not tolerated when there was no response to oral iron or when anæmia was discovered first in the last few weeks of pregnancy Very few cases did not respond to one or other form of iron therapy and these were all found to be cases of megaloblastic anæmia of pregnancy (Moore et al 1955) The usual course of intravenous iron was an initial dose of 50 mg followed by 100 mg daily for the first week and thence forward on alternate days for not more than three weeks In all cases of iron deficiency the response was rapid About 20 cases were treated in this way in the year (5% of the severe anæmias), and the average increase in hæmoglobin was 2·4 g per 100 ml in two or three weeks

Discussion

This common anæmia in pregnancy is attributed to inadequate diet and our findings support this explanation though in a negative way Doyle and McGrath (1954) who studied the same population show conclusively a relation between defective diet and anæmia and it has long been established that a diet poor in protein and iron is the cause of pregnancy anæmia (Strauss and Castle 1932, Bethell et al 1939, Edwards et al. 1953) In fact the incidence of anæmia in pregnancy is a fairly reliable index of the standard of diet of the mothers.

If iron deficiency is slight the hæmoglobin though it decreases may remain above 10 g per 100 ml and be considered 'physiological' Davis and Jennison (1954) point out that even women with initial hæmoglobin levels of 10–13 g benefit from iron therapy We noted that with iron treatment the hæmoglobin rose in many cases to 12–14 g well above the usual levels of the 'physiological anæmia' of pregnancy Benstead and Theobald (1952), Fisher and Biggs (1953) and Davis and Jennison (1954) have all drawn attention to this increase in hæmoglobin to normal (non pregnant) levels in late pregnancy with efficient iron therapy

It has been argued that a mild degree of iron deficiency is of little importance and that in most cases women with it have successful pregnancies without trouble. On the other hand it is obviously desirable that a woman should reach term with her full complement of hæmoglobin and therefore be in a good state to withstand any abnormal blood loss. It seems reasonable and good practice to give an efficient preparation of iron to every pregnant woman during the last trimester to counteract iron deficiency

Summary

On first attendance at the antenatal department, Rotunda Hospital, Dublin, 1 out of every 4 women is anæmic

The incidence of anæmia rises in the winter

Breathlessness is the commonest symptom and appears to be related to the degree of anæmia, but many cases are without symptoms

It is impossible to be sure of recognising anæmia by clinical means unless the hæmoglobin is below 6 g per 100 ml Hæmoglobinometry is essential Spoon shaped or breaking nails indicate long-standing anæmia.

A diet deficient in iron is the most important cause of this anæmia A case is put forward for the routine administration of an efficient iron preparation in every pregnancy

Ferrous gluconate was tolerated well in 90% of cases, whereas ferrous sulphate (whether molybdenised or not) was tolerated in only 50%

In the absence of intolerance, there is little difference in the hæmatological response to ferrous sulphate and ferrous gluconate

We are grateful to the master of the Rotunda Hospital (Dr E W L. Thompson) whose coöperation made the investigation possible and to the director of pathology (Dr H C Moore) for his helpful criticism and his unfailing interest and assistance A grant to one of us (E. W L.) from the Medical Research Council of Ireland is gratefully acknowledged Messrs. Evans Medical Supplies provided the ferrous gluconate

TREATMENT OF MENTAL DISEASE BY SLEEP

O V Kerbikov

DIRECTOR OF THE PSYCHIATRIC CLINIC OF THE 2ND MOSCOW MEDICAL INSTITUTE

In recent years sleep therapy has been studied increasingly both by clinicians and by research workers Complete monographs (Baumann 1953, Angel 1953), and even special issues of journals, have been devoted to the subject But, though its value in certain disorders has been established, many theoretical aspects need further investigation, and much has still to be done to improve the results

Historical

The method has a long history Pierre Janet points out that the treatment of psychoses by prolonged sleep was practised in the early part of last century, when "animal magnetism" was in vogue At the end of that century there was in Sweden a hospital (Janet calls it the Palace of the Sleeping Beauty) where prolonged sleep was the basis of all treatment For mental illness rest in bed was introduced by Korsakov about that time, and came to be widely practised in Russian mental hospitals

Pavlov's work on cortical inhibition and its protective and therapeutic nature supplied the scientific explanation of the method Pavlov showed that inhibition was a protective physiological function developed by the nerve-cell in the course of phylogenesis His work led clinicians to reject deep narcosis in favour of intermittent deep sleep lasting 10–20 hours daily, and to formulate indications for treatment

The main indication for sleep therapy is in patients developing protective inhibition Sleep therapy is less valuable in excited patients than in those showing depressive inhibitory states Treatment based on these principles was introduced in Ivanov-Smolensky's and Protopopov's clinics in 1943–46, and the same principles guide therapeutic practice in Soviet hospitals and clinics today

Nevertheless, the simple formulation of the basic indications leaves many practical problems unsolved, since protective inhibition is seen in a variety of symptoms and syndromes, not all of which respond effectively to sleep therapy Moreover, patients react very differently to any given narcotic Baumann (1953) and others have shown that for patients with an excitable nervous system barbiturates seem most effective, whereas those in whom inhibition predominates respond best to chloral hydrate Hence a wide range of soporific agents is needed

So that we can use smaller doses of drugs, everything is arranged in the sleep-therapy wards to facilitate sleep The action of the drugs is reinforced by monotonous stimuli—e g, the sound of a muffled metronome or the flashing of a blue light—and by heat in the form of hot-water bottles or ozocerite poultices Various methods of conditioned sleep are also employed

Electro-sleep

In our investigations, attention focused first on "electro sleep," developed in 1946 by Gilyarovsky et al The results in 80 patients were discussed by my colleague Korkina (Electro sleep should not be confused with electro-narcosis, which we abandoned because of the serious risk of convulsions, opisthotonos, and subcomatose states) Electro sleep uses a weak electric current, applied as a rhythmic stimulus A direct current is used, with square waves, an impulse duration of 0 2–0 3 milliseconds, and a frequency that can be regulated [illegible] per second The amplitude of the current varies from 5 to 15 mA. Electrodes are usually applied in orbito occipital position

When the current is switched on, a slight pulsa felt deep behind the eyes and a slight pricking in eyelids (I have checked this many times on my After 15 or 30 minutes most patients begin to feel sl and gradually they fall asleep The sleep is often ac panied by dreams, and it may persist after the is switched off Some patients, on the other hand, nev experience more than a feeling of drowsiness

A course of treatment consists in ten to twenty da applications, each lasting 2 hours In severe insom the application is sometimes extended to 4 hours a d With children the length of treatments is reduc to 40 minutes, and the amplitude does not exce 5–6 mA.

Electro sleep produces no clinical evidence of vegetat or somatic disturbance, and is apparently innocuous expe ments on animals have revealed no somatic contra indicatio We deem it prudent, however, not to use electro sleep i patients with severe myopia, glaucoma, or gross cardi insufficiency

An electro encephalogram taken immediately after a trea ment shows a general reduction of cortical electro-activit In some patients normal electrical activity was restored t the cortex after a period of heightened activity This may b a peculiarity of electro sleep, since reduced activity is usu after narcotic sleep Investigations of neurodynamics b Ivanov Smolensky's method (Kirilova) showed that electr therapy often abolishes disturbances in differentiation phasic phenomena disappear, and the tendency for con ditioned motor reactions to become readily exhausted corrected

Results

The best results have been obtained with neuroses an psychogenic reactions displaying asthenia and asthen depression but without severe psychotic featur Permanent benefit was not obtained in obsessional state Presenile psychoses with anxiety or agitated depressio often become worse, and in such states electrotherapy contra-indicated With schizophrenia, there is an improve ment in the early neurotic-like phases, and in the reactiv forms

Among the advantages of electro sleep are the almo complete absence of somatic contra-indications and th possibility of its use in outpatients Drawbacks includ the difficulty of regulating the depth and length of slee the fact that some patients do not sleep during the treat ment, and the impossibility (for technical reason of applying it to disturbed patients, to patients wit delusions of physical influences, and to patients showin negativism

Mechanism

The mechanism of electro sleep has not been full explained Gilyarovsky et al (1952), as well as Serv (1954), who introduced the method in Czechoslovak emphasise the direct effect of the electric impuls on the brain Other investigators deny the pos bility of direct influence on the brain of such current and suggest that the effect is produced by wea rhythmical stimulation of the peripheral receptor Observations at our clinic show that sleep can often b produced by the application of the electrodes to th forearms, without direct application of the current o the brain Yet the fact that presenile patients get wors with this method suggests a central action of the curren since it is difficult to suppose that weak stimulation of the peripheral receptors could have th effect

Alcohol-induced sleep

Since 1949 we have in our clinic induced prolon sleep by intravenous infusion of an alcoholic sol The results in 150 patients were summed up by Ilyinsk

Though alcohol has been used by many workers for the disinhibition, temporarily, of stuporose patients (Ivanov-Smolensky 1952, Gilyarovsky et al 1952) it has not, so far as we know, been used routinely in sleep treatment. The following considerations led us to turn to ethyl alcohol as a sleep-producing medium in the treatment of mental disease, especially schizophrenia.

(1) Well-developed schizophrenia and alcoholism are seldom found together.

(2) Alcohol is an "endogenous" narcotic in that it is a normal product of metabolism.

(3) The combustion of alcohol conserves other calorigenic substances, proteins in particular. It assists in the oxidation of glucose and in its utilisation by the tissues (Meyer 1935 and others).

(4) Alcohol is a component of many blood-replacement fluids and medicines used to combat shock.

After studying the short-term and long-term effects of alcohol in dogs and demonstrating the harmlessness of appropriate doses of the alcoholic mixture on ourselves we proceeded to treat patients with intravenous infusions of the following mixture:

Pure alcohol 96%	60 to 120 g
Sodium chloride	4 g
Calcium chloride	1 g
Glucose	25 g
Distilled water	to 500 ml.

500 ml. of this mixture is given over a period of $1^1/_2$–2 hours. Daily infusions are made, with intervals of 1–2 days after each period of 4–6 days. A course of treatment comprises twelve to fifteen infusions.

Two phases are usually noted in the condition of the patient during each infusion: (1) the phase of disinhibition, which comes on after the administration of 200–350 ml.; and (2) the phase of sleep, which comes on after 250–450 ml. In the first phase there is a combination of euphoria and sleepiness. In the second, the depth of sleep depends on the speed of the infusion. In some patients, and also if the infusion is given rapidly, the first phase is absent. The duration of sleep after each infusion is about 3–5 hours. In patients who formerly abused alcohol sleep may be delayed until as long as 40 minutes after the infusion is completed. Rarely it does not come on at all.

Results

Investigation showed that for 3–5 hours' sleep a blood-alcohol level of 100–170 mg. per 100 ml. was needed, which means that 1·2–1·8 g. alcohol per kg. body-weight must be introduced. During the injection there is flushing of the face and the upper part of the chest, moderate sweating, and diuresis. The blood-pressure falls by 10–20 mm. Hg but returns to its previous level 2–3 hours after the end of the infusion. The patient's appetite is usually increased, refusal of food ceases, and they gain weight; hence we use this method—but with a reduced dose—in weak exhausted patients, and in those who refuse food; and no other method gives such good results.

Among schizophrenics, good remissions were obtained in about half the cases. The best results were in patients with protective inhibition. Good results were obtained in 80% of a group of patients with psychogenic reactive states, mostly of a pronounced psychotic nature, and these patients were enabled to resume their former work. Less satisfactory results were obtained in patients in this group who had an environmentally conditioned hysterical reaction of primitive type. We do not, of course, treat children by this method.

There have been few complications: mild phlebitis has occasionally developed, and some patients have vomited after high doses of the alcohol. In some 2000 infusions we have never had occasion to use cardiac or respiratory stimulants. The commonest technical difficulty is to find suitable veins.

Amylobarbitone and Caffeine

In the past few years my colleague Yagodka has developed a method of using amylobarbitone ('Amytal') and caffeine—drugs which are usually regarded as of value only in the diagnosis of inhibitory states. We have used caffeine (0·2 g. intramuscularly) and soluble amylobarbitone (3–10 ml. of a 5% solution intravenously) routinely, in courses of 10 to 60 daily injections. A few minutes after the short-lived disinhibition and euphoria have passed, many patients doze off during the day and sleep significantly better at night.

This method does not seem to have a very wide scope in schizophrenia; but our results in 70 patients with neuroses, asthenia, and chronic reactive states were good. Obsessional states resistant to all other forms of treatment sometimes yielded to this method. Even temporary relief from painful experiences, by gradually abolishing the pathological conditioned reflexes, seems to hasten recovery.

Nitrous Oxide

Though the euphoric and narcotic properties of nitrous oxide were discovered more than 150 years ago, so far as we know no consistent efforts have been made elsewhere to use 'laughing gas' in psychiatric practice. Our colleagues Zharikov and Matveyev have used it routinely in the treatment of depressive and agitated patients and those suffering from insomnia. As technical difficulties made it impossible to carry out a long course of treatment by inhalation of nitrous oxide, the gas was introduced subcutaneously, where it provided a depot that was later absorbed slowly into the tissues. Experiments on cats showed that 400 ml. of gas injected under the skin was absorbed by the end of 24 hours. Zharikov and Matveyev carried out many similar experiments on themselves.

Each injection is followed by a feeling of lightness and euphoria, and eventually by sleepiness which lasts 4–6 hours. The following night sleep is deeper and longer than usual. When 300–500 ml. of gas is introduced under the skin there is a sensation of bubbles running in different directions, but crepitation disappears completely within 24 hours.

32 cases of mild reactive depression, involutional depression, and cyclothymia were treated, each receiving some 400–500 ml. of gas at each of 12 injections. It is too early to assess the results, but it is clear that sleep is improved. The patients often sleep for 2–3 hours after the injection, and many need less sedation at night. Most are improved in mood and experience a sense of well-being. Whether these effects are lasting cannot yet be stated.

INTRA-ARTERIAL TRANSFUSION BY THE FEMORAL ROUTE

RICHARD NEVE *
M B Lond , F R C S
LATE SENIOR SURGICAL REGISTRAR, SOUTHMEAD HOSPITAL, BRISTOL LATE REGISTRAR, PROFESSORIAL SURGICAL UNIT, UNIVERSITY OF BRISTOL

As a means of combating arterial hypotension, intra-arterial blood-transfusion has been used for more than ten years This method is needed but occasionally in cases of extreme emergency, and the femoral route offers many advantages, both in the ease of giving the transfusion and in the freedom from risk

An apparatus simple to maintain and easy to use is essential That described here fulfils most of the criteria of simplicity and safety It can be constructed from standard blood transfusion equipment with a few additions, and a stand for it is within the capabilities of most hospital workshops for the cost of a few pounds

THE APPARATUS (fig 1)

Positive pressure is provided by an aneroid sphygmomanometer Between the inflated arm band (which acts as an air reservoir to maintain constant rather than intermittent pressure) and the pressure gauge is inserted a T piece which is connected to the air intake on the bottle The bottle is held in a quick release clamp in the stand so that no screw top need be used to prevent leakage The efferent tubing is led through a Macintosh valve, and a spring clip on a 1 in. length of rubber tubing is used to control its sidepiece The tubing then passes to a ' Record ' fitting, such as is used on standard blood giving sets for connection to the needle A Greenfield's lumbar puncture needle has been found to be the most satisfactory The stilette is modified so as to project for $^1/_2$ cm beyond the end of the needle point and is rounded (fig 2) Two artery clips are convenient for controlling the flow whilst filling—one above and one below the valve

A two way apparatus (fig 3) has also been designed. This simplifies the giving of more than one bottle at a session by changing the positions of the clips The second bottle can be given while the first is changed, and so forth

Preparation for Use

The transfusion tubing, carrying valve and needle, are sterilised and kept in a drum. When the apparatus is the proximal end of the tubing carrying the filter is in into the bottle This slides into the screw clamp Precaut must be taken to ensure that the ground glass plunger in Macintosh valve is freely movable before blood is to fill it Air is excluded in the normal way and the dis end of the transfusion tubing is plugged into the sidep of the Greenfield's needle The main channel of the need houses the stilette which must be withdrawn before punc the vessel, and it is not until the needle is well within the artery that the position of the tap is changed so as to perm blood to enter the needle from the tubing

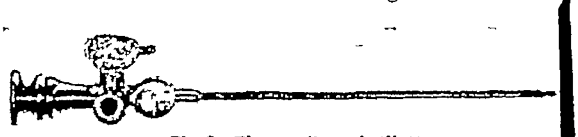

Fig 2—The needle and stilette.

TECHNIQUE OF ARTERY PUNCTURE

The femoral artery can usually be punctured percutaneous and it may be made more prominent by external rotati and extension of the leg over a sandbag under the buttock The needle should enter immediately below the inguin ligament in an upward direction, since the femoral vess rapidly recede beneath the adductors as they leave the femo triangle and become *relatively less accessible* If any difficult is experienced in locating the artery or puncturing it, there should be no hesitation in cutting down and exposing through a vertical incision downwards from the inguinal ligament at its mid point

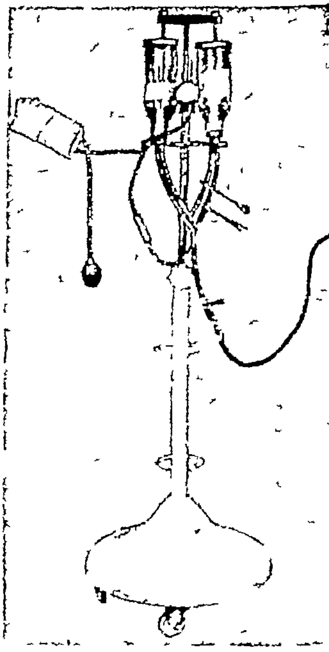

Fig 3—The double apparatus.

The Greenfield's needle has been adopted since it has a wide enough bore to provide for rapid transfusion and is long enough to allow the operator to steady it easily whilst leaving $1^1/_2$–2 in within the lumen of the artery It has a short bevel and is unlikely to damage the opposite wall of the vessel as it enters The stilette is removed and as the needle point enters the artery, arterial blood will spurt back. The stilette is immediately reinserted and with its round end projecting, the needle is advanced towards the umbilicus for 1 to 2 in It is now firmly gripped by the vessel and need *not* be *held* When it has been advanced to the desired point, the stilette is withdrawn the tap turned through 90°, cutting off the open end of the needle and connecting it to the transfusion tubing

The screw clamp on the stand absolutely prevents an leakage around the bung It has not been found nec to use locking connections on the rubber tubing or to them, since if rubber and glass connections are chosen fully they withstand pressure well up to the range required and when the rubber perishes and starts to stretch it shou be renewed

A Macintosh valve renders air embolism almost impossib but a manually operated source of positive pressure has selected since the need to maintain the pressure by hand w necessitate the constant presence of the operator

ADVANTAGES OF THE METHOD

The femoral artery is the best site for intra arter transfusion for two reasons First, the vessel is

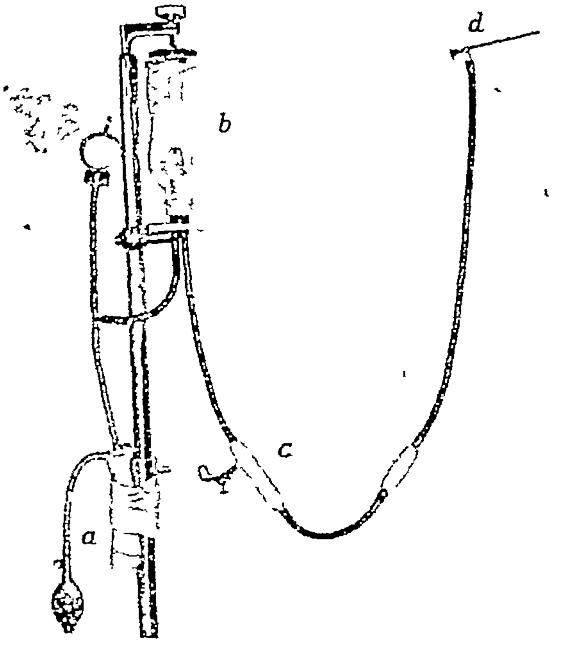

Fig 1—The single apparatus: (a) aneroid sphygmomanometer (b) bottle in quick release clamp , (c) Macintosh valve , (d) Greenfield's needle

---

* Now at Kimberley, British Columbia Canada

nctured percutaneously in many cases and even if
tting down is involved, this is a simpler and quicker ethod than cannulating a radial artery which may be severe spasm (Porter et al 1948) and less shocking than tering the position of the patient to allow transfusion the lumbar route (Haxton 1953)

Secondly, the method is freer from complications— any rate than the radial route

Gangrene of finger tips, and in one case of the thumb s been reported after using the radial artery In two cases orter et al. 1948 Seeley 1949) the use of dextran or plasma s been incriminated as the cause and the gangrene appears have been the result of perfusing a peripheral artery with noxygenated fluid. One would expect there to be less danger this when a large vessel such as the femoral is used and hen there is adequate opportunity for the transfused fluid mingle with oxygenated blood before being carried to the tremity of the limb

In a further case (Bingham 1932) gangrene of the digit llowed the use of blood presumably owing to an anatomical nomaly—a further risk to radial-artery ligation

Thrombosis of the femoral artery following intra arterial ansfusion has occurred in one case (Liaras et al 1949) n this, the thrombosis was at the site of needle puncture l cm below the inguinal ligament) in a patient of 72 after 50 ml of plasma had been given The proximal site of thrombosis seems to exclude the plasma as the cause and the mb recovered after embolectomy A massive extravasation f blood was found at the site of thrombosis which points ither to leakage around a needle which was only just in the rtery or to damage to an atheromatous plaque The former isk can be obviated by the technique I have described he latter is intrinsic in the use of artery puncture in n atheromatous vessel. It has seldom occurred following he wide use of the femoral artery for arteriography

Vascular spasm often follows puncture of the femoral rtery but it can be expected to resolve spontaneously Relief of spasm can be rapidly obtained by the direct pplication of papaverine (Kinmonth 1952) if the vessel as been exposed

I am indebted to Prof R. Milnes Walker Mr W M Capper Mr J A. Pocock, on whose patients intra-arterial trans ons have been performed to Mr R. E Horton for help l encouragement in the preparation of this paper; to A. E Christmas F.I.B.S.T., who helped to design the ck release clamp and built the single headed apparatus l to the group engineer's department at Southmead spital who built the double apparatus.

DOES REDUCED BLOOD-SUPPLY CAUSE PAIN?

MICHAEL KELLY
M.D Adelaide

STANHILL MEDICAL CENTRE, MELBOURNE AUSTRALIA

DURING the past twenty years ischæmia has become a andard explanation for pain of unknown origin

Stitch is said to be due to ischæmia of the diaphragm apps 1941) trigeminal neuralgia to paroxysmal ischæmia deep facial structures (Karl et al 1945); headaches to lative ischæmia of cranial muscles (Tunis and Wolff 1954) on articular rheumatism (Ray 1934) decompression pain ahlstrom et al. 1930) proctalgia fugax (Ryle 1942) smenorrhœa (Woodbury et al 1947) and many other pains ve been attributed to ischæmia.

But apart from coronary insufficiency, intermittent laudication arterial embolism and arterial spasm w pains are certainly attributable to reduced blood upply In most cases we have no evidence of ischæmia nd are guided chiefly by analogy—especially by the classical experiments on constriction pain in working muscle (MacWilliam and Webster 1923 Lewis 1932, 1942)

The fist is repeatedly clenched while the circulation of the arm is arrested with a manometer cuff There is no pain if the muscles are not worked but the forearm muscles become painful and tender after 20 contractions—intolerably so after 40 When the cuff is released the pain vanishes in 3 seconds

Factor P is not Produced by Anoxia

Lewis believed that a chemical substance (factor P) was produced by working muscles without oxygen and diffused out to the pain nerves in the tissue spaces But the forearm is not ischæmic it is congested with venous blood Moreover, there is ample proof that the pain is not due to lack of oxygen

(1) The pain comes after 20 contractions whether the forearm is congested by a manometer cuff or exsanguinated by an Esmarch bandage (my observations)

(2) The pain comes after 35 contractions when the manometer pressure is at 50 mm Hg—the circulation is not occluded (my observations)

(3) The pain appears after 60–100 contractions in a forearm exsanguinated by digital pressure on the brachial artery alone—not on muscles or nerves (Kelly 1955)

(4) Anoxia which causes dyspnœa and cyanosis does not accelerate the onset of pain (Harpuder and Stein 1943)

(5) The onset of pain is not accelerated by vasoconstriction or delayed by vasodilatation (Rein and Schneider 1937 Lewis et al 1931 Harpuder and Stein 1943)

(6) Resting muscles, and even non muscular tissues, generate pain when the constricted limb is put in hot water for 5 minutes (Harpuder and Stein 1943) After a shorter heat stimulus 8 to 12 contractions will generate pain

Factor P is not a Circulating Biochemical Substance

Though factor P does not appear during 30 minutes circulatory arrest it remains stable (said Lewis) once it appears Yet the pain vanishes as soon as the circulation is restored Factor P is not a known metabolic product the pain is not influenced by changes in the pH (Matson and Forster 1936) or by lactic acid or histamine (Harpuder and Stein 1943) Factor P cannot be detected in the circulating blood Harpuder and Stein generated ischæmic pain in both legs and tried to flood the system by releasing both femoral cuffs at once Then the usual 20 contractions were required to generate pain in the forearm

Can a stable chemical product become unstable when the blood flows? This would require its destruction by an anti factor which had disappeared from the forearm yet is normally in excess in the blood. Such a potent substance would surely have been discovered ere this. The only other possibility (if factor P is a chemical substance) is that it is washed away—i e it must be diffusible The chlorides of sodium and potassium are diffusible and we know something about muscle pains which they cause

(1) 1% potassium chloride solution injected into the nutrient artery to a muscle causes severe pain for 45 minutes (Harpuder and Stein 1943)

(2) Hypertonic saline solution injected intramuscularly causes pain for more than 30 seconds (Lewis 1942)

Therefore the pain from an undetectable circulating substance would not be likely to disappear in 3 seconds

Factor P and Muscular Fatigue

Whenever I have made the experiment I have noticed a feeling of fatigue and muscular weakness increasing to paralysis The increasing tightness of the cuff gradually merged with the fatigue into intolerable pain I was once dissecting in tight rubber gloves when the fingers became weak and almost paralysed fatigue appeared in the forearms and progressed until it was exactly like ischæmic pain

The muscles take 20 minutes to recover If they are worked again in 10 minutes the pain comes after 12 contractions, and if they are fatigued from normal work, less than 20 contractions are required (Lewis 1942) Fatigue can do what neither vasoconstriction nor anoxia can do—intensify ischæmic pain Fatigue is not only an inability to contract, it is also a muscular sensation which intensifies to pain and tenderness

Partial Nerve block

When the vessels are occluded, cutaneous sensory disturbances are produced by pressure on nerves (Lewis et al 1931, Barlow and Pochin 1948, Sinclair 1948, Merrington and Nathan 1949, Addis et al 1950) The forearm goes numb when the cuff has been inflated for 10 minutes, and for shorter periods after nerve injuries (Gilliatt and Wilson 1953, Marshall et al 1954) Perhaps the pain and tenderness are also neural, it is well known that muscles recovering from nerve injury are liable to fatigue and painful cramps

When I partially blocked my ulnar nerve with procaine at the medial epicondyle, I felt aching pain in the hand and the ulnar side of the forearm after 30 clenchings of the fist When my lateral popliteal nerve was compressed, and the ankle was rapidly flexed and extended, pain and tenderness developed in the anterior muscles but not in the calf (Kelly 1955) If the pressure was released while the movement went on, the pain vanished

While the limb is constricted, there is an intensified electric discharge from the compressed nerve and its peripheral field (Kugelberg 1946) Muscular coördination is poor, and deep reflexes are absent (Gellhorn and Thompson 1944), muscles become weaker after 20 minutes even if they are not worked (Marshall et al 1954) Painless lesions of skin (blister) and muscle (saline solution injected) become painful and generate more impulses (Nathan 1953) When he compressed the nerve alone Nathan generated muscular and cutaneous pain as before, though the circulation was free

Heat, Hyperalgesia, and Factor P

The constricted limb becomes generally hypersensitive, skin hyperalgesic (Sinclair 1948), and deep wounds painful (Addis et al 1950) Heat not only intensifies factor P in muscles, but also causes burning pain in a constricted finger (Harpuder and Stein 1943) Lewis (1942) showed that heat intensified erythralgic cutaneous hyperalgesia to burning pain, the constricted finger and the ischæmic muscle are therefore hyperalgesic

An artificial lesion in muscle becomes spontaneously painful (by summation) when its nerve is compressed (Nathan 1953) If a fatigued muscle is substituted for a tender spot, again the threshold is lowered by compression of the nerve Muscular fatigue is therefore a hyperalgesic state which is intensified to pain by partial nerve-block

Ischæmia is not a Common Cause of Pain

The causation of pain is usually multiple (Wikler 1953) Several subthreshold factors combine to give threshold stimulation Often the cause which seems most likely is merely one of the effects of a deeper common cause Cardiac pain is often due to reduced coronary circulation, but additional factors are required to precipitate the pain, which is absent for long periods in every case Pain from arterial embolism (Lewis 1936) and intermittent claudication (Boyd et al 1949) usually depends on factors additional to loss of blood-supply In Raynaud's phenomenon lesions of nerves are partially responsible (Marshall et al 1954) Causalgia after nerve injuries is not more common when the main artery has been severed (Sunderland and Kelly 1948)

When we say that a common but obscure pain (the stitch) is due to ischæmia of muscle, we are guided by [illegible] and not by observation Deep and widespread [illegible] re often associated with tenderness of muscles Sometimes a primary muscular lesion is res for radiating pain and tenderness (Kellgren 1 Sometimes, on the other hand, the muscular pain tenderness are reflex—secondary to visceral or deep lesions (Sinclair et al 1948) Because we that ischæmia causes pain and tenderness in muscles we assume that it causes many other If, however, the pain is not ischæmic but neural, we shall have to discard ischæmia as a common of pain

Summary

Ischæmic muscles can be exercised without pain considerable periods if their nerve supply is und

Pain develops in muscles which are worked with blood-supply but with nerves partially blocked

So-called ischæmic pain in muscles is due chiefly fatigue through partial nerve block

Factor P cannot be detected in the circulating blood

There is no evidence that ischæmia is a general of obscure pains

A CASE OF FAVISM

O R McCarthy
B A, M B Dubl

LATE SENIOR HOUSE PHYSICIAN, ST RICHARD'S H
CHICHESTER

FAVISM is a disease in which acute hæmolysis foll the ingestion of broad beans (*Vicia fava*) or inhala of their pollen It is seen chiefly in Sardinia, but also Sicily, Italy, Greece, and North Africa (Luisada 1 Sporadic cases have been reported from France Spain, 10 have been described in the United (Larkin 1953), and 2 in Britain (Diggle 1953) All th affected were people of Mediterranean ancestry

Symptoms appear 5–24 hours after ingestion of beans, or in a matter of seconds after inhalation of t pollen There is malaise, nausea, and vomiting Pyrex if present, is irregular The patient becomes jaund and his liver and spleen may enlarge There is a in the red-cell count, a rise in serum bilirubin serum-potassium, a reticulocytosis, and often a cytosis The urinary urobilin may increase, and al uria and hæmoglobinuria may be present An m d-cell fragility may be found in the early stages, but ually fragility is normal

The severity varies from the acute case requiring ood transfusion to mild ambulatory cases with few ms. The disease is commonest in male children during e pollen season (May to August) Skin testing with an tract of the bean or pollen gives variable results Each tack is followed by a period of about 6 weeks' immunity om the disease during which time skin tests are gative

The condition is usually regarded as a manifestation allergy, though this is not accepted by all authorities *Journal of Pediatrics* 1954)

Case-record

A 9 year old boy was admitted to hospital on July 2 1954 investigation of recurrent attacks of jaundice

His present illness had begun on June 26 1954 At supper that day he ate some cooked home-grown broad beans d during the evening he felt rather unwell. Next morning ate some more beans, and about 2 hours later he had a ivering attack and felt ill He went to bed early and the llowing morning (June 28) he was found to be jaundiced. o vomited several times during that day and night and en slowly improved By July 1 the jaundice had begun fade

Previous history—He had had jaundice twice before in 952 and in 1953 each time during the late spring Both ttacks were closely preceded by a meal containing broad eans, and each attack consisted in shivering malaise omiting and jaundice Neither had been as severe as e *1954* attack, and on neither occasion was a doctor lled

Family history—His mother volunteered the information at her maternal uncle used to become ill and jaundiced very time he ate broad beans. He was *unmarried* and died ine years ago So far as she knew no-one else in the mily had had recurrent jaundice The patient was born England and had lived all his life in England His parents randparents, and the grand uncle's parents had all been born the British Isles.

On examination he was slightly above average height and eight for his age The scleræ were yellow and the skin ightly so The liver edge was palpable just below the ostal margin, and was tender The *spleen* was not palpable and no other abnormality was found on physical amination.

Blood examination on July 5 showed Hb 74% red cells 400 000 per c.mm reticulocytes 24% and serum bilirubin mg per 100 ml Examination on July 7 showed reticulocytes 10% normal red-cell fragility (hæmolysis starting at 44% and complete at 0 28%) white cells 8700 (polymorphs 0%, lymphocytes 42% monocytes 6% eosinophils 2%) ed cells normal in shape and size and no punctate basophilia. he anti-globulin reaction was negative By July 16 the eticulocytes had dropped to 1 5% Wassermann and Kahn eactions were negative

Other examinations—There was no bilirubin or urobilin in he urine An intradermal skin test on July 15 using an xtract of broad beans was negative

Progress—There was an evening rise of temperature up o 99·6°F for a few days The jaundice cleared within 4 hours of admission There were no further symptoms nd signs, and he was therefore discharged on July 18 having een warned never to eat broad beans again

On Sept 9 he was seen as an outpatient He had remained t in the interval. A further skin test was negative Blood xamination showed Hb 100%, reticulocytes less than 0·2% rum bilirubin 0·8 mg per 100 ml., normal red cells and latelets, and no evidence of spherocytosis.

Discussion

The diagnosis was made (1) on the history of symptoms ppearing within 24 hours of eating broad beans; (2) on he evidence of hæmolysis as shown by the low hæmo lobin the low red-cell count and the high reticulocyte ount; and (3) on the absence of excessive fragility or bnormal shape of the red cells The negative antiglobulin reaction on July 7 was to be expected since the hæmolytic episode was over by that time

This is probably the first case of favism to be described in a person of non Mediterranean descent The diagnosis might not have been made but for the mother's insistence on the connection between the beans and the jaundice (she probably recalled that her uncle had shown a similar susceptibility)

Diggle (1953) has pointed out that where hæmolytic anæmia is found in a person of Mediterranean ancestry, the possibility of favism should be borne in mind. Dacie (1954) noted that in many of the published case-reports on favism, the original diagnosis had been of "acute hæmolytic anæmia—? Lederer's type" the correct diagnosis was made after eliciting a history of recent ingestion of beans

This case suggests that favism should be considered as a cause of hæmolytic anæmia not merely in Mediterranean people or their descendants but also in persons of British stock

Summary

A case of favism is described in an English boy of 9 *This is* the first report of the condition in a patient of British descent There are grounds for believing that the boy's grand uncle had the same disease.

Favism should be considered as a possible cause of hæmolytic anæmia and unexplained jaundice, even in patients who are not of Mediterranean stock.

I am indebted to Dr G A. Emmerson under whom the case was admitted, for permission to publish this report and to Dr G A. Harrison and Dr Colin Knowles, who were responsible for the pathological investigations.

PEPTIC ULCER IN A HÆMOPHILIAC TREATED BY GASTRECTOMY

WILLIAM WALKER
M.D Durh.
LECTURER IN CHILD HEALTH UNIVERSITY OF DURHAM

THE danger of bleeding after injury in hæmophilia has long been known and Birch (1937) reported many deaths following even minor surgery

Craddock et al (1948), reviewing the problem of surgery in hæmophilia drew attention to the greater risks of bleeding in cases where local hæmostatic measures could not be applied an arm was successfully amputated in a hæmophiliac but in abdominal surgery the danger of hæmorrhage was so great that many authorities regarded the risks attending infection in acute appendicitis as less serious than those attending operation Craddock et al also described their own *case of acute appendicitis* treated by operation in which the clotting time was kept within normal limits by the use of fresh blood plasma and antihæmophilic globulin and yet the patient died At necropsy blood was found in the peritoneum and pleura and a large hæmatoma not communicating with the peritoneum was found at the site of the incision They calculated that the mortality rate associated with abdominal surgery in probable hæmophilia was at least 27% but where only proved cases of hæmophilia were considered the mortality rate was 60%

I describe here a case of repeated hæmatemeses due to peptic ulcer in a hæmophiliac who subsequently underwent gastrectomy Although the operation was successful I am convinced that surgery in hæmophilia must be avoided if at all possible

Case-report

The patient, who was in his early forties, came from a family of bleeders The family history is typical and illustrates the transmission of hæmophilia by unaffected females to their male children (fig 1) Both the maternal grandfather and a great uncle were said to have died from bleeding, but the exact circumstances are unknown

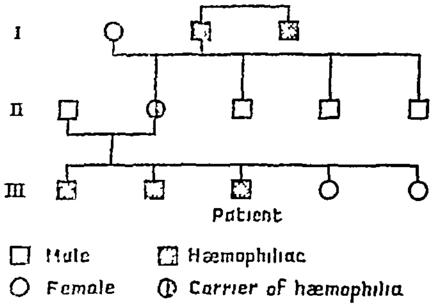

Fig 1—Patient's family tree

History of Bleeding —Although never a florid hæmophiliac the patient has had recurrent epistaxes, skin hæmorrhages, and, at the age of 21, a hæmarthrosis of his left knee Superficial wounds on many occasions bled unduly but never gave rise to anxiety, in fact, severe lacerations did not require any special treatment to produce hæmostasis The bleeding time was repeatedly normal, whereas the clotting time was often prolonged In September, 1952, his clotting time (Lee and White) was 9 minutes (normal 5–10 minutes), bleeding time 2 minutes, clot retraction normal, prothrombin and fibrinogen 93% and 0 2 g per 100 ml respectively, and prothrombin consumption 30% In view of the normal clotting-time specimens of his blood were sent to Dr R G Macfarlane and Dr Rosemary Biggs at the Radcliffe Infirmary, Oxford They confirmed the diagnosis of hæmophilia "Our tests show that he has a definite deficiency of antihæmophilic globulin, in other words he has classical hæmophilia The results cannot at present be expressed quantitatively"

History of Dyspepsia —For 20 years the patient had symptoms typical of duodenal ulcer, which had been repeatedly demonstrated by barium meal 7 years ago he had a perforated duodenal ulcer, which was sutured, fresh blood being given before operation In the seven years from the perforation to the present illness he had eleven hæmatemeses, seven were serious and necessitated admission to hospital and nearly always blood transfusions The amount of blood given varied at first as little as 3 pints was required, but on each of the two most recent admissions—i e, August and October, 1952—more than 20 pints was needed Fresh blood from emergency donors was used whenever possible It was not uncommon for the patient's Hb level to be as low as 4 5 per 100 ml after hæmatemesis The duration of his stays in hospital varied from 10 to 40 days Continuous medical treatment, including prolonged periods of rest, did not produce appreciable improvement, in fact, the hæmatemeses became not only more frequent but also more severe The patient was virtually unemployed, and his family life was becoming disrupted Moreover, Prof F J Nattrass felt that sooner or later the patient would die from a hæmatemesis, and that therefore the considerable risk of gastrectomy was justified

Admission for Gastrectomy —Preparations to control bleeding during and after gastrectomy were made on the assumptions that (1) the clotting defect in hæmophilia is due to the lack of antihæmophilic globulin, (2) provided antihæmophilic globulin can be maintained at an adequate level, the clotting and other hæmostatic mechanisms are normal (3) antihæmophilic globulin is present in freshly collected blood, but after storage its concentration tends to fall (although this is a variable factor), purified antihæmophilic globulin is not available in large quantities and that present as a contaminant of purified fibrinogen has been inconstant and disappointing in controlling bleeding in hæmophilia, (4) antihæmophilic globulin is only effective for 24–48 hours after injection, and is probably much less this (R G Macfarlane personal communication), and (5) relatively large amounts of human blood are necessary to provide enough anti philic globulin to overcome the clotting defect in h (Dacie 1952), and small amounts of blood or plasma recommended by Schiller et al (1948) are unreliable It realised that repeated transfusions of plasma might lose effect as the result of the patient's becoming immunised antihæmophilic globulin, but this risk was unavoidable accepted, as were those of plasma hepatitis, &c

Preoperative Preparation —Twenty emergency blood-do were tested to make sure that their blood was compatible the patient and with each other, and that their plasma promote normal clotting of his blood On the day b operation blood from twelve such donors was colle into acid citrate dextrose solution and within three h transfused into the patient by exchange transfusion. T technique was simple, siliconed giving and taking sets b used to withdraw blood from one arm while the fresh bl was run into the other There were no technical difficult and the rate of bleeding was controlled by altering the tens of the tourniquet, and the rate of infusion by positive press An exchange of 10 pints was completed in 80 minutes, which the remaining 2 pints was run in by slow drip this procedure normal blood was substituted for at least of the patient's blood Perhaps a similar quantitative r might have been achieved by transfusing about five p of fresh plasma However, the exchange transfusion did upset the patient, and since it was completed within an h and a half, he obtained a good night's rest before operation.

Partial gastrectomy was done by Prof Norman Hodg on Jan 26, 1953, at 9 30 A.M, 20 hours after the exch transfusion was completed It would probably have b wiser to operate immediately after the transfusion Dur the operation 1 pint of blood, collected on the previous d from a selected donor, was given There were many m adhesions between the liver and the whole of the curvature than are usually seen after a perforation W these were separated, the stomach was seen to be di The duodenum showed stenosis due to a chronic ulcer in *first part, and was slightly adherent to the pancreas* easily separated The duodenum was divided and cl without difficulty On exposure of the lesser greyish swelling of unknown nature was found and with considerable difficulty, together with the sto An anastomosis was made by bringing the jejunum throu the transverse mesocolon A Penrose drain was *down to the stump of the duodenum, and the a* wall was sutured in layers During the operation the b was no more severe than usual, and the blood appe to coagulate in normal time

Postoperative Course —During that afternoon 1 pint blood, collected on the previous day, was given and fo by 1 pint of saline solution At 6 15 P M the patient v bloodstained material, and thereafter small amounts of bl stained fluid were aspirated from the "stomach"—about every 15 minutes, 33 oz being withdrawn by midni Thereafter the bleeding seemed to increase, because times 4 oz was aspirated in 15 minutes So a tra[illegible] bank blood was started, 2 pints being given over the 6 hours, after which saline solution was substituted for bl (fig 2)

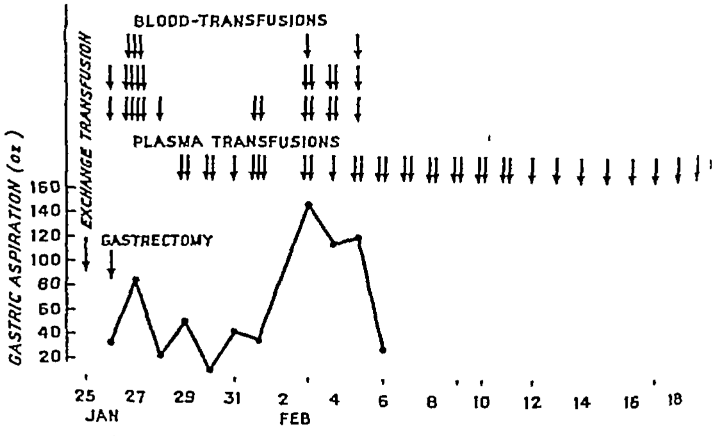

Fig 2—Postoperative course Each arrow represents 1 pint.

Next day 37 oz. of deeply bloodstained material had been aspirated from the stomach since midnight and the patient was in a state of profound circulatory collapse semiconscious, and very apathetic, with pulse-rate 140 and systolic blood pressure 90 mm. Hg A transfusion of bank blood was again started 1 pint being given in 10 minutes and 2 more in the next hour followed by 750 mg of fibrinogen (M.R C Blood Products Unit) which contains antihæmophilic globulin, and by 2 pints of blood freshly collected from specially selected donors The patient improved and was conscious, but with blood pressure 110/70 mm. Hg and pulse-rate 120 Later that day 4 pints of fresh blood was given and a rectal drip of tap-water was started because the patient was becoming dehydrated The stomach was aspirated hourly deeply bloodstained material being obtained on every occasion until 8 and 9 P.M During this day the patient had 84 oz. withdrawn and received 5 pints of bank blood and 6 pints from emergency donors in fact his entire blood volume was replaced. In addition he was given 750 mg of fibrinogen which in antihæmophilic content is said to equal 500 ml of plasma, but in fact is probably equal to only 50 ml of plasma (R G Macfarlane personal communication)

From Jan. 28 to Feb 1 the patient was much better rational, and reasonably coöperative but still very anxious He was given 1 pint of fresh plasma morning and evening—i.e about every 12 hours. The plasma used was of the same ABO and Rh groups as the patient s but not cross matched Freshly collected blood from two donors was centrifuged and the plasma siphoned off and pooled A new drip using a small needle was set up on each occasion the transfusion taking about 20 minutes. During these five days the patient s condition remained satisfactory although about 30 oz of bloodstained fluid was aspirated daily Throughout this time 2 oz of either water or orange-juice was offered each hour On the day of operation the patient took only 2 oz. but next day he took 20 oz and thenceforth he gradually increased his intake to about 60 oz a day

On Feb 1, in addition to the fresh plasma he was given 2 pints of day-old blood to counteract mild anæmia. He seemed well the operation wound was healing normally and there was no bleeding The transfusions were therefore discontinued

Next day his condition was satisfactory and no bleeding occurred but on Feb 3 at 7 15 A.M , 34 hours after the last plasma transfusion, he vomited 18 oz of blood, and 18 oz. more was aspirated in the next 15 minutes so 1 pint of plasma (18 hours old) was given at 9 30 A.M and 1 pint newly collected from emergency donors at 10 A.M In spite of this 20 oz of bloody fluid was being aspirated every half hour the blood pressure was falling and the pulse rate was 120 A transfusion of fresh blood from emergency donors was started at 12.30 P.M 5 pints being given, and 145 oz. of fluid being aspirated from the stomach, during the day

On Feb 4 1 pint of fresh plasma and 4 pints of fresh blood were given and 114 oz aspirated. On Feb 5 1 pint of fresh plasma was given in the morning 3 pints of fresh blood during the day and 1 pint of fresh plasma in the evening ; and 121 oz. was aspirated On Feb 6 the patient s general condition and mental outlook had much improved 1 pint of fresh plasma was given in the morning and at 10 A.M 30 oz. of fluid was withdrawn after which no further aspiration was required Another pint of fresh plasma was given in the evening

From Feb 7 to Feb 11 1 pint of fresh plasma was given each morning and evening On Feb 11 the wound was healing normally and the last of the sutures were removed From Feb 12 to Feb 22 one pint of fresh plasma was given each evening By Feb 12 the patient s weight normally 11 st 4 lb had decreased to 10 st but on this date he started to take food by mouth once more On the six consecutive days up to Feb 22 tests for occult blood were negative. The plasma transfusions were stopped after Feb 22 and there was no further bleeding The patient progressed well and was discharged home on Feb 27 a month after admission during which time he had received 39 pints of blood and 38 pints of fresh plasma. This represents more than 100 donations of blood and but for the donors it is unlikely that he would have survived

Follow up—The patient was seen at monthly intervals for 6 months and apart from a feeling of fullness and some vomiting after meals remained well. His stools were tested for occult blood during the first three months convalescence but were negative on each occasion His appetite was satisfactory he was gaining weight and no anæmia developed Seen in October 1954, 21 months after gastrectomy, he said he felt perfectly well and was doing heavy manual work without difficulty He weighed 11 st 4 lb (his normal weight) and had no complaints.

Discussion

It is difficult to overestimate the risk attending surgery in hæmophilia Even if the clotting time is nearly normal or can be maintained within normal limits by injections of fresh plasma or of antihæmophilic globulin, severe bleeding may still occur (Merskey 1951, Baserga and de Nicola 1951)

Until potent antihæmophilic globulin is available in large amounts fresh plasma is the best means of supportive treatment in the case of accidental injury or if operation cannot be avoided Very large amounts of fresh plasma are required and should be given frequently—e.g every 12 hours—because the active principle survives only a few hours and therefore may fall to dangerously low levels between transfusions Transfusion therapy should be continued as long as there is evidence of bleeding and until it is reasonably certain that healing is well established It is important that during the operation the circulating blood should contain adequate amounts of antihæmophilic-globulin because otherwise arterial hæmorrhage is very likely to recur

Macfarlane et al (1954) have reported the value of bovine and antihæmophilic globulin in patients undergoing surgical treatment, and it seems that this is the real hope for these unfortunate people. At present it is not available in large amounts, and in some cases it seems to carry the risk of producing thrombocytopenia, although in none of these workers cases did this cause bleeding

Any method by which antihæmophilic globulin is introduced into a patient to whom it is a 'foreign protein" carries the risk that the patient may become immunised to it and therefore no longer derive benefit from it.

Summary

A case of repeated hæmatemeses due to duodenal ulcer in a hæmophiliac is reported

Eventually gastrectomy was done The régime before and after operation is described.

The need to avoid major surgery in hæmophilia at practically any cost is emphasised

I am indebted to Professor Nattrass and Professor Hodgson for permission to publish Dr R G Macfarlane and Dr Rosemary Biggs for confirming the diagnosis of hæmophilia the Regional Transfusion Centre for their service ; and the doctors and nurses of the Royal Victoria Infirmary for their skill and care in looking after the patient

'There is one possible consequence of the use or the testing of thermo-nuclear weapons which is seldom mentioned but which must be in the minds of some biologists It has to do with the effects of radiations upon symbiotic and parasitic organisms Now living things live together in relationships which have themselves become adjusted over long periods of selection. Many trypanosomes, for instance do little harm to the hosts in which they live A mutation in a population of trypanosomes resulting in the production of a new viable form can have very serious consequences for the host population which may be faced with a new situation with which it is not fitted to cope —Prof PAUL G ESPINASSE *Manchester Guardian* March 31 1955

Reviews of Books

British Practice in Radiotherapy

General Editors SIR ERNEST ROCK CARLING, LL D, F.R C S, F.R C P, F F.R, consulting surgeon, Westminster Hospital, B W WINDEYER, M B, D SC, F R C S, F R.A C S, F F R, professor of radiology, University of London, D W SMITHERS, M D, F.R C P, F F R, professor of radiotherapy, University of London London Butterworth 1955 Pp 516 £4 5*s*

SIXTY-FIVE authorities have contributed to this picture of radiotherapy practice in Great Britain today The volume, though complete in itself, is also a companion to *British Surgical Practice*

Part I deals with general problems, including the basic physical aspects, biological problems and effects, and methods of application Part II is concerned with treatment Systematically each chapter deals with a subject for which radiotherapy is used, and its use is discussed fully and clearly by a physician or surgeon and a radiotherapist The necessary and growing coöperation between radiotherapy and other departments is stressed throughout The chapters on cancer of the uterus and breast, on the nose and nasal sinuses, and on chronic rheumatic disease are especially clear and informative The chapter on records and presentation of results is also useful Surprisingly there is no section on the treatment of salivary gland tumours

The diagrams, tables, and illustrations are as clear and lucid as the text This excellent book can be recommended not only to the radiotherapist but to all those who send patients to the radiotherapy department

Human Limbs and their Substitutes

Editors PAUL E KLOPSTEG, PH D, SC D, director of research, Northwestern Technological Institute, Evanston, Ill, PHILIP D WILSON, M.D, surgeon in chief, Hospital for Special Surgery, New York New York and London McGraw Hill 1954 Pp 844 96*s*

UNTIL lately the design, manufacture, and fitting of artificial limbs, and the training of amputees in their use, were in the hands of firms making such appliances and a few limb-fitting surgeons The craft had developed empirically, and though the product was tolerably satisfactory it was without a scientific basis The surgeon-general of the United States army determined at the end of the late war that his pensioners should have the best that man could devise, so he enlisted the aid of the National Research Council The council has carried out one of the most elaborate and comprehensive investigations ever made into a single aspect of human behaviour The scheme, ambitious in conception, and far beyond the scope of individual enterprise, is an outstanding example of the possibilities of research organised at national level and sponsored by national bodies It has covered fundamental research into every aspect of all the problems of the amputee, and it has called for the integrated work of orthopædic surgeons, anatomists, neurologists, psychologists, civil engineers, plastic engineers, physicists, and manufacturers This volume reports the results of seven or eight years' work by the different groups

There are chapters on the mechanics of muscles and of locomotion, new developments in artificial legs, arms, hands, and hooks, the technique of cineplasty, the electric arm, suction sockets, the prescription, alignment, and fitting of prostheses, the evaluation of new devices, and many others *Much of the work is highly technical, it reports basic observa*tions not yet directly applicable to the construction of prostheses, and some which, though still experimental, point the way for future development

Dr Klopsteg and Dr Wilson, an engineer and a surgeon, have done a magnificent job in presenting such a heterogeneous mass of material as a coherent story The [illegible] is indispensable for everyone concerned with [illegible] limbs, and no orthopædic surgeon can afford [illegible] the basic research in human physiology and what it reports

Textbook of the Rheumatic Diseases

2nd ed Editor W S C COPEMAN, O.B E, M.D F R C P, senior physician, Arthur Stanley Institute f Rheumatic Diseases, Middlesex Hospital Edinburgh London E & S Livingstone 1955 Pp 754 52*s* 6*d*

THE first edition of this textbook was published before cortisone and corticotrophin made their début In the second edition the place of these hormones in treatment is considered by several of the 26 contributors who form Dr Copeman's authoritative team

The book is a series of essays, and some overlapping has been accepted and encouraged, thus each section stands by itself as the considered statement of an expert surveying familiar territory, and not subjected to undue editorial restraint The reader in search of a complete picture of the treatment of rheumatoid arthritis must be prepared to wend his way from a general chapter on the disease to others on hydrotherapy, physical medicine, and orthopædics A minor criticism is the mixing of positive and negative reproductions of radiographs throughout the book, even on facing pages The difficult task of surveying the whole subject of the adrenal hormones has been attempted in a new chapter There are some misleading statements in this account, particularly on the effect of adrenal hormones on antibody production and on reactions of hypersensitivity The only work on antibody production cited is the old observation of a rise in titre associated with the lympholysis induced by adrenal stimulation This phenomenon has never been confirmed, and more recent and important work on the depression of antibody production by cortisone is not mentioned. There is some apparent confusion between the effects of cortisone on tuberculin sensitivity and on susceptibility to the spread of tuberculous infection In a short description of collagen diseases "hyaluronidase" is used where hyaluronic acid is intended, and fibrinoid degeneration is rather loosely defined Fortunately a clear and accurate account of connective tissue pathology is included in a separate chapter

This work has deservedly secured its place as a standard textbook, and the appearance of this up-to-date second edition is timely

Insanity, Art and Culture

FRANCIS REITMAN, M.D, D P M Bristol John Wrigl & Sons 1954 Pp 111 12*s* 6*d*

THE influence of a particular culture upon the artist productions of the mentally ill is a special case of tl more general problem of artistic creation in differei societies Dr Reitman has assembled paintings an drawings by psychotic patients in Mexico, East Afric Egypt, India, Ceylon, Japan, and New Zealand, in a these, of course, occidental influences have to be reckone with to some extent in the prevailing culture

The material was not large enough to allow quantitativ analysis, but the qualitative characteristics of schizophreni painting were present in the production of the Egyptian Indian, Sinhalese, and Japanese patients, though some features that would be indicative of illness in a European patient reflected normal cultural forms when they occurred in the production of the oriental patients Dr Reitman then examined the influence of the artistic medium by comparing psychotics' paintings with their needlework and scripture, and he expresses the surprising opinion that "in our present day cultural pattern there seems to be little to stimulate activity in any visual art other than painting" In succeeding chapters there are brief accounts of the lives of Alfred Kubin and George Morland in relation to their artistic activity, some reflections on drawings and paintings carried out "automatically" as in a trance or while doodling, and a somewhat irrelevant sketch of Mytton, the well known eccentric The book, which contains suggestive ideas about the diagnostic value and the complex sources of artistic production, would gain by a fuller consideration of some previous writings, such as those of Kreyenberg, Morgenthaler, and Pfeifer

Proceedings of the International Congress of Physical Medicine—The proceedings of this congress, which was held in London in July, 1952, have now appeared Copies (30*s* post free) may be had from the International Federation of Physical Medicine, 45, Lincoln's Inn Fields, London, W C 2

THE LANCET

Mental Nursing Analysed

Bethlem Royal Hospital and the Maudsley together orm a centre of teaching and research so outstanding hat one might suppose they would never want for nursing staff Yet the recruitment problems which re so acute throughout the mental service have affected them too, and in 1951 the board of governors of the joint hospital arranged for a job analysis of their nurses' work. Their aim was to gain information that would help them in formulating their nursing policy and training procedures and the results of the analysis (which was made in 1951–52) have led them to make considerable changes Believing that the findings can be of use to other mental hospitals, they now with great public spirit, present a condensed report[1] of this the first inquiry of its kind into the work of mental nurses Like the Nuffield[2] job analysis of the work of general nurses, it brings its shocks and if, in drawing attention to these we seem to criticise the practice of these hospitals it must be borne in mind that it is their *former* practice that is under discussion and moreover that the training given to nurses in them, even before 1951–52, was probably better than that given in many other mental hospitals now

The most striking finding of the Nuffield report was that three-quarters of the nursing in general hospitals was being done by student nurses, and this new report shows that in mental hospitals too, a large part of the care of patients falls to unqualified nurses

Nurses are classed as ward sister or charge male nurse; senior nurse (either a staff nurse or a student nurse in her last year of training who is second in charge the ward) middle-rank nurse; junior nurse (the oungest in experience on the ward) and part-time urse Their tasks are grouped under the headings are of patients supervision; household duties (among hich are included somewhat surprisingly, bedmaking nd the serving of meals and drinks); duty room work hat is, the writing of reports and notes) and reception nd management. At the time of the survey sisters pent the largest slice of their lives on the last of these 41% of their time at the Maudsley and 34% at Bethlem) he figures for care and supervision of patients by sisters n the two hospitals were only 12% (Maudsley) and 80% Bethlem) Senior nurses spent 15–17% of their time on eception and management but the amounts they pent on care and supervision of patients were strikingly ifferent in the two hospitals—22% at the Maudsley nd 58% at Bethlem Middle-rank nurses had a similar attern spending 7–10% on reception and management nd 48% (Maudsley) and 61% (Bethlem) on care and upervision Junior nurses spent only 5–6% of their ime on reception and management but 42–51% on are and supervision of patients The number of hours worked by part time nurses differed considerably in the wo hospitals Though some of them were trained nurses they spent much time on household duties (44% at Bethlem 57% at the Maudsley) At Bethlem most of their remaining time went on care and supervision of patients but at the Maudsley only a quarter of their time was spent in this way

From the standpoint of the hospitals, there was nothing much wrong with the arrangement whereby the nurses who spent most time with the patients were those of the middle and junior ranks, and (at the Maudsley) part-time nurses. Patients need sympathetic company, which kindly young people are quite able to supply, the technical aspect of treatment is in the hands of the doctors, and any junior nurses who have the care of patients recovering from physical treatment learn from their seniors what is required of them On the other hand, the young girl—and even the young man—without previous nursing experience may see the situation rather differently Lay people, among whom untrained entrants must be classed, are ill at ease with those they suppose to be mentally disordered, and the new nurse needs a brief course to orient her to her work—some guidance, for example, in recognising guilt and anxiety, and some notion of the ways in which these are augmented or reduced Admittedly, during her 8 weeks in the preliminary training school (P.T.S.) she would hear the sister tutor lecture (for about 1½ periods a week, usually on Saturdays) on various aspects of mental illness, but the official syllabus for the preliminary State examination, to which the course otherwise adhered contains no mention of psychology or psychiatry In any case, even at Bethlem and the Maudsley new nurses did not necessarily begin their training in the P.T.S but might reach it only after several weeks, or even months of work in the wards. To have to deal with mental patients without sufficient preparation must be for many people an alarming experience—not because the patients are alarming (they so seldom are) but because of the sense of inadequacy that ignorance engenders Can we doubt that this abrupt introduction to the work was among the chief causes for the loss of 65–70% of student nurses before the end of training most of them during their first year?

Apart from the lectures they attended in the P.T.S., student nurses were offered, during their first year in hospital, 24 lectures on anatomy and physiology by the medical staff, adequate revision classes (some optional, some compulsory) and 6 lectures on psychology from the sister tutor The famous Dr Arnold of Rugby wears in his portrait a puzzled expression which Lytton Strachey attributed to the failure of his boys to make headway in French despite half an hour's instruction in that language every week Do the sister tutors in our mental hospitals acquire a similar look? Or is theirs a look of despair, directed at the medical staff? For a full dress course of 20 lectures on psychiatry and 20 on neurology, from doctors, student nurses had to wait until their second year—and many of them did not wait In their third year they got, also from doctors, 10 lectures on normal psychology (surely rather late in the day), and 6 on child psychiatry and the sister tutor followed up each of these in a discussion period Thus in their second and third years the student mental nurses were having a formal educational diet relatively rich in the nutrients they had been needing all along In some ways however, it was a feast of Tantalus for their attendance at lectures often depended on whether or not they could be spared from the wards Lecture attendance, as a proportion of the possible or ideal, was 56% at Bethlem and 63% at the Maudsley over four years , and of those nurses who were absent, just under half were away for reasons accepted as unavoidable Naturally the student also got a good deal of practical and informal training in the wards, and it was in fact the firm intention at both hospitals that some of this should be given by the doctors Thus there were weekly “ ward talks ” in which the registrar or senior house-officer spent an hour discussing one or more patients with as many nurses as could be spared from the ward at the time But unfortunately at busy moments such engagements are liable to be cancelled, and audiences are seldom at full strength thus at Bethlem, in the year under review, only 53% of the possible number of talks had been given, and student nurses had attended only 32% of those provided for them Students certainly could not count on hearing an informative discussion on all of the cases which came under their care , and they had little opportunity to ask about them at other times for the job analysis shows that they spent only 1–2% of their time with doctors—usually in looking for a patient This need was to some extent met by another means of communication—the “ nurses' notes ” On the admission of a new patient, the registrar wrote his instructions on a sheet with this heading, and the nurse to whom the patient was assigned wrote on this sheet her observations on the patient's behaviour during the week The ward sister handed the notes to the registrar weekly, and he added his own notes and comments Fully used, this is a valuable device , but if (as sometimes) it is neglected the nurse loses interest, and her notes become desultory Registrars and senior house-officers, on appointment, were given a 2½-day induction course, which included a 30 minute talk from the sister-tutor on the part they were expected to play in the training of nurses But these occasions, too, may have helped to stamp the sister-tutors with a look of Dr ARNOLD

---

[1] The Function and Training of Mental Nurses. By A. N. Oppenheim with the assistance of Henry Froman London Chapman & Hall on behalf of the Bethlem Royal and the Maudsley Hospitals 1955 Pp. 85. 12s 6d

[2] The Work of Nurses in Hospital Wards London The Nuffield Provincial Hospitals Trust 1953 See *Lancet* 1953, i, 370

The doctors, however, were not entirely to blame if they occasionally displayed only a lukewarm interest in nurse training , for the nursing candidates were of very uneven quality Actually of those who asked for an application form, 70% never filled it in and sent it back , 40% of those who did send it had to be rejected , and two-thirds of those accepted dropped out, most of them during their first year Doctors with more urgent things on their minds may well grudge spending teaching time on young people who are never going to make nurses Nevertheless these things cut both ways a high rate of wastage is a bad advertisement for mental nursing , and a doctor's casual attitude towards nurse training may lose some promising, as well as some unpromising, students In the case of a male student nurse already perhaps worried about the financial prospects, it may make the difference between staying and going , and the disappointment of the good and promising nurse who gives up training may deter many other likely candidates

The survey should encourage mental hospitals elsewhere to consider how far, as employers, they now show themselves skilled in industrial psychology An application form which puts off 70% of candidates might well need revision , and it can be very unwise to plunge an adolescent student, without due preparation, into an environment which is bound at the outset stressful If her further experience of hospital to build up her morale—and that pretty quickly—she is naturally going to leave The makes the practical suggestion that every su nurse might be attached to a psychiatric firm would not only help her to think of herself as part team, but might help the doctors, too, to think of in this way, and to treat her accordingly

Chelating Agents

TREATMENT of metallic poisoning by chelat agents was introduced a few years ago in the Unit States by BESSMAN and his colleagues,[1] and ma reports have since testified to the value of this metho Earlier this year we published an account of a ca of lead poisoning in a child successfully treated by th chelating agent, calcium disodium ethylenediam tetra-acetic acid (E D T.A)[2], and on a later page this issue Professor BROWNE describes two cases adults

Chelating agents (χηλή, a claw) combine wi certain metals to form firm complexes They ha this property because they contain nitrogen or oth atoms capable of donating electrons to metals wh require these in order to complete their atomic co figuration The resulting ring structures are ver stable, and the metal is non-ionised and thus do not show its usual chemical or physiological activit Hæmoglobin is a chelated complex containing iro Chelating agents are useful in medicine because th metal complex formed is soluble, is readily excret by the kidney, and is non-toxic the action of chelating agent in metallic poisoning might be likene to that of a policeman peacefully escorting a troubl maker from a political gathering The affinity for th chelating agent varies between the different metals and one metal which forms a stable complex ca displace a second metal whose complex is less stabl This is the basis of the therapeutic use of calciu disodium E D T A in lead poisoning The disodiu salt itself is unsuitable for the treatment of heav metal poisoning, because it very readily combin with calcium,[4] and may thus provoke dangero hypocalcæmia But the affinity of lead for E D T is greater than that of calcium, so administration o the calcium chelate results in lead being safely remov from the tissues

Rational therapeutic use of calcium disodiu E D T A requires knowledge of the pharmacolog of this agent It can be given by mouth, since it absorbed to some extent from the gut without significantly chelating metals present in the alimentar tract[5–7], but absorption is greater when it is giv subcutaneously[8,9] or intravenously E D T.A rapidly excreted unchanged in the urine, about 90 of the dose being eliminated within six hours aft intravenous injection[10] At the pH of the bod 1 molecule of lead is bound to 1 molecule of E D T If the chelating agent were fully efficient in the bod

3 millimols of calcium E D T.A, equivalent to 5 g, would produce excretion of about 260 mg of lead The figure observed by **Bessman** et al[8] was in fact only 1 8 mg of lead representing an efficiency of 0 7% The probable reason for this low efficiency is that lead is bound in the tissues to sulphydryl groups, and although the affinity of lead for calcium E D T.A. is greater than it is for the SH groupings, these are much more numerous in the tissues **Bessman** et al found that increasing the dose of calcium E D T A. did not increase the excretion of lead probably because much of the larger dose is excreted in the urine before it can be brought into equilibrium with the tissues This would suggest that the best way to give calcium E D T.A in acute lead poisoning is by slow continuous infusion or by repeated infusions, and hitherto the latter method has been the most commonly used A single dose need not exceed 0 5 g, this amount is usually given dissolved in about 200 ml. of saline over a period of two hours, and infusions are repeated every eight or twelve hours for about five days Subsequent courses of similar duration are given, divided by intervals of a few days Administration of the chelating agent is rapidly followed by a large excretion of lead chelate in the urine, with a daily output of up to 4 mg, the blood lead level falls steadily, symptoms of acute lead poisoning are rapidly relieved[11], and over a period of days coproporphyrin disappears from the urine, the stipple cell count in the blood falls to zero, the lead line in the gums disappears, and the dense band at the metaphysis of the long bones of children becomes no longer demonstrable radiographically The oral preparation is probably best reserved for the treatment of less acute cases[8] There is evidence that calcium E D T.A can be given safely the vital elements iron, copper and cobalt, do not displace calcium from the calcium E D T.A complex serum levels of sodium and magnesium are not seriously deranged[7], and the serum calcium level itself remains unaffected[4] The lead E D T.A complex has caused few side-effects[7]

E D T.A. has also been used in the treatment of poisoning due to other heavy metals for example, **Maloof**[12] found that an ointment containing calcium disodium E.D T.A is of value against the indolent chrome ulcers seen in the tanning industry But this agent may have *further* uses In laboratory animals it removes radioactive isotopes, such as yttrium[13]—a property that *may prove* clinically important. In a different approach, an attempt has been made to "chelate" out of the body calcium which has accumulated in pathological processes such as nephrocalcinosis, otosclerosis, peripheral vascular disease and calcified mitral stenosis[14] The theoretical justification for such a measure has not yet been fully worked out, nor *is this measure* free from hazard In two cases of hypercalcæmia treated with sodium E D T.A by **Dudley** *and his* colleagues[15] the patients died and necropsy revealed severe damage in the proximal convoluted tubules of the kidneys, which **Dudley** et al believe was probably a result of the therapy

In E D T.A. the physician has acquired a valuable and safe means of treating acute and chronic poisoning by various heavy metals, and a chemical tool which, if used judiciously, may lead to better understanding of many metabolic problems

Ascites

The development of *ascites in portal cirrhosis* of the liver depends on several factors, but the movement of fluid from the capillaries into the peritoneal cavity is controlled primarily by hydrostatic and colloid-osmotic pressures[1] Tending to force fluid out of the vascular compartment is the capillary blood pressure and drawing it out is the osmotic pressure of the proteins in the interstitial and ascitic fluid An opposing force is exerted by the osmotic pressure of the plasma-proteins, and by the intra-abdominal hydrostatic pressure

Portal cirrhosis increases the resistance to blood flow through the liver[2], and this in turn increases *the portal venous* pressure, which has *been measured* directly at operation, by determining the pressure in portal collateral veins as they run up the anterior abdominal wall, and by passing a catheter via the right atrium into a hepatic vein. If the catheter is inserted until it occludes the vein the pressure recorded agrees closely with the portal venous pressure—the technique is analogous to measuring the left atrial pressure by wedging a catheter in a pulmonary arteriole[3] By this means **Sherlock** *and her* associates[4] found that the portal venous pressure averaged 7 mm Hg (range 2·6–11 2) in healthy people and was raised *to* 22 (range 15 6–35 2) in 11 patients with cirrhosis By *itself* increased portal venous pressure does *not* cause ascites Ligation of the portal vein in laboratory animals and during removal of the pancreas in man *does not* produce ascites in animals ascites follows only if plasmapheresis is carried out in addition,[5] and *in* patients with extrahepatic portal obstruction ascites develops only when hæmorrhage from œsophageal varices reduces the plasma protein level, when the proteins are restored to normal *the ascites disappears* although the *portal hyper*tension persists Thus a reduction in plasma-proteins as well as *portal* hypertension is necessary for the formation of *ascites*, and in cirrhosis hepatic synthesis of plasma proteins is impaired **Post** and **Patek**[6] have found *fairly close* agreement between the plasma-albumin value and the presence or absence of ascites, the critical level being about 3 1 g. albumin per 100 ml., below which ascites is usually present

In addition to these *two main factors others are* involved, and, although some workers have sought to show that these are primary, most believe that they operate secondarily to the changes in body water and electrolytes that follow the accumulation of several litres of additional extracellular fluid This fluid is derived from the vascular compartment, and unless salt and water are retained the plasma volume will become seriously reduced Thus ascites is associated with a pronounced reduction in the urinary excretion of sodium Since low sodium excretion is at the same time found in saliva, sweat, and fæces and can be reproduced by administration of deoxycortone, it has been suggested that secretion of a mineralocorticoid hormone by the adrenal cortex increases in response to the threat of plasma sodium depletion LUETSCHER and JOHNSON[7] have now confirmed that in cirrhotics with ascites increased amounts of a potent sodium-retaining hormone, aldosterone, are present in the urine In experimental ascites in the dog removal of the adrenal glands is followed by profound sodium diuresis and disappearance of the peritoneal fluid[8], and MARSON[9] has reported a similar response in a cirrhotic patient subjected to total adrenalectomy In addition to aldosterone other adrenocortical steroids may play a part in the conservation of sodium Although the plasma level of 17-hydroxycorticosteroid compounds is not abnormally raised in cirrhosis, there is good evidence that they are not metabolised at a normal rate by the damaged liver[10] Thus the proportion of steroid present in the plasma in an active form, rather than as an inactive conjugate, may be greater than normal although the total amount of unconjugated and conjugated hormone may be no greater than in health Since the plasma-sodium level is not raised in patients with ascites there must be increased retention of water in parallel with the sodium retention Some workers[11] claim to have demonstrated increased amounts of an antidiuretic substance in the urine of such patients, and have suggested that increased secretion, or decreased destruction, of the posterior-pituitary antidiuretic hormone may have a primary rôle in the pathogenesis of ascites Unfortunately the techniques for estimating the antidiuretic hormone in urine are imperfect, and in a careful study WHITE et al[12] have found that cirrhotic patients metabolise antidiuretic hormone at the same rate as healthy people, and other workers with improved techniques have not found that the plasma level of antidiuretic hormone is raised[13] Diminished renal blood-flow has been reported in some[14] but not all[15] patients with ascites, and it seems likely that this, like increased secretion of aldosterone, is a secondary event depending on reduction in effective plasma volume as a result of movement of fluid from the vascular compartment into the peritoneal cavity It is wrong to think of ascites as a static collection of fluid separated from the vascular compartment Studies with radioactive isotopes[16] have shown that within the course of an hour half the ascitic fluid is exchanged with plasma fluid, and albumin given intravenously to raise the plasma osmotic pressure fails to achieve its purpose because the protein passes rapidly into the ascites[17]

Treatment is aimed at improving liver and sometimes in ascites of sudden onset the may lose a lot of fluid when put to bed on a balanced diet containing 80–100 g protein however, little can be done to improve the state the liver, and treatment is then directed sodium retention by restricting the intake of salt less than 1 g daily[18] An initial paracentesis hasten relief, but repeated paracenteses are to be avoided on account of the large amount of lost to the body If the ascites is not controlled a low-sodium diet alone, mercurial diuretics ammonium chloride should be given twice weekly

BCG

THE problems associated with B C G vaccination increasing A preliminary assessment of the vaccinat programme in India, sponsored by the government India and carried out by W H O,[19] *underlines* important points First, owing to the high prevalence non tuberculous tuberculin sensitivity in certain the uninfected cannot be accurately distinguished the infected A varying proportion of children have not been infected by tuberculosis are being exc from vaccination, the proportion probably being as as 50% in some areas Raising the arbitrary limit f positive reaction would bring in more of these but it would also involve vaccination of more of already infected Secondly, the degree of skin after vaccination was found to vary considerably, and many instances was much lower than had been exp It was thought that this could not be due to a rac incapacity of Indian children to develop high sens or to impairment of the vaccine's potency by expos to light Some other factors in its handling or ad tration must have been involved, or there may have inaccuracies in the tuberculin testing The potency tuberculin, like that of B C G, decreases with exposure sunlight[21] *Exposure to subtropical sunlight of a 5* dilution of P P D in clear glass bottles for twelve ho impairs its potency by about 80%

It is important to know what degree of sensitivit being produced by vaccination In vaccinated guineap the length of survival after infection by virulent bacill related to the size of the post vaccination tuber reaction[22] As the dose of living B C G is increased, th is not only an increase in the size of the vaccination le and the subsequent tuberculin reaction, but also survival after infection Heat killed B C G, on the ot hand, leads to small reactions and short surviv although the vaccination lesions are as large as wh living B C G is used The size of the vaccination lesion clearly not a reliable guide to the immunity induc but that of the post vaccination tuberculin reac may be -

The frequency of suppurative lymphadenitis in newborn is causing some concern There are reports an incidence as high as 23% in Taiwan[23] and of 12% in this country[24] The frequency of local absces the site of injection depends largely on the technique vaccination, the deeper the injection the greater risk of an abscess The presence of lymph nodes is apparently unrelated to the severity of vaccination lesion[23] On the other hand, it is clo

lated to the dose of the vaccine and the age of the ild[25] Gaisford and Griffiths[24] found that the incidence as reduced from 11 7 to 0 3% by lowering the dose B C G from 0 2 to 0 05 ml But since the degree immunity may be directly related to the dose of C G[22] the dose should be as large as possible.

A much more serious complication of vaccination has een recorded Meyer[26] reports from Denmark the death f a 9 year-old boy from widespread tuberculosis involv ng the lymphatic system two years after vaccination hirteen cultures of tubercle bacilli were obtained at ifferent times from different lesions before and after eath These were found to be indistinguishable from C.G no normally virulent bacilli were isolated The onclusion that the disseminated tuberculosis and death ere due to the B C.G vaccination is inescapable A imilar case has occurred in Norway[27–29] A man aged 24 ho had been vaccinated four and a half years previously ied after a protracted illness during which there were uberculous lesions in the lymph nodes bones lungs rinary tract, and rectum *Bacilli indistinguishable from* C G were recovered during life and from several organs fter death There is no evidence in either case that the atch of vaccine used was in any way abnormal There ave, of course been previous reports of deaths attributed B C.G —such as those in Hungary in 1930[30 31]—but n none has the evidence been completely convincing t must now be admitted that B C G can cause dis eminated progressive disease in man without any pparent change in its properties in the laboratory ut it is also clear that this must happen very rarely ideed Irvine[32] in 1949 estimated that if all the uspicious cases were included the incidence was less than per million *Between 1951 and 1953 16 million* were accinated in the mass vaccination campaigns of W H O lone[33] and no deaths have so far been reported.

These two deaths do not by themselves give cause to lter the current practice of B C G vaccination Indeed ere is reason to wish that it were more ready obtainable this country by doctors who want to use it At present s import and distribution are closely controlled by e Ministry of Health and only those belonging to rtain specified groups can be vaccinated Such a utious policy may be correct if vaccination is regarded a public health measure But B C G vaccination also oncerns individuals Other protective inoculations are controlled whether or not they are considered by the inistry to be desirable The doctor is free to decide hether the patient for whose health he bears a more rect responsibility than do the public-health authorities, ould be inoculated against, for instance yellow fever e fact that such inoculation is wholly unnecessary in is country is irrelevant But he cannot decide whether e patient should have B C.G If control were removed is unlikely that B C G would in fact be used much more tensively than at present But an important principle ould have been upheld

A NEW MORPHINE ANTAGONIST

Most *clinicians have had to face the problem of* e patient with intractable pain who needs increasing es of morphine which cause severe depression. Shaw d Shulman[34] have given a synthetic morphine tagonist *2–4 diamino 5 phenyl thiazole by injection* doses of up to 40 mg to five patients in the terminal ages of carcinoma. This had the effect of relieving the severe respiratory depression and narcosis induced by the large amounts of morphine which these patients were receiving—up to gr $1^1/_2$ (24 mg) in a single dose—without impairing the analgesic action No disagreeable side effects were noted. This compound differs from nalorphine in that it does not provoke withdrawal symptoms in patients already receiving morphine

THE FIRST TEN MINUTES

The notable reduction in infant mortality during late years has been largely due to decreased mortality in the group aged 1–12 months, as has been shown graphically by Dr Morris and Mr Heady[1] Donald[2] contends that many deaths in the first month are preventable In the past most such deaths were attributed to prematurity, and some progress has been made towards averting premature delivery (Hamlin's work[3] on the prevention of pre eclampsia is a notable contribution) But lately attention has been directed to improving the survival rate of premature babies, in the belief that prematurity is sometimes inevitable Potter[4] has laid down a challenge to clinicians by refusing to accept without close scrutiny prematurity as a cause of death per se in babies weighing over 1000 g (2 2 lb) She states emphatically that the commonest cause of death in premature babies above this weight is hyaline membrane, and though our know ledge of this condition is still imperfect it is probably to some extent preventable and treatable.[5]

If the neonatal survival rate is to be increased then methods of resuscitation and of care of the newborn must be improved One measure which has brought great benefit is the intra gastric administration of oxygen[6] which has been widely practised with excellent results. Atlee[7] urging the need *for closer attention to* the infant in the first minutes after birth writes

> What seems to happen so often is this : immediately the baby is born its cord is clamped and cut, it is handed to a nurse who puts it in a cot at the far corner of the delivery room or in one actually outside the delivery room, while the obstetrician proceeds to sew up the episiotomy Presently someone comes in to say that the baby is either not breathing well or has stopped breathing After that a nerve-wracking 10 or 15 minutes of resuscitation ensues, until the grey blue baby responds sometimes it doesn t

Atlee admonishes us not to let the baby out *of our* hands until it is breathing properly and has a good pink colour all over its body ' He believes that complete drainage of amniotic fluid from the respiratory tract is essential and to achieve this he holds the newborn baby upside down for 5 minutes Gibberd[8] too emphasises the importance of complete removal of amniotic fluid Atlee remarks that the umbilical cord should not be severed until the *infant has received all the* blood from the placenta The advantages of this are clear and are especially great in the case of the premature baby He also suggests that the cord should be tied with tape *thus averting the risk of cord hæmorrhage* associated with clamping He likes to have beside the delivery bed a light carriage in which the baby is kept under the eye of the obstetrician for the all important first few *minutes.* Duckman et al[9] *point out that the baby* should lie at a lower level than the mother Atlee is in fact urging a change of emphasis in the third stage of labour He suggests that obstetricians have concentrated too *closely on the condition* of the mother because of fear of hæmorrhage Nowadays with recourse where necessary to ergometrine the obstetrician should be able to control the third stage without losing sight of the child

TALK, TACT, AND TREATMENT*

RICHARD ASHER
M.D Lond, F.R C P
PHYSICIAN TO THE CENTRAL MIDDLESEX HOSPITAL

I AGREE with Dr Balint that many doctors select the physical and eschew the psychological factors in their patients' illnesses I know I am as guilty of this as are most physicians All the same, we have some excuse, some reason, for being frightened or suspicious of the subject of psychiatry even though we know that psychological factors are important

Psychiatry seems to me to differ from medicine in having a closer resemblance to religion Beliefs and dogmas are promulgated by certain masters—Freud, Adler, Jung, and so on—and these ideas are believed more from reverence of their originator than from repeated experimental observation Secondly, the language of psychiatry, like that of religion, is often esoteric and concerns itself with concepts and abstractions whose exact meaning is less precisely comprehended than are the majority of medical concepts If for a moment we consider the dynamic formulation of both objective and subjective thought fantasy, then cognitive functions can easily become projected into an integrated but psychically barren wish fulfilment That last high-sounding sentence, as I hope you noticed, has no meaning whatever and is pure nonsense, but I wrote it to demonstrate that with the aid of abstract terms it is easy to parade such a brave show of words in front of one's thoughts that it is extremely difficult to see if there is any idea behind them, and it is equally easy to take a small idea and wrap around it such a glittering mantle of language that it can dazzle the unwary into applause Thus although much wisdom is written by psychiatrists, the nature of the subject and its language make it hard for the ordinary doctor to distinguish the profound from the profuse

Another difference between psychiatry and medicine is that it is easier to prove the correctness or otherwise of medical ideas Modern medicine consists to a large extent in debunking the ideas erroneously held by others We used to treat bloodless limbs by warming them—now we cool them, we used to treat bleeding ulcers by starving them—now we feed them With psychiatric beliefs experimental proof is much harder I have recently been reading the views of psychiatrists on the syndrome of depersonalisation Gordon describes the syndrome as a converted representation of hidden or repressed emotional consciousness by special determination Perhaps he is right, but Schilder stresses the shift of the libido and its partial concentration on a scrutinising tendency Here I find myself asking how one can tell if a libido has shifted and what means are there of assessing its scrutinising tendency Sodger says it may be an attempt to escape psychic castration Perhaps it may, but for a physician the phenomenon of psychic castration is so much harder to understand than is its physical counterpart Wittels says it is caused by an unusually large number of phantom figures leaving the ego undecided about which figure should be acknowledged as its representative As a physician I find myself in complete ignorance as to what is a normal healthy number of phantom figures, would five or six, for instance, be considered excessive ?

I have made these few comments to show how sea the physician feels when he looks at ps theory, and how bewildered he becomes if he how to prove which theory is right

After this rather lame excuse for the ph neglect of psychiatry I will get down to the body of my subject

THE DOCTOR AS A DRUG

Dr Balint spoke of the discovery of his seminar th by far the most frequently used drug in general was the doctor himself "it was not only the med in the bottle, or the pills in the box, that mattered the way the doctor gave them" Here I am in agreement In the words of a popular song "It's what you do, but the way that you do it" Dr continuing the analogy of drug and doctor, regrets textbooks and lecturers teach us the way to use but not the way to use ourselves Admittedly the we deal with our patients, and especially how we to them, is about the most important part of our but can it be taught ? I doubt it It can be experience and to some extent by watching great d handling their patients, but it cannot be taught pharmacology All the power of tongue and pen, all the wisdom of textbook and lecture, can never a doctor the knowledge of when to probe and when leave alone, when to chide and when to reassure, wher speak and when to keep silent They are private with a different solution for every one of the m permutations of personality involved between a and his patient

I believe the analogy between drugs and doctors false one there is such a great difference between Drugs can be standardised and doctors (thank cannot —If you give a man a pill there are only things he can do with it he can swallow it or he throw it away If you give a man explanation or there are uncountable ways of giving it and even ways in which it can be taken Dr Balint tilts at suggestion that common sense and experience will the doctor know how to prescribe himself (in fact ho talk to his patients) and says the shallowness of solution is apparent when it is compared with the and detailed instructions with which every new introduced I think here again the analogy of drug doctor has been extended too far On the best way to drugs there is a certain measure of agreement though individual patients may react differently, but the best way to speak to patients there is not some agreement on the correct dose of digitalis f ten stone woman fibrillating at 120 beats per minute far less agreement on the correct type and dose of versation for a ten-years unhappily married vociferating at 120 words per minute Moreover there only three or four kinds of digitalis, but kinds of doctor, and even more kinds of women

No the prescribing of ourselves cannot be taught, partly instinctive, partly imitative, and partly by experience I do, however, consider it to be enormous importance and I propose to say some on the subject of conversation with patients

TALKING TO THE DOCTOR

Why does the patient want to talk to his doctor ?

First there is the natural desire for cc Many people simply want a pleasant chat, but going along to the local public-house for a drink of and a chat with the landlord they go along to the hospital for a drink of medicine and a chat with doctor The use of a doctor for this purpose is sary, and a pleasant gossip over a cup of tea with atients is equally satisfying Indeed one enlightened hysician tried the experiment of arranging outpatient ssions where the patients did not see the doctor at all less they specially asked for him †, this experiment as a great success. Moreover, despite the present high rice of tea, a cup of tea is cheaper than a bottle of edicine and far less likely to do any harm

---

* From an address to the Medical Section of the British Psychological Society, forming a sequel to the chairman's by Dr Michael Balint published last week 83)

Another reason why people want to talk to doctors is get sympathy—they do not want help or advice they ant someone to know how much they are having to ear A vicar's wife told me once that much to his istress, parishioners were always wanting to show their lcerated legs to the vicar This was done not for spiritual ealing but that he might realise the extent of their ufferings It is a fact that it is easier to bear a heavy urden if that burden is visible to others. Doctors are old of all sorts of troubles—financial, domestic or ersonal—which are beyond their powers to relieve but ll the patient is seeking from them is some remark of the ind: I don t know how you put up with it all," or I think it s wonderful the way you manage to carry n ' Almost anything can be borne if someone thinks ne is wonderful

Some patients, unlike those I have just mentioned ome for advice They have problems which are soluble, nd they need, not sympathy, but a *suggestion as to* hat is to be done or not to be done Though it sounds aradoxical to say so I believe the advice given is often nmaterial The conversation helps the patient to make p his own mind, irrespective of the wisdom of the advice iven Only when he is strongly advised to do A does the verage person realise how much wiser it would be to o B

Other types of patient come not to see what the doctor as to say but already firmly decided on what he will say hey come, not for advice but to get medical backing or their own views. Whatever the doctor says they ill report that he confirmed their opinion If Mr ones says 'It s that terrible smell in the factory that s iven me this chronic stomach ' and the doctor says I m sorry to hear that ' he will be reported as saying The doctor said the fumes had poisoned my whole stem ' Or if Mrs Jones says Tommy got St Vitus ance because they caned him at school " and the doctor ays 'Hmmn she then reports this to her friends as The doctor said he d never seen such a terrible ase and his nerves ll never be the same after that aning '

In similar fashion those who wish to attribute illnesses tonsils air raids too much work at school damp alls, or being dropped as a baby will seek medical upport for their opinion Many of these people deserve ur sympathy and understanding Surely it is infinitely ore satisfying for them to rage at a bomb or to impugn tonsil than to try to accept that some illnesses have no ertain cause Fate is such an insubstantial target for lame compared with a damp wall a large tonsil or a ad smell

When a patient is seeking confirmation for an erroneous elief which does no-one any harm and gives him the omfort of something to blame it is questionable if much ood is done in correcting him but when he is out for ood, seeking ammunition with which to assail his nployers, his doctor or his hospital, then it is a very fferent matter This is an age of compensation not ly out of loyalty to our colleagues should we decline vitations from patients to criticise each other but for e good of the patients themselves The psychological rm done to patients by long-continued litigation is ten more extensive than the expense and trouble caused the medical profession

TALKING TO THE PATIENT

Having described some of the reasons why patients come to talk to doctors I now consider some of the ways a doctor can talk to his patients. As I have remarked, this is not a subject that can be taught, but it can be discussed, and I will consider it under various headings

First, *impressiveness* The impression a doctor makes *on his patient* is as important as the pharmacological action of the treatment he gives, but a doctor wishing to impress a patient must consider first whether he is *benefiting him* It is a good thing to give the patient confidence, but a doctor can pay more attention to the impression he is making on the patient than to the good he *is doing him* *Not only the way a doctor speaks* but his gestures, his manner and his smile all play their part There are also accessory aids—a book written by the doctor himself lying carelessly on the desk the use of a large shiny motor-car and chauffeur or (less expensive but quite effective) the skilful manipulation of a really thick pair of horn rimmed glasses Before using these adjuncts the doctor must consider whether he is trying to comfort himself or the patient It is a greater medical triumph to leave the patient feeling better but thinking little of the doctor than to leave him worse but deeply impressed

Secondly *tolerance* For a successful doctor patient relationship the doctor should try to achieve a level of tolerance and placidity nearing that of a saint He must be free of prejudice and not let the patient or his relatives irritate him Most of us have some foible, some little thing that rubs us up the wrong way I knew one children's doctor who could not bear mothers who overdid the word 'little" as in the sentence "He draws up his little legs, doctor and his little face is all screwed up when he passes his little motion I admit myself to an instinctive antipathy to patients who arrive for consultation chewing toffee or gum and also to patients who call me "Doc Such prejudices can and should be avoided The doctor's approach should not be 'Do I like this patient?" but 'Can I help this *patient?*" Experience will teach that many irritating mannerisms are caused by shyness and not by any desire to provoke for instance the patient who remains *apparently* buried in his newspaper when the doctor arrives at the end of his bed is rarely reading it he is probably assuming nonchalance because he is nervous.

Thirdly *lucidity* Misinterpretation of what the doctor says is so easy for the patient Many a doctor who has given an explanation on which he prides himself would be disconcerted to learn the retailed version of his carefully chosen words. One lady told me she had taken her boy to hospital where the doctor looked down his throat and told her the ear drum had grown right into the throat and was hanging out like a sausage He cut it off and said if he'd been five minutes later the child would have been dead I often wonder what he really said *I feel it cannot have been very clearly put*

Another example Last week a woman attending my hospital for her gastric ulcer assured me the house-physician had provided her with a new medicine which consisted of a strong solution of rubber dissolved in orangeade which was designed to fill up the cracks in the ulcer and set. This purpose she told me had been achieved

Both these patients were deluded but delighted but harmful *misinterpretation of doctors* remarks is even commoner That is why lucidity is so essential. It is a difficult art to cut one s explanatory coat according to the intellectual cloth provided by the *patient* and it must be especially hard for psychiatrists to word their interpretations without ambiguity because the is even harder to explain than the body

---

† Bourne W A *Lancet* 1950 i, 127

Fourthly, *confidence* Confidence is an infectious thing—the doctor who possesses it is the doctor who can give it to others It must be sincere It is not much use pretending you are sure when you are not—the patient can tell Confidence is invaluable because if you are certain you are right and if you can convince the patient that you are right then whether you really are right or not often makes very little difference Yet the doctor should not assume omniscience I have a notion that doctors do not often enough say "I do not know" It is better to tell a man confidently that you don't know than to tell him unconvincingly that you do Patients can appreciate sincerity and truthfulness more than some people realise

Another quality that helps a doctor deal with people well is *unhurriedness* To give a patient the impression you could spare him an hour and yet to make him satisfied with five minutes is an invaluable gift, and of much more use than spending half an hour with him during every minute of which he is made to feel he is encroaching on your time I do not know if this special kind of unhurried placidity can be acquired purposely, but it is a most enviable faculty to possess

WHEN TO SPEAK

I now pass from the question of how to speak to the question of when to speak—in this case I mean when to probe beyond the purely physical side of a patient's illness Physicians see a large number of patients whose symptoms are purely physically caused and respond completely to physical treatment These require nothing except a prescription and a word of explanation Then there are patients whose symptoms, although organically caused, seem to be giving them more distress than is warranted by their severity Here it is well worth finding out what the patients' private beliefs about their symptoms are Fear of a more severe disease than the one affecting them is in my experience a common reason for so called functional symptoms Many a young woman may complain of mild aches and pains which by themselves hardly worry her enough to be noticed, but because she has known somebody crippled with rheumatoid arthritis these symptoms cause her profound anxiety which itself provokes the symptoms further Such women rarely mention their fear until it is sought out, but it is well worth seeking There is often a sigh of relief and magical disappearance of symptoms when the patient is reassured that her fears are groundless It is also just as common to find a man with unaccountable anxiety from minor symptoms because he has a fear of cancer Here again the dread of cancer is elicited only by tactful inquiries I think it is wise to ask all patients if they have any ideas about the cause of their symptoms and also to find out if they have any friend or relative suffering from a disease which they themselves fear Strangely enough, those who have a dread of a disease seem rarely to be the people who suffer from it, so the proportion of cures by reassurance in this group is high

Another type of patient where some probing may be rewarding is the hypochondriac—the patient who makes a hobby of doctors and drugs The woman who keeps a diary not of social functions but of pelvic functions, the woman who instead of taking up canasta takes up her bowels and who patronises the great colonic laundries of Harley Street If the doctor by his talk and his tact can interest her in the world outside instead of the intestines inside he will have achieved something really worthwhile

CONCLUSION

The truth about doctor-patient relationships is, I believe, almost impossible to ascertain We doctors know what our patients think of us and rarely learn what effect our talk, tact, and treatment have "He was so enthusiastic I didn't like to offend him commonly the attitude of the patient

Occasionally we get glimpses of the truth when overhear a conversation on top of a bus or when pati remarks are relayed to us by a friend (or more likely enemy), but in the main we remain ignorant, perhaps it is happier that we do so

---

ESTIMATES FOR 1955-56

The National Health Service estimates[1] for 19 allow for an increase of £24,154,770 in net exp on the service (including Civil Defence services England, Wales, and Scotland Gross exper estimated at £537,888,365, compared with £511,73 in 1954–55, and appropriations-in aid at £74,518, compared with £72,522,350

The estimated gross expenditure is distributed follows

	£
Hospital, specialist and ancillary services	345,501
General medical, dental pharmaceutical, and supplementary ophthalmic services	149 471
Grants to local health authorities	23,506,
Training services, &c	1 686
Broadmoor Institution and State mental deficiency hospitals	1,682
Liabilities arising from the establishment of the service	5,10
Superannuation	8 006
Civil Defence services	1 [illegible]
Other services	705,
	£537,888,

The £345,501,315 estimated expenditure on the pital services is made up as follows advances to (capital account), £12,300,000, advances to (revenue account), £320,000,000, directly a hospitals, limb fitting centres, &c, £1,887,315, expenditure, £11,314,000

Estimated expenditure under most divisions shows an increase the largest is under advance boards (revenue account) where the increase is £20,5 Other increases include £2,312,000 for general me services (total £61,802,000) and £1,034,000 for dental services (total £27,537,000) The estimate Civil Defence services represents a reduction of £700 on expenditure in 1954–55

These estimates make no provision for the hos building programme announced earlier this year, e ture on which in England and Wales is expected amount to £7½ million in 1956–57, and to £10 in 1957–58[2]

Net expenditure by the Medical Research C in 1955–56 is estimated at £2,186,160, compared £1,974,869 in 1954–55—an increase of £211,291 the general expenses account estimated gross exp of £2,235,184 is made up as follows administ and central expenses, £95,292, National Institute Medical Research, £392,053, research units and ext scientific staff, £1,340,647, special grants to tions, &c, £184 242, temporary research grants training awards, £222,950 Under the building account, the cost of new building is shown as £84 and the cost of special apparatus as £16,100, a total of £100,100

Before Our Time

JAMES PARKINSON

Born April 11 1755

James Parkinson, whose *Essay on the Shaking Palsy* peared in 1817 was born in Hoxton lived all his life ere and was buried at the parish church of St Leonard's e term Parkinson's disease is now used throughout e medical world and the words ' Parkinsonism ' and Parkinsonian " have been added to the English nguage but Parkinson himself has been " forgotten the *English* and by the world at large "[1]

THE FAMILY

His father John Parkinson was a surgeon in practice Hoxton Square and he was the eldest of three children is sister Mary Sedgwick (born Jan 11 1763) married ohn Keys and his brother (born March 5 1761) died young man He married in St Leonard s Church, on ay 12, 1781 Mary Dale who is believed to have been e daughter of John Dale, a silk manufacturer who lived Charles Square Hoxton Six children were born of the arriage[2]

John Parkinson father of James, became a diplomate the Company of Surgeons soon after the surgeons parated from the Company of Barber Surgeons and 1775–76 he was anatomical warden under the master professor of anatomy He practised at no 1, Hoxton quare for many years until his death A memorial one is still visible affixed to the wall of the verger's ouse in the precincts of St Leonard's Church Shore itch and the inscription John Parkinson, surgeon te of this parish died 10th January 1784, aged 50, ' is ill readable though the epitaph below is undecipherable No 1 Hoxton Square is a corner house on the south est corner of the square and it was still standing in 1910 It had three storeys and a basement with a two-storeyed uilding behind it having an entrance on to the side street, nd behind this a single-storeyed room that might have rved as a shop[1] Nothing exists today except the old front llings the house was demolished many years ago and a ctory now occupies the site Parkinson in his will refers to e contents of his shop and it is probable that he kept an en shop for the sale of medicines, which would enable him charge for those he dispensed himself The house was never ned by the family though they had occupied it for so many ars the owner being a Joshua Jenning The whole of the quare which was built in the middle of the 18th century as owned at one time by Israel Wilkes father of the notorious ohn Wilkes.

Charles Square and Hoxton Square were the two best sidential areas in Hoxton and the Parkinson family had as eighbours the vicar of St. Leonard s Church, another surgeon, wyers tradesmen and several distinguished Nonconformist ivines Today the only residents are the vicar of St Leonard s hurch and the clergy of St Monica s Roman Catholic Church. early all the other buildings are furniture factories. Some of the buildings were destroyed in air-raids but the ancient trees in the centre still flourish and the garden is well kept Two other buildings in the square in Parkinson s time were the Hoxton Square Coffee House and a Nonconformist meeting house

MEDICAL WRITINGS

James Parkinson had an urge to write and as an apprentice he boldly challenged theories of Dr Hugh Smith the younger who had published a book entitled *Philosophy of Physic* and another entitled *Philosophical Inquiries* in 1780 A tract on these books though published anonymously, is attributed to Parkinson

His father was medical assistant to the Royal Humane Society for the New River area, which meant that he was on call for cases of drowning A report of the society for 1778 records that an honorary medal was presented to James " for the recovery of the body of Brian Maxey," on Oct 28 1777

The report of the case which was written by John Parkinson the father states that he and his son were called to a house in Hoxton where a man had hanged himself When they arrived at the house they found him pulseless and to all outward appearances dead but after carrying out the restorative methods recommended by the society—e g., inflation and deflation of the lungs friction, &c —the pulse returned in half an hour natural breathing in forty minutes, and in ninety minutes his senses returned. The patient expressed his sorrow for his horrid crime and the greatest gratitude to those who were instrumental in his restoration to his wife and children."

Parkinson was in good company for Dr Hawes and Dr Cogan instigators of the Royal Humane Society and the illustrious Dr J C Lettsom were medical assistants for the Thames between London Bridge and Westminster Bridge

The society paid two guineas to those attempting resuscitation for two hours, a guinea to the landlord of the public house used as a receiving house and half a crown to the messenger A further two guineas was awarded to the medical assistant if the patient recovered As most of the medical assistants refused payment medals were awarded to them instead. The medal which was silver and had the recipient s name engraved on it was bequeathed in Parkinson s will to his medical son.

Parkinson had had a sound liberal education at a time when most surgeons are said to have been ill-educated He had an extensive practice, and he early showed that he was a keen observer with unusual clinical acumen He wrote many articles for medical journals on cases which he met in his practice as well as those he had been called to see as a medical assistant of the Royal Humane Society

He described the treatment of a child aged 14 months who was found lying face downwards in a tub of water; the attempted resuscitation of a youth who had been drowned and his experiments with an electrical apparatus on the muscles of the limbs the treatment of a servant girl of 28 who was suffering from hydrophobia, and who afterwards died in the London Hospital the treatment of two men who were struck by lightning in a house in Shoreditch both of whom recovered and the recovery of a farm labourer who had been blinded by a flash of lightning while driving cattle in from a field on a stormy night He described a case of trismus, following a compound fracture of the bones of the leg, in which the patient recovered after treatment with heroic doses of tincture of opium and drastic purgation. In a report in 1812 on the post-mortem examination of a boy of 5 he describes a *perforated gangrenous appendix with peritonitis*, believed to be the earliest reference to the disease in English medical literature[3]

He also wrote popular books Today they would have some such titles as ' Home Doctor ' or First Aid for the Sick and Injured. But at the turn of the 18th century they were called *Medical Admonitions for Families* (1799) and the *Villager s Friend and Physic* (1800) A first aid sheet intended to be hung cottager's fireside was called *The Way to H* He wrote a book for children *Dan* which pointed out the dangers of rough games.

Rowntree L. G *Bull Johns Hopk Hosp* 1912 23 33

The first child, James John (born Feb 11 1783) died in infancy the second, John William Keys (born July 11 1785) was apprenticed to his father and became a surgeon the third was Emma Rook (born April [illegible] 1788) the fourth Jane Dale (born Oct 2 1789) died Jan. [illegible] 1792 the fifth Henry Williams was born May 7 1791 and the sixth Mary Dale, was born March 8 1794 James his brother and sister and all his six children, were baptised in St. Leonard s Church.

John William Keys Parkinson married Diana Chapple in St Leonard s Church, on May 7 1811 and they had two children, James Keys (born Oct 29, 1812) and Mary Hester (born March 30 1816) After his wife's death he married again and his wife, Elizabeth Caroline bore him a son, John Ellis (born July [illegible] 18[illegible]0)

Emma Rook Parkinson married John Dymock of Stonehouse Gloucestershire on Oct. 29 1816 at St Leonard s Church, and they had four children The eldest Emma Parkinson Watts Keys Dymock (born November 1821 died Aug 28 1867) married Edward Brown of Croydon The youngest, the Rev Nathaniel Dymock M.A Oxfd, died in 1900, aged [illegible], having been rector of Wymonsfold, Kent and vicar of St Paul s Church Maidstone The other two children died in their teens.

Henry Williams Parkinson married Elizabeth Ascott and left the country to live in Calcutta Mary Dale Parkinson was unmarried at the time of her father's death.

It is probable that descendants of John Watts Keys Parkinson and Emily Rook Dymock are living today

3 Shepherd J A *Lan*

Parkinson suffered from gout, as did his father before him, and in his *Observations on the Nature and Cure of Gout* (1805) he described in detail their symptoms and his own theory as to the origin and pathology of gout But despite the painful enlargements of the interphalangeal joints of his right index finger, he wrote a bold unwavering hand, as may be seen by one of his letters dated 1812, which is in my possession

In his tract, *Hints for the Improvement of Trusses* (1802), which sold for only a few pence, he pointed out the danger of strangulation and how necessary it was for those doing heavy labour to wear a truss A plate was included showing the stages in the construction of the appliance which he had designed for the control of inguinal hernia, which could be constructed by any handy man at a small expense In the preface he deplored the fact that a surgical appliance—a necessity for the preservation of life—could be patented and thus become "a species of monopoly."

Outside his profession he had many interests His *Chemical Pocket Book* (1799) reached five editions His main interest and hobby, however, was geology He had a collecting instinct which grew with the years, and he collected fossils His monumental work on palæontology, *Organic Remains of a Former World* (1804–11), consisted of three large volumes with plates engraved from drawings which he himself had made The cost of these volumes was ten guineas, a large sum in those days, but it must have sold well because there are over twenty copies of it in London libraries alone This work was reprinted twenty six years after his death by his friend, Dr Gideon Mantell, another medical man who became a celebrated geologist

POLITICAL ADVENTURES

Parkinson lived during the French Revolution and the long war with France He was a pacifist and a political reformer, and he wrote many pamphlets under the pseudonym "Old Hubert," in which he advocated the reform of representation of the people in the House of Commons, the institution of annual Parliaments, and universal suffrage He became a prominent member of the London Corresponding Society and the Society for Constitutional Information which had these reforms as their aims

In 1794 the leaders of the societies were arrested and tried for high treason, but were acquitted Parkinson was subpœnaed as a witness at the trial of Thomas Hardy, the founder of the London Corresponding Society, but was not called to give evidence

Shortly before the trials of the leaders, three members of the London Corresponding Society, well known to Parkinson, were arrested and imprisoned without trial, the Government having suspended the Habeas Corpus Act in order to do this They were accused of plotting the assassination of King George III by means of a poisoned dart The deed was to be perpetrated from the pit of the theatre while the King was sitting in his box Parkinson, convinced of the innocence of the accused, wrote to the Privy Council offering to give evidence to prove their innocence The offer was accepted, and in his pamphlet *Assassination of the King* Parkinson set out from memory the questions he was asked and his replies The supposed plot was a frame up, based on false evidence concocted by a Government informer who had been a member of the society, and the prisoners were later freed

The Privy Council were astonished when Parkinson revealed that he was the author of a pamphlet *Revolution without Bloodshed* (1794) His other pamphlets were bitter, sometimes venomous satires, though often mixed with touching pathos One, in particular, was addressed to Edmund Burke In his *Reflections on the French Revolution* Burke referred to the common people as "the swinish multitude" Some 40 tracts were published in reply, including one by Parkinson, *An address to the Hon Edmund Burke from the Swinish Multitude* (1[illegible] in which he wrote

"As to yourself, good sir, there are those who c resemble the venomous asp, whose poison is placed its tongue, or the Camelon, and like that creature, appearance ever changes with your situation"

SOCIAL REFORMS

The wretchedness of the labouring poor, the and misery of their homes in Hoxton and had made Parkinson an ardent social reformer He had an unfortunate experience

He was called to see a widow named Mary D Rosoman Street, Clerkenwell, who had been wandering the street at night, had heard voices coming down the accusing her of having killed her husband, and who concealed a knife in her dress, presumably with suicidal Parkinson saw her after she had been admitted to a asylum As a result of his examination he did not think she was certifiable, so he made inquiries in neigh houses, questioned her nephew and niece Mr and Benjamin Elliott, her lodger, and her son aged 16, who he was convinced that his mother was insane returned to the mad house, and, as a result of a examination, signed the certificate for her detention.

After a few weeks she was sitting looking out of the when she saw a woman friend, to whom she shouted that was being detained against her will The friend inf brother, and other friends, who secured her release years later, Benjamin Elliott was tried at the C sessions house, on an indictment charging him, his wife, Sarah Bodkin, with conspiring to deprive Mary D of her liberty He was found guilty and sentenced months' imprisonment

A storm of criticism of Parkinson's conduct appeared daily press He was accused of certifying Mary Daintree as the result of his own observations, but on info supplied by others Fellows of the Royal College of Phys who were visitors in lunacy, expressed surprise that he not "contradicted the calumnies raised against him" son, now aged 19, in the witness box denied that Par had ever questioned him, and Parkinson did not recognise though he did afterwards, when it was too late

In a tract, entitled *Mad-houses Observations on Act regulating mad houses* (1811) he vindicated h and suggested that two medical certificates ought to required, instead of one, and that the aid and di of a justice of the peace was necessary

In 1819 Parkinson published a tract *Observations necessity for Parochial Fever Wards* He related h an epidemic of fever among the inhabitants of one of numerous courts off the Kingsland Road, Shoreditch, could not obtain the services of hired nurses and bours shunned them He suggested that parochial wards should be established, containing 18 beds (6 men, and 12 for women) for a population of say persons When the epidemic was over the building be used as an infirmary Parkinson was visiting p to the parish infirmary in the Kingsland Road, which built in 1777, and St Leonard's Hospital now stan the site He deplored the fact that there was only hospital for pauper fever patients in London, and th 70 beds were inadequate It was over fifty years an Act forced local authorities to provide iso accommodation for fever cases

Fully occupied as he must have been with his m practice, and despite his devotion of his leisure h his favourite science, he found time to interest in the affairs of the parish of St Leonard In 1 was elected by his fellow-parishioners a trustee for liberty of Hoxton, and he remained a member of the until he died

The committee which managed the Sunday school at St Leonard's Church, appointed him as secretary 1807, Mr Samuel Whitbread, M P, the brewer, b Bill before the House of Commons to establish in every parish throughout the country, for the of poor children, whereby each child should have opportunity of attending school for two years at expense of the State Parkinson wrote a tract *C* ns on *Mr Whitbread's Plan for the Education of the bor* (1807), in which he said that a debt of gratitude was e to the proposer of the Bill, but he feared that as a sult of the establishment of these parochial day schools e Sunday schools would suffer He maintained "that mere literary education without the inculcation of oral and religious principles would prove highly *jurious.*" *Furthermore* the parents whose children rned one to three shillings per week up to the age of 14 d five shillings per week after this age, were unlikely to rego this money for the sake of the children s education. Much concerned with the welfare of the children of the unday school, he kept a register containing the names all children who were seeking employment, with rticulars concerning their abilities, behaviour &c., hich was open to inspection by prospective employers, cause he felt that the welfare of poor children was eatly influenced by their first situations in employment He was also concerned for the welfare of pauper ildren of the parish who were apprenticed to masters d mistresses not in their own parish, but in neigh uring parishes, lest they should become chargeable in ult life He reflected that no law existed by which the ities of the employer were defined, nor were any spectors appointed to visit the children to see the nditions under which they worked. He succeeded in rsuading the vestry to appoint some of the trustees voluntary visitors. Later, visitation by paid inspectors as laid down by Act of Parliament.

About this time Malthus maintained that the earth ould not be able to yield enough food to feed the pidly increasing population Parkinson thought other se and said that if the population exceeded the means support the fault lay not in nature but in the ability politicians to discover some latent defect in the laws specting the division and appropriation of property'

PARKINSON'S DISEASE

In 1817 he wrote the *Essay on the Shaking Palsy* hich has brought him posthumous fame in the medical orld His description of the disease which now bears s name has never been bettered, though it has been panded He considered the cause to be principally n the medulla spinalis of the cervical region its mem anes, or the containing theca' and he hoped that some ctor would one day have the opportunity of examining e body of a patient who had died from the disease— r he modestly apologised for the hypothetical nature his observations on its pathology The following tract from the essay is an example of his pleasing erary style

> "The patient experiences much inconvenience, which *happily is found daily to increase* The submission of the mbs to the direction of the will can hardly ever be obtained in e performance of the most ordinary offices of life The gers cannot be disposed of in the proposed directions, and plied with certainty to any proposed point. As time and e disease proceed difficulties increase writing can now be rdly at all accomplished and reading from the tremulous ption, is accomplished with some difficulty Whilst at meals e fork, not being duly directed, frequently fails to raise the orsel from the plate which when seized is with much fficulty conveyed to the mouth. At this period the patient ldom experiences a suspension of the agitation of the limbs. mmencing for instance in one arm, the wearisome agitation borne until beyond sufferance, when, by suddenly changing e posture it is for a time stopped in that limb to commence nerally in less than a minute in one of the legs, or in the n of the other side Harassed by this tormenting round patient has *recourse to walking a mode of exercise* to hich the sufferers from this malady are in general partial; ing to their attention being thereby somewhat diverted m their unpleasant feelings, by the care and exertion uired to ensure its safe performance'

LAST YEARS

It has been said that Parkinson received no honour recognising the disease as a clinical entity, nor for his work on palæontology True he was given no honorary degree nor was he elected to the fellowship of the Royal Society, but he did receive recognition from the Royal College of Surgeons of England, whose honorary gold medal was awarded him in 1822 He was indeed, the first to receive this award (instituted twenty years before) and it has been bestowed only fifteen times in the past hundred and fifty years, the recipients including Lord Lister Sir James Paget and Richard Owen

It seems clear, too that Parkinson was held in high esteem by his fellow general practitioners, for in 1818 he was chairman of the Association of Apothecaries and Surgeon Apothecaries of England and Wales He was also a member of many learned medical and geological societies He was one of eleven people who met at the Freemason's Tavern, Great Queen Street, in 1807, and founded the Geological Society of London, and he was on the council from 1813 to 1815 He was a member of the Wernerian Society of Edinburgh and the Cæsarean Society of Moscow He was a fellow of the Medical Society of London, and a member of the London Medical and Chirurgical Society

Parkinson is believed to have retired when he exchanged houses with his son, who continued the family practice in Hoxton Square He died on Dec. 21, 1824 at no 3, Pleasant Row, Hoxton and an entry in the burials register of St Leonard's Church reads: 'No 741 James Parkinson, Kingsland Road buried December 29th 1824 R Crosby" His remains were interred in the graveyard attached to the church, but no tombstone can now be found

No portrait of Parkinson is known to exist, and the only description we have of him is by his friend Mantell who wrote 'Mr Parkinson was rather below middle stature with an energetic intelligent, and pleasing expression of countenance, and of mild and courteous manners readily imparting information either on his favourite science or on professional subjects"

Parkinson was truly a general medical practitioner; and his impact on his own generation and his influence on succeeding generations is shown by the number of his ideas, both social and scientific, that are now generally accepted.

My thanks are due to Dr W McMenemey Dr J Dymock, and Mr Jackson borough librarian at Shoreditch for their assistance in obtaining biographical details

Points of View

HOLES, KNOBS, AND WIRES

Abstract Art and Auto-suggestion

Sir Henry Turner, C.B.E.

The public is in these days learning in some degree to tolerate persons who act abnormally We try to persuade ourselves that they are sometimes, in effect being pushed from behind and not just "bloody minded' And I think that we ought to use this charitable approach in considering why artists—many of them possessing unquestionably skilful technique—produce what are at *first sight* (and often later) meaningless doodles lumps of stone pierced by quite unsuggestive holes, tangles of wire and so forth

So, with a layman s proper timidity I shall attempt an answer to the questions—'Why is abstract art produced, and why is it taken seriously by people seemingly well qualified to appraise it?'

* * *

In the first place I would suggest this experiment Take three (or more) upholsterer s coiled springs, entangle them and mount the result in an inverted aquarium bowl indirectly lit with a professionally lettered card reading (for example) *Time Passing* This should be exhibited in a place of some importance Failing the Tate, *a Bond street art-dealer's window will do*

The reactions of observers will fall into four categories

(a) Confident, extravert derision

(b) Open disconcertment "I suppose I ought to see something in it"

(c) Insincere praise, to dodge a charge of artistic insensitivity

(d) Prolonged study, and a true statement of pleasure in a new æsthetic experience

There is no reason to trouble about (a) They are happy enough, even though scorned by the others But something can, I think, be done about the uncomfortable inferiority feeling of (b), and the unpleasant, self damaging deceitfulness of (c) The remedy seems to lie in an understanding of the auto hypnotic process employed by class (d), who are the prime instigators of the confusion

The proposition which I would like considered by better qualified readers is that the key to understanding both the origin and the appreciation of abstract art lies in the mechanism of auto hypnosis By this mechanism the observer persuades himself that the object possesses in itself a quality affording æsthetic pleasure

In the experiment I have recommended, all the apparatus is present for producing, first, a light hypnoidal state, and, second, a post hypnotic effect There is the steady gaze, the illumination casting surrounding objects into relative gloom, respect, tinged perhaps with awe, for the creator of the intriguing Thing, a pretty strong initial conviction that the Thing has profound significance, and not merely a hope, but an expectation of satisfaction through artistic achievement The effect of all this, upon a hypnotically susceptible person, is to turn on, so to speak, the switch marked Æsthetic Thrill

From this it seems to follow that literally *any* object can be used as an emotional trigger by class (d), supposing the right circumstances They self-induce emotion, and then use that emotion as proof that something tangible exists as its rational cause The people who can perform this pleasurable mental antic could equally well, presumably, produce religious exaltation, quickened body-healing power, and all the other phenomena which result from successful auto- (or hetero-) suggestion It would be interesting to know whether all those who can achieve admiration for abstract art are in fact "good" subjects for post-hypnotic suggestion in general

My hypothesis gains some corroboration from the fact that the phases of successive cults of purely abstract art are briefer than those depending on more direct appeal—i e, the straight, representational, associative styles The relatively short lives of Dadaism and Cubism may be due to their dependence on auto hypnosis Hypnotic suggestions do, I believe, tend to wear out, they wear out too soon for them to be widely transmitted, by training, from one generation to another Surrealism seems to be lasting better, because it uses recognisable objects which, although irrationally juxtaposed, do provide some ordinary associative prompting

While I have provided (to my own satisfaction) a rational explanation of artistic admiration of meaningless objects, I have not dealt with the abstract artist himself But I suggest that my theory covers him too All creative artists (I think it is agreed) achieve abnormally close contact with their unconscious mental mechanism y induce this by the age old processes of muscular ition, immobility, and disregard of environment, ometimes by means of alcohol or drugs They are e who seek, with profound and reckless desire, gher allegiance and transcendence of personal ity, and they seem to have something in common the Buddhist and other contemplative religious s, perhaps even the Christian Scientists, whose tings are almost totally without meaning to those sceptible to suggestion

* * *

So my conclusion is that no one need be by his incompetence in sharing the enthusiasm of of abstract art, of jazz music, or "stream of ness" prose Nor indeed, of those people who fishing float to induce a light trance state for from their horrid homes These are all ways of from more or less distressing reality We are the ones if we have no need for such refuges.

Public Health

COWPOX IN MAN

And its Relationship with Milker's Nodule

BERNARD LAURANCE
M B Lond, M R C P, D C H

*CONSULTANT PÆDIATRICIAN, DERBY CITY HOSPITAL
DERBYSHIRE HOSPITAL FOR SICK CHILDREN, LATELY
REGISTRAR, BRISTOL ROYAL HOSPITAL FOR SICK*

PROPHYLACTIC inoculation against smallpox with fluid from a vesicle or pustule of a patient the disease is known to have been practised for centuries in various parts of the world In ancient dried crusts from a smallpox pustule were inserted the nostril on "a lucky day"—a practice known "sowing the smallpox" This is a fine example of successful empiricism of some ancient Chinese for we now know that variola virus can survive for a year in dried crusts and floor dust (Downie and D 1947)

Variolation was introduced into England at the of the 17th century Before then many travellers brought back news of this form of inoculation, Dr Martin Lister was probably the first to cc the method to the medical profession in this In 1695 he published a tract on smallpox that in correspondence between the secretary of the R Society and many physicians from abroad possibly led to the famous letter written in 1713, read by Dr John Woodward to the society in 1714 which Dr Timoni of Constantinople advocated the duction of inoculation into Great Britain (Stearns There is some evidence that the method was before this time in South Wales (Shrewsbury 1951)

For the adoption of the practice in this Lady Mary Wortley Montagu, the wife of the Ambassador to the Ottoman Court, was responsible She was impressed by the methods she seen practised in Turkey to lessen the dreaded of smallpox, and wrote to her friends in England of experiences The following is an extract from a written in 1717

> "Apropos of distempers, I am going to tell you a that I am sure will make you wish yourself here The so fatal, and so general amongst us, is here entirely by the invention of *ingrafting*, which is the term they give There is a set of old women who make it their business perform the operation every autumn, in the month of ember, when the great heat is abated People send to another to know if any of their family has a mind to have smallpox, they make parties for this purpose, and when are met (commonly fifteen or sixteen together), the woman comes with a nutshell full of the matter of the sort of smallpox, and asks what veins you please to opened She immediately rips open that you offer to her a large needle (which gives you no more pain than a scratch) and puts into the vein as much venom as can upon the head of her needle, and after binds up the little with a hollow bit of shell, and in this manner opens f five veins The French Ambassador says pleasantly, they take the smallpox here by way of diversion, as they the waters in other countries"

By 1721 Lady Mary had returned to England largely by persuading the Princess of Wales to have children inoculated against smallpox in the Tu er established the method in this country entually fell into disrepute because of the s which occasionally resulted and also use of the severity of the inoculated disease quently in 1840 it was declared illegal

ny different persons have been said to have vered the value of inoculation with cowpox rophylaxis against smallpox In the minutes meeting of the Vaccine Pock Institution in 1805 there is a note that Benjamin Jesty noculated his wife and children with cowpox '74 (personal communication to Prof A V o from Mr E Jesty a descendant of Ben n) The fact remains that it was Edward er who recognised that cowpox could be smitted artificially from one person to another foresaw its prophylactic value

nner had observed that horses were subject disease characterised by an eruptive condi of the pasterns and known to farriers of that as the grease ' Nowadays "the grease ' s specifically to a chronic dermatitis of the legs, seen icularly in cart horses working on heavy land whose ming is neglected, but in Jenner's time the term rred to an inflammatory swelling of the heel pre ably including vesicular lesions, from which issued atter of a very peculiar kind ' : usually the disease d be transmitted via cows to man

nner considered that this disease resembled small He noticed that if a man dressed a horse suffering a "the grease ' and then milked cows, the teats of the s developed pustules and the infection was some es transmitted to dairymaids—who subsequently ame immune from smallpox (This immunity had bably been suspected earlier by others the nursery me Where are you going to, my pretty maid ? example, doubtless refers to the dairymaid's pox complexion) Consequently on May 14 1796 Jenner ulated a boy James Phipps with matter from a ical cowpox lesion on a dairymaid's finger, sub uent inoculation of this boy with matter from a allpox lesion was unsuccessful

ater Jenner realised that if ' the grease ' was trans ted to human beings direct from horses without sing through the cow phase, these patients would still immune to cowpox; indeed, cowpox and horsepox he grease) are now known to be the same disease gan and Bruner 1951) or closely related. In 1798 published his work resulting from this initial experi nt in a book entitled *An Inquiry into the Causes and ects of the Variolæ Vaccinæ a disease discovered in e of the Western Counties of England particularly oucestershire and known by the name of the Cow x*

It is appropriate that the following description of a all outbreak of cowpox should come from a part of oucestershire only seventeen miles from Berkeley nner's home in Gloucestershire

Clinical Account

The outbreak took place on a small farm some five miles m Bristol. A herd of eighteen cows, to which there had been no recent addition was kept About Dec. 1 1953 the farmer noticed that some of the herd were generally upset and irritable and that at milking time they kicked more than usual. Their yield of milk diminished for about ten days and hand milking which was practised became even more difficult when the teats swelled and vesicles appeared on their surface (fig 1) These vesicles later ulcerated (fig 2) producing an obnoxious smell that only a Gloucestershire farmer's colourful dialect could describe In his second book—*Further observations on Variolæ Vaccinæ* (1799)—Jenner mentions a doctor friend's report that the cows ' gave off an offensive stench from their udders, though he considered this odour unusual among cows affected by cowpox

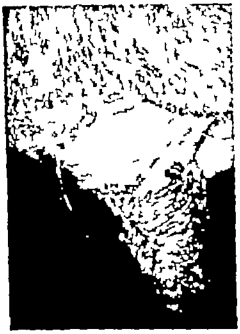

Fig. 1—Vesicles on cow's teat.

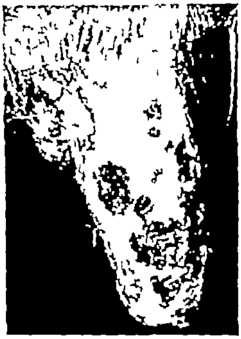

Fig. 2—Ulcers on cow's teat.

On Dec 3 the farmer aged 32 and never vaccinated previously noticed a pimple on the dorsum of his right thumb subsequently it became a vesicle and scabbed over one week later (fig 3) During this week a pimple also appeared on the right index finger but rapidly disappeared At the same time there was headache lassitude fever and lymphangitis with axillary and epitrochlear lymphadenitis of the right arm. He had to work throughout this illness, and on Dec 19 he felt worse and the scab on the thumb was larger (fig 4) Two days later the scab separated together with some pus which had probably formed as the result of secondary infection. He then recovered and the thumb healed leaving a small scar

The only other persons living on the farm were the farmer's wife his daughter and a cowman all of whom had been vaccinated in infancy and were unaffected by the cowpox No other outbreak was reported in either cows or man in the neighbourhood

Virology

Dr J A Dudgeon of St. George's Hospital Medical School kindly investigated serum from the farmer which was taken on the ninth and eighteenth days of the disease Unfortunately no vesicle fluid could be obtained for the lesion had scabbed over by the time it was first seen There was a distinct rise in complement fixing antibody to the viruses of both vaccinia and cowpox

Specimen of serum	*Cowpox virus*	*Vaccinia virus*
9th day of disease	1 : 10	1 : 5
18th day of disease	1 : 160	1 : 320

These viruses are generally held in this country to be distinct though closely related the virus of vaccinia being a laboratory strain the precise origin of which is not clear

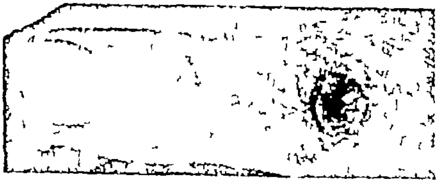

Fig 4—Farmer's thumb about fifteen days after appearance of vesicle

lettered card reading (for example) *Time Passing* This should be exhibited in a place of some importance Failing the Tate, a Bond street art dealer's window will do

The reactions of observers will fall into four categories

(*a*) Confident, extravert derision

(*b*) Open disconcertment "I suppose I ought to see something in it"

(*c*) Insincere praise, to dodge a charge of artistic insensitivity

(*d*) Prolonged study, and a true statement of pleasure in a new æsthetic experience

There is no reason to trouble about (*a*) They are happy enough, even though scorned by the others But something can, I think, be done about the uncomfortable inferiority feeling of (*b*), and the unpleasant, self-damaging deceitfulness of (*c*) The remedy seems to lie in an understanding of the auto hypnotic process employed by class (*d*), who are the prime instigators of the confusion

The proposition which I would like considered by better qualified readers is that the key to understanding both the origin and the appreciation of abstract art lies in the mechanism of auto-hypnosis By this mechanism the observer persuades himself that the object possesses in itself a quality affording æsthetic pleasure

In the experiment I have recommended, all the apparatus is present for producing, first, a light hypnoidal state, and, second, a post hypnotic effect There is the steady gaze, the illumination casting surrounding objects into relative gloom, respect, tinged perhaps with awe, for the creator of the intriguing Thing, a pretty strong initial conviction that the Thing has profound significance, and not merely a hope, but an expectation of satisfaction through artistic achievement The effect of all this, upon a hypnotically susceptible person, is to turn on, so to speak, the switch marked Æsthetic Thrill

From this it seems to follow that literally *any* object can be used as an emotional trigger by class (*d*), supposing the right circumstances They self induce emotion, and then use that emotion as proof that something tangible exists as its rational cause The people who can perform this pleasurable mental antic could equally well, presumably, produce religious exaltation, quickened body-healing power, and all the other phenomena which result from successful auto- (or hetero-) suggestion It would be interesting to know whether all those who can achieve admiration for abstract art are in fact "good" subjects for post hypnotic suggestion in general

My hypothesis gains some corroboration from the fact that the phases of successive cults of purely abstract art are briefer than those depending on more direct appeal—i e, the straight, representational, associative styles The relatively short lives of Dadaism and Cubism may be due to their dependence on auto hypnosis Hypnotic suggestions do, I believe, tend to wear out, they wear out too soon for them to be widely transmitted, by training, from one generation to another Surrealism seems to be lasting better, because it uses recognisable objects which, although irrationally juxtaposed, do provide some ordinary associative prompting

While I have provided (to my own satisfaction) a rational explanation of artistic admiration of meaningless objects, I have not dealt with the abstract artist himself But I suggest that my theory covers him too All creative artists (I think it is agreed) achieve abnormally close contact with their unconscious mental mechanism They induce this by the age old processes of muscular relaxation, immobility, and disregard of environment, and sometimes by means of alcohol or drugs They are people who seek, with profound and reckless desire, a higher allegiance and transcendence of personal identity, and they seem to have something in common with the Buddhist and other contemplative religious s, perhaps even the Christian Scientists, whose s are almost totally without meaning to those ptible to suggestion

* * *

So my conclusion is that no one need be by his incompetence in sharing the enthusiasm of of abstract art, of jazz music, or "stream of ness" prose Nor indeed, of those people who u fishing-float to induce a light trance state for from their horrid homes These are all ways of from more or less distressing reality We are the ones if we have no need for such refuges.

Public Health

COWPOX IN MAN

And its Relationship with Milker's Nodules

BERNARD LAURANCE
M.B Lond, M.R C P, D C.H

CONSULTANT PÆDIATRICIAN, DERBY CITY HOSPITAL A DERBYSHIRE HOSPITAL FOR SICK CHILDREN, LATELY SEN REGISTRAR, BRISTOL ROYAL HOSPITAL FOR SICK CHILD

PROPHYLACTIC inoculation against smallpox (vari with fluid from a vesicle or pustule of a patient wi the disease is known to have been practised for ma centuries in various parts of the world In ancient Ch dried crusts from a smallpox pustule were inserted in the nostril on "a lucky day"—a practice known "sowing the smallpox" This is a fine example of th successful empiricism of some ancient Chinese medici for we now know that variola virus can survive for ov a year in dried crusts and floor dust (Downie and Dumb 1947)

Variolation was introduced into England at the e of the 17th century Before then many travellers h brought back news of this form of inoculation, b Dr Martin Lister was probably the first to communic the method to the medical profession in this count In 1695 he published a tract on smallpox that result in correspondence between the secretary of the Roy Society and many physicians from abroad Th possibly led to the famous letter written in 1713, a read by Dr John Woodward to the society in 1714, which Dr Timoni of Constantinople advocated the intr duction of inoculation into Great Britain (Stearns 195 There is some evidence that the method was pract before this time in South Wales (Shrewsbury 1951)

For the adoption of the practice in this count Lady Mary Wortley Montagu, the wife of the Brit Ambassador to the Ottoman Court, was chief responsible She was impressed by the methods she h seen practised in Turkey to lessen the dreaded p of smallpox, and wrote to her friends in England of h experiences The following is an extract from a lett written in 1717

> "Apropos of distempers, I am going to tell you a th that I am sure will make you wish yourself here The smallp so fatal, and so general amongst us, is here entirely harm by the invention of *ingrafting*, which is the term they give There is a set of old women who make it their business perform the operation every autumn, in the month of Se ember, when the great heat is abated People send to o another to know if any of their family has a mind to have smallpox, they make parties for this purpose, and when th are met (commonly fifteen or sixteen together), the woman comes with a nutshell full of the matter of the b sort of smallpox, and asks what veins you please to b opened She immediately rips open that you offer to her a large needle (which gives you no more pain than a com scratch) and puts into the vein as much venom as can upon the head of her needle, and after binds up the little wo with a hollow bit of shell, and in this manner opens four five veins The French Ambassador says pleasantly, they take the smallpox here by way of diversion, as they the waters in other countries"

By 1721 Lady Mary had returned to England largely by persuading the Princess of Wales to have children inoculated against smallpox in the Turk nner established the method in this country eventually fell into disrepute because of the ths which occasionally resulted, and also ause of the severity of the inoculated disease sequently in 1840 it was declared illegal

lany different persons have been said to have covered the value of inoculation with cowpox prophylaxis against smallpox In the minutes a meeting of the Vaccine Pock Institution d in 1805 there is a note that Benjamin Jesty l inoculated his wife and children with cowpox 1774 (personal communication to Prof A V ale from Mr E Jesty a descendant of Ben nin) The fact remains that it was Edward nner who recognised that cowpox could be nsmitted artificially from one person to another d foresaw its prophylactic value

Jenner had observed that horses were subject a disease characterised by an eruptive condi on of the pasterns and known to farriers of that ne as the grease" Nowadays 'the grease ers specifically to a chronic dermatitis of the legs, seen rticularly in cart horses working on heavy land whose ooming is neglected, but in Jenner's time the term ferred to an inflammatory swelling of the heel, pre mably including vesicular lesions from which issued matter of a very peculiar kind usually the disease uld be transmitted via cows to man

Jenner considered that this disease resembled small x He noticed that if a man dressed a horse suffering om ' the grease" and then milked cows, the teats of the ws developed pustules; and the infection was some mes transmitted to dairymaids—who subsequently came immune from smallpox (This immunity had obably been suspected earlier by others the nursery yme Where are you going to, my pretty maid?' r example doubtless refers to the dairymaid's pox e complexion) Consequently on May 14 1796 Jenner oculated a boy James Phipps, with matter from a pical cowpox lesion on a dairymaid's finger sub quent inoculation of this boy with matter from a nallpox lesion was unsuccessful

Later Jenner realised that if ' the grease" was trans tted to human beings direct from horses, without ssing through the cow phase, these patients would still immune to cowpox indeed, cowpox and horsepox the grease) are now known to be the same disease lagan and Bruner 1951) or closely related In 1798 published his work resulting from this initial experi ent in a book entitled *An Inquiry into the Causes and ffects of the Variolæ Vaccinæ, a disease discovered in me of the Western Counties of England, particularly* loucestershire *and known by the name of the Cow* ox

It is appropriate that the following description of a nall outbreak of cowpox should come from a part of loucestershire only seventeen miles from Berkeley enner's home in Gloucestershire

Clinical Account

The outbreak took place on a small farm some five miles om Bristol A herd of eighteen cows to which there had been no recent addition, was kept About Dec. 1 1953 the farmer noticed that some of the herd were generally upset and irritable and that at milking time they kicked more than usual. Their yield of milk diminished for about ten days and hand milking which was practised became even more difficult when the teats swelled and vesicles appeared on their surface (fig 1) These vesicles later ulcerated (fig 2) producing an obnoxious smell that only a Gloucestershire farmer's colourful dialect could describe. In his second book—*Further observations on Variolæ Vaccinæ* (1799)—Jenner mentions a doctor friend's report that the cows gave off an offensive stench from their udders, though he considered this odour unusual among cows affected by cowpox.

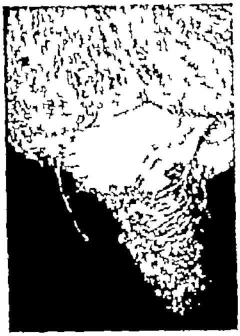

Fig. 1—Vesicles on cow's teat.

Discussion

Recent medical literature includes few references to cowpox in man Possibly the disease is thought not worth recording, particularly in view of adequate earlier accounts, certainly it became less common after the introduction of vaccination, but with the declining popularity of vaccination it may be seen more often According to local veterinary practitioners the disease is still fairly common among cows in the West Country, but is rare in horses

Most veterinary authorities distinguish vaccinia of cows from cowpox of cows Cow vaccinia originates in man, whereas cowpox is a specific disease of cows, independent of infection from human sources, though giving rise to cowpox in man (Davies et al 1938) Nomland and McKee (1952), however, consider that genuine cowpox in cows arises from contact with recently vaccinated persons Cows are usually ill, and their yield of milk decreases, when they have cowpox, they recover in a few weeks When human beings contract the disease from cows, they develop headache, malaise, and fever, and lesions typical of vaccinia appear

Such a description accords well with the outbreak reported here, though no recently vaccinated person is known to have been in contact with the cows for a considerable time before the outbreak The rise of antibody titres to both cowpox and vaccinia confirms the diagnosis of cowpox in the farmer

Cowpox in man needs to be distinguished from "milkers' nodules"

Bonnevie (1937) gives an account of "milkers' nodules," which he terms "milkers' warts," ascribing this disorder to a virus allied to that of vaccinia Characteristically, nodular lesions appear on the teats of the cattle, but do not upset them constitutionally The nodules give rise to painless, bluish red, indolent nodes on the hands, arms, and face of milkers Usually there are no constitutional symptoms, though axillary adenitis is sometimes present The incubation period is eight to ten days, and the lesions heal after six to ten weeks, without scarring, unless there has been secondary infection Vaccination against smallpox does not prevent the nodules from appearing (Davies et al 1938, Danbolt 1949, Nomland and McKee 1952)

Clinically, genuine cowpox or vaccinia is easily distinguished from false cowpox or milkers' nodules. The cowpox virus was identified many years ago, but that of milkers' nodules has eluded many investigators The evidence seems to point to its being allied to, but distinct from, the cowpox virus, the infection has often been termed paravaccinia of Lipschutz (Morozov 1940, Becker 1940) Lately, Findlay and Haig (1952) claim to have isolated the virus

In Jenner's original monograph the two conditions were clearly distinguished, for he wrote

> "It is necessary to observe that pustulous sores frequently appear spontaneously on the nipples of Cows, and instances have occurred, though very rarely, of the hands of servants employed in milking being affected with sores in consequence, and even of their feeling an indisposition from absorption
>
> "These pustules are of a much milder nature than those which arise from that contagion which constitutes the true Cow Pox They are always free from the bluish or livid tint so conspicuous in the pustules in that disease No erysipelas attends them, nor do they shew any phagedenic disposition as in the other case, but quickly terminate in a scab without creating any apparent disorder in the cow This complaint appears at various seasons of the year, but most commonly in the Spring, when the Cows are first taken from their winter food and fed with grass It is very apt to appear also when they are suckling their young
>
> "But this disease is not to be considered as similar in any respect to that of which I am treating (i e, cowpox), as it is incapable of producing any specific effects on the human constitution
>
> "However, it is of the greatest consequence to point it ore, lest the want of discrimination should occasion an idea of security from the infection of the smallpox, might prove delusive"

I wish to thank Dr E P K. Rushton, of P Gloucestershire, for informing me about the farmer in instance Prof F Blakemore, of the University of B kindly gave me help on the veterinary aspects of this The photographs were taken by the department of photography, University of Bristol

Medicine and the Law

The Overturned Inhaler

A 9-year old girl was under treatment in a childre hospital following poliomyelitis, she could not move legs, had to be propped up to sit, and had only a limi use of fingers and arms When she developed s bronchial trouble, the nursing staff, after various exp ments, devised a method of enabling her to use an inha herself they propped her up in bed, put a pillow her lap, and placed the padded inhaler bottle in a d tray on the pillow The child was then able to put hands round the inhaler and reach the spout At f she did it with someone standing over her, but later managed it herself while the nurse in the ward went with other duties This worked successfully for months

At 6 30 one morning the night nurse, who had sixt children and two wards to attend to, woke the child gave her the inhaler in the usual way The nurse then to go to the sluice about ten paces down the corri While she was out of the ward, she heard cries and c back to find that the inhaler had somehow been ti over and its scalding contents had soaked throug the child's legs and thighs, causing second-degree bu The child by her mother brought an action for neglige against the group hospital management committ Mr Justice McNair held that neither the nurse nor administration had been negligent The plaintiff appeal

In the Court of Appeal on March 28 Lord Jus Denning said that the court agreed with the judge t the positioning of the child and the inhaler were best that could be devised, and that the defendants w not negligent on that point The more difficult quest was whether this little girl, helpless as she was, ought have been left alone at all while using an inhaler c taining boiling water To answer it the court had consider the situation both of the nurse and of the hosp system

The nurse was dealing with the other little g She had to be near at hand in case of difficulty, and had been near at hand all the time in the very wa except for the few moments or seconds when she went the sluice Was that negligence on her part to leave room for that very short while? It might have be negligence in the early stages before it had been se that the little girl could manage the inhaler But t judge was right in holding that, after she had managed quite well for two months, it could not be negligence the part of the nurse, who had all these children un her care, to leave the ward for that very short time

---

[1] See *Lancet*, 1954 ii, 1332

Vas the administration then to blame for not having anged for the inhalations to be done at a time when the se was not so rushed, or for not telling her that if she s called out of the room she should put the tray le? The court could not consider those matters, for y had not been investigated before the judge One l to be careful in these cases not to be wise after the nt. Hospitals and nurses had the whole round of ly duties to attend to, and, with all the skill and care at could reasonably be expected of them, misadventures l occur This was such a misadventure, as the judge d found, though it was one which might perhaps help prevent others in future

Lord Justice Parker and Mr Justice Roxburgh agreed d the appeal was dismissed.

Alleged Libel by Doctor

A man sued a limited company for damages for rsonal injuries sustained in a road accident, and the mpany's solicitors instructed a doctor to examine him fter doing so, the doctor made a report to the solicitors ho quoted part of it in a letter to the patient's solicitors s follows:

> I then asked him what he would do if I recommended im to go back to work at once; he replied that he would o but that he would need three secretaries a chauffeur and ndry other bodies to do the work he formerly carried out ingle-handed because he would be unable to do the work imself I then asked him how long he thought it would be efore he recovered and he stated that he could wait 50 or 60 ears if necessary
>
> His demeanour during this interview was almost a cari ature—lying in bed smoking a cigar in his private single oom the picture of comfort with his radio and photographs. e was cocksure arrogant and self-opinionated

The patient saw this letter and started proceedings gainst the doctor for damages for alleged libel. The octor in his defence claimed inter alia that the eport was privileged The plaintiff in reply alleged nalice.

Mr Justice Donovan on an application by the laintiff refused to make an order that the plaintiff hould be allowed to see and inspect the whole of the eport and other documents passing between the doctor nd the company's solicitors The plaintiff appealed

In the Court of Appeal on March 30 Lord Justice ingleton (dissenting) said that the purpose of this ranch of the law of privilege was to enable a litigant r a party to impending litigation to prepare his case Statements had to be taken and reports obtained rima facie, they were the subject matter of privilege The privilege was that of the litigant but it inured for he benefit of the one who had made the report. A tatement so given should, generally speaking be egarded for this purpose in the same light as if it were iven in court To make an order of the kind suggested vould be a departure from the recognised practice and vould have the effect of deterring potential witnesses rom giving statements to solicitors whose clients vere concerned in litigation He would dismiss the ppeal

Lord Justice Hodson said that the claim to privilege vas based on legal professional privilege The rivilege was that of the litigant and not of his witnesses s such. For the purposes of this application, the doctor nust be looked at as a proposed witness on behalf of the ompany In that capacity not only had he no privilege f his own but he was under no duty to assert the right f the company He his Lordship would allow the ppeal subject to the concession by the plaintiff that he order for inspection was to take effect only when the ction against the company for personal injuries was isposed of

Lord Justice Romer agreed that the appeal should be llowed Leave to appeal to the House of Lords was ranted

Negligence Claim Dismissed

In an action in which an orthopædic surgeon claimed a fee of £48 6s for treating a woman patient's broken ankle judgment and costs were given to the surgeon A counter-claim by the patient for damages for alleged negligence was dismissed [1]

The patient by profession a teacher of dancing, alleged that a month after setting her ankle in plaster the surgeon had forced her to walk upon it in his surgery he had removed the plaster and manipulated her foot, causing her great pain The surgeon said in evidence that the fracture had been a severe one, and permanent disability would have resulted whatever the treatment. He had heard nothing of the allegations against him until five years after the injury

Giving judgment the judge said that he was unable to accept the patient's story He was satisfied that there had been nothing in the surgeon's conduct with which he should reproach himself

Injury to Hæmophiliac

How far should a person be liable for the consequences of his own negligence? Should he be liable only for what might be called the "normal" consequences or should his liability extend further? A hæmophiliac, who suffered injuries which to a normal person would have been comparatively trivial, has been awarded £3000 agreed damages and costs in the High Court [2]

The plaintiff a 35 year-old man said that he had suffered all his life from hæmophilia and had been in hospital over two hundred times. While driving his van in the Old Kent Road London, in July 1953 he was involved in a collision with an ambulance belonging to the London County Council. The accident caused bleeding into the hip and knee joints and made him a good deal worse than before Judgment was entered against the London County Council and the ambulance driver

The cases on remoteness of damage are not easy to reconcile but it seems clear that, where negligence is established the defendant is liable for all the direct physical consequences of his unlawful act Liability is therefore not limited in such cases to the normal consequences The award of £3000 damages in the present case appears to be in line with that principle

Parliament

Transfer of Functions of the Ministry of Food

IN the House of Commons on March 28 Mr HARRY CROOKSHANK, Lord Privy Seal, explained that it was now proposed by order to merge the Ministry of Agriculture and Fisheries and the Ministry of Food The interest of the Ministry in the food and drugs legislation would in a subsequent order be allocated to the Minister of Health, who would have the primary responsibility for hygiene problems. The new Minister of Agriculture Fisheries and Food would deal with the regulations about the composition of food to safeguard health and to prevent fraud and the regulations about food labelling

Mr ARTHUR BLENKINSOP was uneasy that matters dealing with the composition of food to safeguard health should not go to the Ministry of Health He asked for a better explanation of the Government's intentions. Mr HEATHCOAT AMORY Minister of Agriculture and Fisheries and Minister of Food assured the House that the second order would be brought forward as soon as possible The intention was that the primary responsibility for cleanliness and hygiene should go to the Ministry of Health with one exception The primary responsibility for slaughterhouses, meat and milk and dairies regulations would more conveniently remain with the new Department of Agriculture Fisheries and Food But of course in all these matters regulations would have to be made jointly and there would be the closest consultation Primary responsibility for the new Food Hygiene Advisory Council it was intended should go to the Ministry of Health

QUESTION TIME

Nuclear Radiation

Replying to a question, Sir WINSTON CHURCHILL, the Prime Minister, said that the Government had already invited the Medical Research Council to review the existing scientific information on the medical aspects of nuclear radiation and to prepare a report The report would cover the medical aspects of nuclear radiation, including the genetic aspects It would be published as a white paper

Mr ERIC FLETCHER asked the parliamentary secretary to the Ministry of Works, as representing the Lord President of the Council, what progress had been made in the investigations concerning the genetic effects of increased radioactivity due to the explosion of nuclear weapons, and when he expected that it would be possible to begin research on measures designed to counteract these effects—Mr J R BEVINS replied Research on the genetic effects of radioactivity is necessarily of a long term nature, but a certain amount of progress has been made and results are published in the scientific press as they become available The Medical Research Council's programme has, for the past eight years, included work on means of protection against the effects of radiation

Mr FLETCHER Does the Minister realise that the public are becoming increasingly concerned to know what British scientists feel about the precise effect on the future of the human race of these nuclear explosions, are anxious to have full information in a convenient form, and are also anxious that the Minister's department should be able to assure them that some research is being conducted into what counter measures can be taken?—Mr BEVINS The urgency of the work is well appreciated, and it is, of course, going forward on an expanding scale However, I am bound to say that none of the radioprotectors or regenerators that have so far been discovered have any effect on genetic damage to animals or human beings

Protection of Hospital Workers

Replying to a question, Miss PATRICIA HORNSBY-SMITH said that it was the normal practice of hospitals in the National Health Service to observe the recommendations of the British X-ray and Radium Protection Committee about protection and working conditions in X ray and radium departments This code of practice was, however, in some respects out of date, and the Minister of Health hoped to bring into operation shortly a revised code approved by the Radioactive Substances Advisory Committee which included a section on the disposal of radioactive waste

Allegation against M R C Refuted

Mr PETER FREEMAN asked the parliamentary secretary to the Ministry of Works whether he was aware that a number of cases had recently been brought to the courts of cat stealing on a large scale and that several people had been convicted for this offence, that these cats had been stolen for sale to medical research laboratories, as admitted in court, that the cost of the defence and the fines had in some cases been paid by the Medical Research Council and that they had employed the same counsel, details about whom have been sent to him, in most of the cases, what authority existed for the payment of such expenses out of public funds, how much had been spent on each of these cases in the last six months, and what action he proposed to take to prevent a recurrence of such incidents—Mr BEVINS replied I am glad to have the opportunity of stating quite unequivocally, that there is no truth whatever in the allegations against the Medical Research Council

In answer to further questions he added that the Lord President had been into the matter with the most meticulous care and he was satisfied that none of the suggestions contained in the question was based on evidence The barrister whose name was supplied to the Lord President by Mr Freeman had had no contacts of any sort with the M.R C Defendants in court sometimes told the truth and sometimes they did not

Mr Freeman said that he would raise the matter again at the earliest possible moment

Doctors' Telephones

Replying to a question, Mr IAIN MACLEOD, the Minister of Health said that he was not prepared to seek powers to ensure that general practitioners in the National Health Service should be available to their patients on the telephone But, pre judging any entirely exceptional case, it seemed him as a general matter of common sense that a oviding general medical services was not in a proper position to fulfil his obligations to visit his patients their condition so required if he did not make re arrangements for them to communicate with him by telep

Leprosy Treatment in the Colonies

Mr L W B TEELING asked the Secretary of State for Colonies how many leprosy hospitals there were in the C and in what Colonies patients with leprosy were refused mission, even when suitably accompanied, to visit towns from the leprosy centres—Mr HENRY HOPKINSON, Minister State for the Colonies, replied There is an institution for treatment of leprosy in every Colony in which the disease endemic, either in leprosy hospitals, outpatient departments general hospitals, or in separate settlements or villages. Con of patients under treatment with the general public is related the risk of infection in each case Mr TEELING Is the Mini aware that recently there have been so many discoveries w regard to leprosy that it is considered by those who a studying this disease that it is no longer really necessary have these completely isolated settlements? Will he m sure that the Colonial Office is keeping that in mind?

Dr BARNETT STROSS May we take it that it is n accepted that leprosy is not a dangerously infectious contagious disease and that free movement does not nec sarily bring danger to the community at large?—M HOPKINSON Yes, sir The danger depends, of course the specific case, but in the general way people still retain very serious dread of the disease Only education as to effects of modern drugs, and so on, will eradicate that fe

Obituary

GEORGE FORD PETRIE

M D Aberd

Dr George Petrie, lately retired from the staff the Lister Institute of Preventive Medicine, died at age of 81 on March 17

He graduated in medicine from Aberdeen Unive in 1898 and five years later took the M D with honours As an undergraduate he had shown lean towards pathology and was awarded medals in th subject After qualification he became for a time assistant in general practice till, in 1902, he was appoint assistant bacteriologist to the Lister Institute, w in the serum department at Elstree under the Dr George Dean In 1905 he served as a member of Plague Commission under the late Sir Charles Ma in India and again from 1911 to 1914 under Dr Ch Todd in Egypt During the first world war he commissioned in the R A M C and worked as a ge bacteriologist in France After the war he returned the Lister Institute, and in 1919 he rejoined the department at Elstree, of which he was ap bacteriologist-in-charge in 1926 From then until retirement in 1939 he carried out investigations into wide variety of bacteriological and immuno problems, and was responsible for the production standardisation of many antisera It was on the foundations laid by him that the large-scale producti of potent antitetanic serum was based During the war he came out of retirement for some years to re charge of the serum department of the Lister Institute

Dr Petrie's publications included many papers deal with epidemiological, bacteriological, and immun logical subjects In 1934 he published a book with late Sir Alexander Fleming on recent advances in vacc and serum therapy During his retirement he arrang an anthology of *British Medical Science and Practice*

C T writes "Petrie was a conscientious work He was a delightful companion with many interest particularly in natural history He was also a great read especially of the more classic English literature In earlier years he was an incessant smoker and someti in the middle of a meal he would absentmindedly li his pipe and go on talking, having forgotten all about next course During my long absence from England lost intimate touch with the details of his work, but managed generally to meet almost every year I sh miss him sadly"

Mr A F MACCALLAN, consulting ophthalmic surge to the Westminster Hospital, London, died on Mar 31 at the age of 82

In England Now

Running Commentary by Peripatetic Correspondents

THE sport of underwater swimming, fishing and photo-aphy is becoming the rage, with clubs devoted to it ringing up all round (one in this country is said to have thousand members) A spate of books and films, both tional and documentary, has stimulated Tom, Dick, d Harry with their wives and children, to emulate ans and Lotte Hass, Captain Cousteau and the Criles it is not surprising that the First International xhibition of Underwater Exploration and Photography now being held.[1] Most of the exhibits are photographs many familiar and some unfamiliar incidents from the ooks and films, and some show a few of the difficulties perienced by Walt Disney's photographers, one of hom had to stand on his head to adjust the camera. trange fishes (who will be the first to photograph the elacanthus in its natural habitat ?) and beautiful coral ardens abound and H G Vevers shows his carpet of rittle Starfish at Plymouth. Other exhibits include atertight cases to enable ordinary cameras to be used nder the sea, a watertight compass (presumably to revent taking the wrong turning) and watertight inoculars (as already used by bird watchers in marshes)

And last, but decidedly not least, there is, posing lternately in sea green and in snow white diving ostume and wearing frogman's flippers, a real live mermaid who made me want to visit Copenhagen to ind out if Hans Andersen's had become detached from er rock.

* * *

When the canal was frozen the rats having nowhere lse to go came to us. So I went to see the sanitary nspector who said if I put five bob down he would send chap round to get rid of them When I got home at unch time I said to my wife

Has Ratty come ?

' Yes

What's he say ?

" Nothing

So I went to have a chat with the Rat Man Rather posh chap with a corduroy cap very straight on his head

"I didn't like to say anything to your wife he said; ' women are easily upset but I don't think you ought to leave the child in the pram.

The child ?

Well you never know

Then he took me round the garden The place was like a Swiss cheese with rat holes

Well where do we go from here ? I said

I will bait the holes.

And that will be the end of them ?

" They don't die straight away That was the old method They would die near the hole and then the next rat would come along and smell a rat, so to speak, and wouldn't touch the bait. With this new bait they got internal hæmorrhage and die three or four days later

That's clever

" It was worked out in America

Well work it out here chum and I'll be grateful.

When Ratty came back on the following Thursday he inspected the bait and most of it had been taken

Has it been taken ?

Yes indeed. This is a very effective method

Where do they die ?

Well it *could* be in the house

In the house !

Could be Or it could be outside If they die in the house under the floor boards they won't smell unless they happen to be near hot pipes.

Shall we block the holes up now ?

No no I shall lay more bait and if that is touched there will still be more around

And how long does this caper go on for ? "

If it *does* go on it means the drains are fractured

Why bring in the drains ? That's expensive If they have to dig up the drains it'll cost a mint

"We can find out if the drains are fractured without having to dig them up by the smoke test

' Thank God

But it fills the house with very acrid fumes Your wife should be warned

If I warn her any more she'll be off '

' The smoke is blown down the w c. pan and if there is a fracture it comes up in the garden at the site of fracture

Sounds simple Go ahead and let me know the worst

I went in to the wife.

Have they gone yet ? " she asked

" Not quite He's going to fill the house with smoke '

What for ?

' To see if the drains are fractured "

Well I think it's ridiculous when we had rats in Rhos we put down traps and caught them

" That's out of date You must move with the times, old flower "

On the following Monday I met Ratty in the garden

Well what's the form ?

I'm very disturbed. They should have gone but they haven't The smoke test was negative '

" Well I'm not a pro at this game but I think all the holes should be plugged up right away The house will be in ruins if something doesn't happen

You could stop them up but you might be imprisoning live rats under the house and they will gnaw their way up through the floor boards, which would be undesirable '

So I went in to see my wife.

' Have they gone yet ? "

No Any minute now they'll be coming up through the floor boards '

My wife is a woman of few words. " Rats. she said.

* * *

We were gratified that our eldest son should be following in both our footsteps, and thought we might help him in his biology for first M B Primed with your leading article on Clonal Ageing we lately delivered at the breakfast table what we thought was a masterly account of the habits of the dimly remembered paramecium There was a disappointing lack of awe at our erudition Instead, as might have been foreseen, we are now referred to as ' the ageing clones.

* * *

Your leader on Man in Space was perfectly timed; for it was in my hands just ten days before my son aged 10, returned home for the Easter holidays. With what nonchalance was I able to meet the abrupt inquiry Dad do you know about the Heat Barrier ? "

But my relief was short-lived—for now I don't know which Heat Barrier Jonathan was discussing There is a band of heat around the Earth of a limit not given which holds toxic amounts of ozone and a high temperature not specified Further on we come to Space Space is not defined in this sense by my edition of the *Concise Oxford Dictionary*—I must get an *Encyclopædia Britannica*—but it has a vacuum temperature of 4000 F

It may be the step from the great cold into Space that Jonathan has in mind I think that this must be the Heat Barrier because I now learn that when you reach the Heat Barrier you are disintegrated, which is poor reward for having survived the discomforts, hazards, and minor sound, heat, and cold barriers earlier in the voyage

* * *

A somewhat fussy elderly lady came to see me after an interval of some years. I examined her; we exchanged the usual social chit-chat about weather and shortcomings of this year's sweet peas; she sat waiting for her E.C 10 Unfortunately I am a man who-never forgets-a face-but has no-memory for names I did not wish to offend an old patient; but I racked my brains in vain At last inspiration came to me I have forgotten how to spell your name ' I said innocently ' JONES the lady replied tersely and never returned to my surgery

Letters to the Editor

GENETIC EFFECTS OF THERMONUCLEAR EXPLOSIONS

SIR,—Some of the more pessimistic views recently expressed on the genetic dangers of peace-time thermonuclear explosions are unrealistic They take no account of the eugenic counter-measures which mankind will surely take

No reliable figures for the effect of a given dose of radiation on mutation-rates in man are available, but it is not unreasonable to suppose, as you do in your annotation last week, that two explosions yearly might double the natural level of radiation and hence the mutation rate An increasing programme of explosions would have a correspondingly greater effect But this does not mean that the human species will undergo irreversible genetic deterioration

First there is the question whether an increase in mutation rate is harmful Some human geneticists believe that it is impossible to say whether a gene is "good" or "bad" in its effects A mutation lethal in the homozygous state may be beneficial in the heterozygous state Further, they claim that it is impossible to predict the future, so that a mutation now harmful may be useful in future environments These are not my own beliefs and so I will not elaborate them further It is, I think, probable that most mutations are harmful, that most of them are either recessive or dominants of low penetrance, and that ultimately the balancing by natural selection even of the present mutation-rate requires fairly high miscarriage, stillbirth, and childhood-death rates

Even so the dangerous effects of an increase in the mutation rate can be prevented provided that mankind is prepared to undertake control of his own evolution Surely a few groups at least of such a resilient species as our own will make this attempt some time in the centuries before the increased mutation-rate can cause a disastrous fall in average fitness The initiative will probably come, not from governments, but within individual alert and responsible families

The great potential effectiveness of such artificial selection depends on the fact that most mutations affect only a small proportion of those who possess them, the remainder being apparently healthy carriers This is the case whether they are mainly dominants of low penetrance or recessives exerting an effect only in the homozygous state Within the next century or so it will be possible to identify most of these genes in the carrier state This is already possible with the genes responsible for thalassæmia major, sickle cell anæmia, and one form of sex linked choroidoretinal degeneration Once symptomless carriers can be recognised it is possible to encourage them to plan a family size below replacement rate For example, if the heterozygotes for any rare recessively determined condition aim at a family size of only two children and thus have a fertility, say, of only three quarters of those homozygous for the normal gene at that locus, this will prevent any increase in the frequency of the gene concerned even though the mutation rate is increased, say, a hundredfold from 1/40,000 to 1/400

This is selection against a single mutation Selection against a great many mutations naturally means that selection against any one of them must be less intense We are probably all carriers of some deleterious mutations Once the knowledge is available the aim of artificial selection would be to lower the fertility of those with

total number of deleterious mutations But

mass selection can have considerable effect

tions are hypothetical One estimate, by H J Muller,[1] is that the present mutation rate would be balanced if the 3% of the population with the highest number of mutations did not have children A sliding scale relating the planned family size of each individual couple to the number of mutations they possess would be still more effective in eliminating mutations In a real emergency unorthodox methods of achieving highly selective reproduction will be available, such as the widespread use of artificial insemination with donor semen almost free from mutations

The task of determining how many mutations each individual carries is obviously a major one, it may well become one of the chief tasks of the family doctor But it is possible meanwhile that much could be done by purely phenotypic selection—a process which is already occurring among the groups who effectively plan the size of their families

Any talk, therefore, of the end of the human race from peace-time experimental thermonuclear explosions is unjustified, provided that man's knowledge of human inheritance advances and he is willing to apply it Even with current mutation rates, some artificial selection will ultimately be needed to maintain our present health standards Once the practice of such artificial selection is accepted it could keep the balance against considerably higher mutation-rates Even the danger of wa with thermonuclear weapons, to which Dr Summerskil drew attention so dramatically in the House of Common the week before last,[2] would seem to lie more in the los of our scientific knowledge of how to deal with th increased mutation rate than in the increased mutation themselves But if war seemed imminent it woul obviously be a prudent precaution to store considerabl amounts of germ-plasm in radiation proof container in the hope that survivors might retain the skill to us this rather than their own damaged germ-plasm fo reproduction

Orpington Kent C O CARTER

COUNTING THE SWABS

SIR,—Every surgeon will agree with Mr Riddell statement (March 26) that it is the instrument nurse duty, and hers alone, to count the swabs before and aft an operation The surgeon must take care that no loo swab ever enters the abdomen, that all small ones a on holders and all large ones have a corner or a tap to which a forceps is attached, lying outside the abd minal cavity At the conclusion of the operation h must ask her if the count is correct, and help her i the search if it is not But if he attempts to do th counting himself, that essential element in all safet precautions—the complete responsibility of one individu for each item—is lost

There may be considerable anxiety when the coun is not correct The surgeon makes a thorough search fo the missing swab It is not in the operation site It ma turn up between the towels and the patient's body wrapped round the specimen that has been sent to th pathologist, or even stuck between the sole and heel o the assistant's boot

I was faced with such a problem four years ago

After three counts and three careful searches in the abdomen one large swab was still missing The patient had by now had enough, and I was forced to close the abdomen I consulted my solicitors and was advised to tell the patient frankly that a swab was missing at the end of the operation, that I had searched for it, and that I did not think it was in the abdomen He was first incredulous, then deeply distressed His postoperative course was stormy He ran a temperature He and I felt (or thought we felt) a lump in the left hypochondrium However he made a slow, but satisfactory, recovery I saw him once a month for six months, and en at three-monthly intervals for two years, but the missing wab has never been accounted for

---

[1] Muller H J *J hum Genet* 1950 2, 111

[2] See *Lancet*, April 2 1955, p 725

Anxiety over the missing swab has been largely olished by the use for small swabs at any rate, of auze into which an opaque strand has been woven hese radio-opaque sponges have been in regular use in merica for at least ten years and they are now available n this country Their use in the case I have recounted ould have saved the equivalent of ten years wear and ear on the coronary circulation of two people

London, W 1 HENEAGE OGILVIE

TUBERCULOSIS IN IMMIGRANTS

SIR,—I am reluctant to prolong a discussion to which ou have already given much space but I must challenge he inference which Dr Doig (March 19) draws from his igures of tuberculosis mortality and morbidity in the sland of Lewis

The percentages of tuberculin positive children even in owns, are not high; and it is quite usual in remote districts o find small areas in which there are many positive tuberculin eactors, among whom new cases of tuberculosis will appear nd who because they are so far from hospital and radiological facilities, may die of the disease It is not so long since Dr Doig was pointing out (Jan 15) that it was the tuberculin positive young adults from his island who developed tuberculosis when they left home to work, and he cannot be permitted to argue both ways If he is right however in his assumption that a high death rate from tuberculosis is consistent with a high tuberculin negative rate then Lewis is unique because elsewhere the opposite is true A typical example is in the Philippines, where over 50% of 3 year-old children, 80% of 10 year-old children, and 90–100% of adults over 20 react to tuberculin[1] Tuberculosis is the leading cause of death among Filipinos Palmer and Shaw[2] in an extensive investigation of the results of B C G vaccination, found a negligible number of new cases and deaths in vaccinated persons and in unvaccinated tuberculin negative controls but they found that morbidity and mortality from tuberculosis were almost confined to those who were naturally tuberculin positive at the beginning of the survey

The same applies to Ireland The idea that tuberculosis arrived here recently is quite fantastic it was recorded as a cause of death in Irish cities in the 17th century and I have no doubt that it was known much earlier The enormous increase in the population of Ireland between 1695 and 1841 from 1 million to 8 million was mainly in the rural population in tenant farmers and in labourers[3] The subsequent overcrowding and malnutrition made an epidemic of tuberculosis inevitable and the great famine of 1847 gave a tragic impetus to the disease throughout the 19th century Death and emigration reduced the population as rapidly as it had increased, and many rural areas which had formerly been congested became sparsely populated Regrettable as this was from a national point of view it had the effect of limiting the spread of infection and in recent years as Dr Flynn and Dr Joyce (Feb 26) rightly stated modern methods of diagnosis and treatment have reduced the amount of disease still further It is important to remember therefore that if many young people in the Irish countryside are tuberculin negative it is not because infection has not yet reached their districts, but because it has already left them Certainly in Northern Ireland and apparently in Eire as well tuberculosis in rural areas is no longer a problem of any size or importance It is prevalent only in the cities and large towns which for so long have been thoroughly tuberculinised and which contain the highest percentages of young positive tuberculin reactors[3]

The Irish are not the only immigrants amongst whom tuberculosis has been common. Plunkett[4] has drawn attention to the problem of tuberculosis among displaced persons from Europe who were admitted to the United States after the 1939–45 war In Israel the incidence of tuberculosis is now several times greater than it was in 1947 and this is attributable to indiscriminate mass immigration.[5] No-one would attempt to argue that displaced persons from Europe and Jewish immigrants in Israel were lacking in experience of tuberculous infection or to deny that they had taken their infection with them But Dr Hess and Dr Macdonald (Feb 12) believe without having carried out a single preliminary test that it is the tuberculin negative Irish who develop disease in England and it seems strange that too little infection in the native country should have the same effect as too much

I do not deny that individual or even racial susceptibility can vary or that social conditions will modify the incidence of tuberculosis for better or worse, but I do insist that the intensity of infection in any country is the decisive factor in causing tuberculosis and that the elimination of infection is at present the only means we know of preventing it Ultimately the immunising *fraction of the tubercle bacillus* will almost certainly be isolated but so far there is no convincing evidence that artificial "tuberculinisation" with B C G vaccine can succeed where the natural process has so obviously failed

The task of eliminating infection is difficult but no longer impossible and the goal before us in the United Kingdom is not merely the control but the eradication of tuberculosis The task is not made easier by those who point out spurious short-cuts upon which to waste energy and resources.

B C G VACCINATION

SIR,—The points raised by Dr Webster (March 5) and Dr Loxton (March 19) are, of course, of the greatest importance in arriving at any conclusion on the value of B C G vaccination Unfortunately our knowledge on immunity in tuberculosis is still very incomplete, and at present I do not think it is possible to state the relationship of tuberculin hypersensitivity to immunity, but many authorities believe that the former is an expression of the latter although the lack of hypersensitivity does not indicate an absence of immunity

B C G vaccination is based on the assumption that recovery from a primary tuberculous infection be it caused by virulent or by attenuated bacilli, confers a certain degree of acquired resistance to subsequent infections The degree of the acquired resistance conferred will vary from individual to individual, and the possibility of developing active disease after vaccination will depend on the age of the individual, the magnitude of the infecting dose and the cellular response to the invading bacilli I agree that the last phrase begs the question, and it is by making such statements that we 'go round the mulberry bush' of immunity

It is probable that a high state of resistance to tuberculous infection is present in persons who have become desensitised by repeated infections Evi for this is found in the state of tuberculin anergy tha is attained by some persons who have worked in a high infectious environment for many years and also by th state of 'positive anergy' in children who have bee given B C G orally over a number of years Sayé[6] in his vaccination work in Barcelona is able to produc by repeated oral vaccination a state that reacts ver feebly, or not at all to the jelly patch test but still be sensitive to $^{1}/_{10}$ mg of B C G given intradermally Sayé terms this *l'allergie atténuée* or *latente* and conside it evidence of the optimum degree of resistance state corresponds to Godlowski s second type as describ by Dr Loxton Whether this state is more immune t infection than the one of tuberculin sensitivity that w are producing by the usual method of vaccination i this and many other countries has not yet been de mined If it is so, then repeated B C G vaccination by the oral method does satisfy Dr Loxton's demand "for a vaccine which will confer immunity, and will, at the same time, desensitise the patient"

May I take this opportunity to correct what might give a wrong impression in my article (Feb 12)? I stated that the relapse rate to tuberculin anergy in Ireland is 20 72% On referring to the original work of the late Dr Dorothy Price,[7] I find that this figure included an exceptional group and that a more correct figure would be 11 8% over a period of two or three years' observation In addition to the reasons I stated for the reversion rate, I am grateful to Dr St John Cowell, the medical director of the National B C G Committee, St Ultan's, for reminding me that in Eire the Swedish vaccine is used on a rural population, and the Danish on an urban one, also that the follow-up at St Ultan's was for two or more years The chances of superinfection by virulent organisms in Dublin City are greater than in the rural areas, so the reversion to tuberculin anergy will be less frequent The fact remains that reversion is an important event, and the possibility of it must be continually borne in mind in B C G vaccination campaigns, particularly in infants and young children

PURE RED-CELL APLASIA

SIR,—The case described by Dr Fountain and Dr Dales (March 12) provides another interesting example of the complexity of these unusual anæmias Their conclusion that oral cobalt therapy led to the patient's recovery could be of the greatest importance, and it will be most interesting to see, should the patient relapse, whether cobalt will again prove effective

I have given a solution of cobalt chloride (in daily doses of 100–300 mg) to two patients with "pure red-cell anæmia" This resulted in no improvement, but prolonged treatment was impossible because the patients seemed intolerant of the preparation There was certainly no immediate improvement, as in the case described by Fountain and Dales They cite the case reported by Seaman and Koler[8] in which cobalt therapy was of value in erythroid hypoplasia, though the patient did not improve until after 64 days of continuous cobalt treatment—a surprisingly long time when compared with other hæmatinics and the experience of Fountain and Dales

I wonder whether more credit should not be given by Fountain and Dales to the effect of splenectomy in their case It was followed by progressive increase in numbers of marrow erythroblasts for 3 months after the operation Apparent benefit from splenectomy was delayed for nearly a month in a somewhat similar case I have studied, and 4 months' delay for improvement in blood values after splenectomy is probably not impossible

Any means of treatment which will avoid repeated transfusions to such patients deserves energetic study Only recently a patient of ours (Chalmers and Boheimer,[9] case 1) died from hepatic cirrhosis and general siderosis although recovery from pure red cell anæmia had been complete for over 2 years and he showed no hæmatological relapse in his final illness He had previously received some 55 pints of blood at a time when erythropoiesis was absent In his terminal illness he did not want venesections performed, and it was tragic to see a death probably due to the late effects of a measure which had earlier been the sole means of keeping the patient alive

A LIVER POISON WITH UNUSUAL PROPERTIES

SIR,—Dr With has called attention (March 19) to the work of Quin[1] showing that administration of the South African plant *Lippia rehmanni* (verbenaceæ), or alcoholic extracts of the plant, to sheep causes inhibition of biliary secretion and consequent jaundice without evident hepatocellular damage He does not add that the active principle was later isolated by Rimington, Quin, and Roets,[2] and named "icterogenin" It was shown to be a triterpenoid acid and to arise in the leaves of the plant during active growth and to be translocated and stored in the fleshy root bark

Atony of the fore stomach and large intestine and bilirubinæmia regularly followed administration of 1 5 g of crystalline icterogenin by stomach-tube to sheep Fairly extensive pharmacological study showed that icterogenin inhibits the smooth muscle of the gut and the isolated, perfused heart It is mildly hæmolytic in vitro The jaundice which follows its administration by mouth is not hæmolytic, it seems, rather, that the pigment excretory function of the liver is temporarily impaired

Recently Barton and de Mayo[3] have further studied the chemistry of icterogenin and have completely elucidated its structure I am at present awaiting a new supply of material from South Africa with which the icterogenic property of the drug is to be investigated more fully in association with Dr G H Lathe and Dr B H Billing

C RIMINGTON

THE HAIR OF THE PILONIDAL SINUS

SIR,—Mr F E Weale (Jan 29) describes some ingenious histological investigations on the hairs of natal-cleft pilonidal sinuses, showing that they all lie with their roots deeply, and he concludes that "the sinuses are therefore developmental defects" His facts seem conclusive, but his conclusion depends on two assumptions (1) that this is what one would expect if the sinuses were developmental, and (2) that such an arrangement of the hairs rules out the possibility of an acquired origin

On the first point, there is no obvious reason why a developmental sequestration of skin should produce hairs running only in one direction, and Mr Weale's further assumption that the hair bearing is limited to a "fairly circumscribed area" at the cranial extremity of the sinus stretches the developmental hypothesis still further beyond what is reasonable

It is on the second main assumption that we wish particularly to comment There is a very clear explanation of why hairs should enter a natal cleft sinus with their root ends in advance One of our students—Mr E S Williams, B SC—has reminded us of the countryman's old trick of making a head of barley progress up someone's sleeve, merely by introducing it base first, and he has pointed out that the mechanics of propulsion of a hair are similar The scales of a hair are so arranged that their free ends point peripherally As a result, if a hair is stroked along its surface from the root to the periphery there is little movement of the hair, owing to the slight frictional resistance If, however, a hair is stroked from the periphery to the root, there is considerable frictional resistance from the free ends of the hair scales, and the hair is propelled in the direction of its root (One can readily confirm this by placing a hair in the palm of the hand and rubbing to and fro along its axis with a finger of the other hand)

Applying these mechanical principles to the natal cleft, shed hairs will naturally tend to lie longitudinally owing to the configuration of the cleft The normal frictional movements between the sides of the cleft will propel the hairs either cranially or caudally according to the direction in which root of the hair happens to be pointing If a sinus or is present many of the cranially propelled hairs will enter orifice invariably root first The same forces will resist expulsion of the hairs and tend to force their roots still her into the depths of the sinus. They may also drive infected hair into the intact skin and thus initiate a nidal sinus.

[1] Quin J I *Onderstepoort J vet Sci* 1933 1 501

[2] Rimington C, Quin, J I Roets G S C *Ibid* 1937 9 225

[3] Barton D H R, de Mayo, P *J chem Soc* 1953, p 887

Jp till now the one flaw in the hypothesis of the quired origin of natal-cleft pilonidal sinus has been doubt on how the hairs got in We have in the st suggested a suction mechanism and it may be that is does play a part in the digital-cleft sinuses of barbers. it in the natal-cleft pilonidal sinus we now believe that vement of the hair under frictional influences, as scribed above, is the essential factor Mr Weale's servations on the lie of hairs in a pilonidal sinus by awing attention to the hair scales have thus indirectly 1 to the filling of the one important gap in the case r the acquired origin of natal-cleft pilonidal sinuses. the acquired origin of most other varieties of pilonidal nus there has never been any doubt.

HYPOTHERMIA IN THE NEWBORN

SIR —I was very interested to read Dr Trevor Mann s tter in your issue of March 19 I agree with Dr mallpeice and Dr Everley Jones (March 26) that this ndition is no new one I have seen 24 cases in the last n years and they have all been in the winter months ovember 1 December, 8 January 5 February, 8 arch 2

Like Dr Everley Jones I call the condition sclerema eference to textbooks on the disease is disappointing t is usually dismissed in a very few lines as a rare and lmost invariably fatal disease with no seasonal incidence t certainly is not very rare many of the cases recover nd the seasonal incidence is marked

Sclerema is always present I too have purchased a low reading thermometer and the following are the emperatures recorded by me 90 5 90·4 91 90 87, 93 8 84, and 86°F

The treatment that I usually give is thyroid extract r $^{1}/_{16}$ three times a day vitamin E 5 mg daily, peni illin and warmth The majority of the babies survived I know for certain of only 5 deaths but my records are incomplete I was not aware of the danger of rapid heating and I hope that in future more temperate treatment will produce even better results

Leicester

J VERNON BRAITHWAITE

SIR —Dr Trevor Mann has performed a useful task in drawing attention to the syndrome of hypothermia neonatorum We also see a few such cases each year Although they all occur during the winter months, it is not always easy to correlate the development of the syndrome with a cold environment The rooms in which the babies have been kept have sometimes seemed to be adequately warm nor have the cases always arisen during very cold weather My last one developed during the thaw that followed a cold spell The relationship between hypothermia and sclerema is also somewhat inconstant in my experience I have had cases of severe hypothermia without sclerema and of sclerema without hypothermia

I would entirely endorse Dr Mann's remarks regarding the danger of warming these babies too rapidly but I have found that small doses of thyroid extract are beneficial

D A J WILLIAMSON

Royal Hampshire County Hospital,
Winchester

SIR,—I read with interest Dr Mann s communication I wonder if he would consider trying to warm these babies by the technique described by Khalil and Mac Keith [1] They insert into the stomach a plastic tube with a rubber balloon attached to the end Warm water is injected into it and withdrawn at intervals after it has had time to supply heat to the body—i.e to the large vessels adjacent to the stomach The method was actually used to lower the body temperature of a hyper pyrexial child but the authors state that it could be equally well used to supply heat and they suggest that it has several advantages over the method of warming patients by external heat

PAUL E POLANI

RUPTURE OF LAPAROTOMY WOUNDS

SIR,—Three weeks ago, at the conclusion of a partial gastrectomy, the aponeurotic layer of my abdominal wound was closed with interrupted sutures of nylon (no 7) sterilised by the normally approved methods. Forty-eight hours later a cough of very moderate violence caused every suture to snap at a point well clear of the knot There was no staining of the dressing either then or at its later removal, but a patch of surgical emphysema appeared on the left anterior thoracic wall giving a clue to what had happened Successful resuture with linen thread followed

This experience makes me doubt whether nylon is so perfect a suture material as is claimed by Mr Mill (March 26) If Mr Mills consults the fishing periodical of the past seven years he will find a voluminous and acid correspondence on the erratic tensile strength o nylon and certainly I cannot enthuse over a material which holds neither my fish nor my anterior abdominal wall.

London, S W 7

FRANK GREENWOOD

CONGENITALLY SHORT FRENULA OF UPPER LIP AND TONGUE

SIR,—We should like to congratulate Mr Michae Oldfield (March 12) on his exposure of two myths firstly that ' there is no such thing as tongue tie and secondly that operations on frena of tongue or lip are unnecessary and useless These two common errors arise we feel sure from two sources students are rarely, if ever taught anything about the matter and on referring to a textbook they find such negative sentences as above which have probably been copied from edition to edition without thought or verification

Operations almost identical with those described by Mr Oldfield have been done routinely at this hospital for many years when indicated To those who doubt the necessity for these little operations we would say ' try yourself to say D or T with the tongue held no higher than the lower incisor teeth ' It is quite impossible nor can L or S be pronounced clearly Take any short sentence and note how frequently these sounds are required to render speech intelligible

The frenum labii certainly sometimes causes an unsightly space between the central incisor teeth and is also the cause sometimes of an ugly sibilant lisp in speech If the frenum is abnormal it should be treated as such The teeth will come together and speech become normal—provided it is done in time and not left until adolescence Dentists sometimes say that this operation is unnecessary because the space can be eliminated by an orthodontic appliance but if the abnormal frenum persists the teeth will revert. Operation takes much less time and is more certain There is only one point on which we are not in accord with Mr Oldfield—namely, in the use of intra tracheal anæsthesia for young children

Several workers have pointed out the risks of tracheal trauma and the formation of a membranous plug and we agree Fine intranasal catheters passed to the pharynx are, we find, excellent and sufficient for such short anæsthesias, with the head dropped low no pharyngeal packing is necessary, and if one is sufficiently quick with mosquito forceps there is no loss of blood whatever Treated thus the patient need not be in hospital more than a few hours

---

[1] Khalil H H MacKeith R C. *Brit. med. J* 1954 ii, 134

' Simple division, we agree, is useless—recurrence is the rule One typical case we would cite

' A boy, aged 8, had very defective speech He had been seen by several doctors, and his mother had been told that all authorities were agreed that there was no such thing as "tongue tie", he had also had courses of speech therapy without improvement On examination an extremely short frenum linguæ was obvious His tongue could not possibly make tight contact with his palate for L, D, T, and S An operation essentially as described by Mr Oldfield was done, and with very little instruction he quickly spoke quite normally How much better, though, if the defect had been discovered in infancy and all his mother's worries and his own troubles at school had been avoided

CECILY M PICKERILL
H P PICKERILL

ENURESIS

SIR,—Your leading article (Feb 19) and the subsequent correspondence emphasise that enuresis is a symptom in which conventional concepts of medicine are inadequate Physiological, pathological, or psychopathological investigation separately will not give the whole picture, though many useful observations have been made by such means

Enuresis is a good example of an illness that should be studied "as a patch of personal biography," and as such it may go beyond the individual We should not pay undue attention to the mechanics of micturition unless there is a structural abnormality or some other relevant lesion Enuresis is more often found to be evidence of tension in relationship between the patient and his family, hence the number of instances where a child is enuretic at home but not when visiting or on holiday

Dicks[1] has said "Modern child psychiatry has long recognised that stress in a family cannot be compartmentalised We know that the whole unit is involved, even though only one member may present himself as a patient" The fact is that our investigation and understanding of the problem should go beyond the boundaries of the individual concerned "Cure" takes place with many therapeutic procedures Sometimes one patient may be "cured" only for another member of the family to take on the weight of the family disturbance with quite a different symptom

University of Leeds

J H KAHN

INACCURACY IN THE LABORATORY

SIR,—Dr Bassir's letter (March 26) welcoming freeze dried samples of blood-serum is liable to occasion some misconceptions

Firstly, the freeze dried serum is not intended as a replacement of the standard solution in any method the intention is to provide a serum containing certain constituents in known concentration wherewith a laboratory can assess the extent of the inaccuracy with which a given determination is carried out

Secondly, the international survey with similar material carried out last year was not available to all laboratories, and, because the results were not available until some time later, was unlikely to be very useful to the individual laboratory as a control of the standard of its work. The object of the international survey was to confirm that the results of a given determination on a given serum vary considerably from one laboratory to another, this was already well known in this country and in the U.S.A, but it may be that the survey served a useful purpose in convincing some European pathologists

One can only agree with Dr Bassir that a thorough overhaul of our existing methods, apparatus, conditions [illegible] and so forth is desirable, with the object of detecting and eliminating the causes of inaccuracy Dr Bassir asks whether the clinical value of the laboratory warrants such an effort If laboratory investigations are to be carried out at all, the results should be sufficiently accurate to be clinically useful, the various surveys have revealed that in many laboratories such a standard is far from being achieved

Sheffield

ARTHUR JORDAN

MENTAL HEALTH AND PUBLIC HEALTH

SIR,—Dr Cameron asserts (March 12) "There is mention of psychology in the syllabus of general trainı of the General Nursing Council for Scotland"

Yet on p 6 of the syllabus there is a main heading, Hum Relationships, with six subheadings, and on p 13, under t heading, Mental Disorders, there are subheadings on t relationship between physical and mental illness, psych somatic disorders, psychoneurosis, and psychosis

Again, by quoting a single sentence from an addre by myself, he gives a false impression of the amount instruction in the psychology of development and alli subjects provided for nurses taking the subseque training for the health visitors' certificate

In Aberdeen a mental health course was recently organis to bring the knowledge of the older health visitors up to t level of their more recently trained successors this cou lasted for over 40 hours, despite the fact that even these ol health visitors were not at the start of the course complet without psychological training

Dr Cameron has really provided no evidence to refu the conclusions of the London Study Group

Health and Welfare Department,
Aberdeen

I A G MACQUEEN

ERETHISM

SIR,—In his most interesting article (March Dr Aldren Turner mentions that the term erethism likely to have been coined not from ἐρυθρός but fro ἐρεθίζειν

There can be no doubt about the etymology of erethis which is almost the transliteration of the Greek *ἐρεθισ* (excitation, irritation) Nevertheless the word erythism been used with the same meaning, and thence the suggest of *ἐρυθρός* as its possible derivation This, however, wo be not only highly irrelevant and inappropriate, but a verbally incorrect, for the English word should be erythri —a meaningless monstrosity

Yet even erethism is not a very fortunate term for t condition it is meant to describe, as it denotes a (consta state of excitation and not a morbid increase of the corr ponding quality Thus, while in English texts the wo irritability is used in connection with erethism, the Gre textbooks use the word *ευερέθιστος* (hyperexcitable)

Unfortunately the term is now well establishe and there is little hope of correcting it

Bethlem Royal Hospital
Beckenham Kent

G M JACOBIDES

HANDWRITING AND THE PSYCHE

SIR,—Your annotation (March 26) reads as if no wor had previously been done on this subject There is a va literature on handwriting by Continental and America authors Everything mentioned in your article is know to students of handwriting who are acquainted with th work of M Pulver and J Jacoby—to mention only two

Handwriting is an expression of the personality including its development or deterioration Neurotic o psychotic trends are detectable by those who know the job I remember Jacoby showing us the signature o Hitler, which had been smuggled out of Germany durin the last stage of the war, and the disintegration, compared with earlier specimens, enabled Jacoby to detect the mental decline which was confirmed by later event

IRST-AID TREATMENT OF HEAD INJURIES

IR,—In your annotation of March 26 you make a eralised statement about first-aid manuals, which, n say ignore ' modern knowledge regarding the causes death after head injury the grave dangers of inhala n asphyxia in the unconscious patient have not yet ered into these manuals."

It is a pity that you did not refer to the instructions. ven in the *British Red Cross First Aid Manual* No 1 0th ed. 1952) There, on p 226, the general rules for st aid treatment of unconsciousness read as follows :

> Lay the patient *on his side* with uppermost leg flexed at p and knee, or face downwards with head to one side to event any vomit or blood from entering the windpipe and keep the tongue clear of the airway

London HAROLD E WHITTINGHAM

SIR,—The importance of maintaining a clear airway the unconscious patient is one of the primary duties the first-aid worker This is laid down in the manual n *First Aid to the Injured* (40th ed , p 162), issued by e St. John Ambulance Association :

> General rules for treatment of insensibility :
> (1) In cases of asphyxia perform artificial respiration.
> (2) If breathing is present, lay the patient on his back with head turned to one side
> (3) Do not leave the patient until he has been placed in the charge of another responsible person

As a divisional surgeon I have emphasised these points n my lectures for years. In first-aid competitions I have een candidates lose marks heavily for omitting obser ation of them. This makes it difficult for me to agree with our statement that first aid manuals give instruction hich ' ignores modern knowledge regarding the causes f death after head injury '

London, W 1 GILES ROMANES

*** The passage quoted by Sir Harold Whittingham is nfortunately followed by the words 'Alternatively lace patient as in fig 100 ' Here we see an illustration f the patient laid flat on his back with his head to one ide (see also p 228 of Red Cross manual) as is also dvocated by Mr Romanes in his letter This position s undesirable after head injuries (1) because it does not rovide adequate postural drainage, and (2) because otation of the head and neck can be very dangerous if as is by no means rare) the patient has a broken neck s well as a head injury.—ED L

METALLIC POISONS AND THE NERVOUS SYSTEM

SIR,—May I add these brief details of two British cases of industrial lead poisoning in adults which have been treated with calcium ethylenediamine tetra-acetate (E D T A.) to the three American cases cited by Dr Aldren Turner (March 26)

CASE 1 —The patient was a man, aged 42 who was employed in a lead smelting works on a refining process. He was seen by his private doctor who diagnosed lead poisoning but on arrival in hospital was thought to be a surgical emergency When seen by us twenty four hours later he gave a history of a similar illness, which had been called lead poisoning some years before when in the same work.

He was lying still, pale and trembling, and in obvious pain round the umbilicus His bowels had not moved for four days, and he occasionally vomited yellow fluid. He was edentulous with no blue line and his abdomen was soft. His hæmoglobin was 68% While calcium E.D T.A. was being obtained from a distant town he was given an immediate intravenous injection of calcium gluconate followed by two subsequent injections. By the time the calcium E D T.A. arrived the pain had gone but 1 g dissolved in 600 ml. 5% sterile dextrose in distilled water was given twice daily for five days

CASE 2 —The patient had complained of gradually increasing abdominal pain for three weeks, with vomiting and constipation. The pain was gripping and ill localised, and tended to move from the centre towards the right of the abdomen He had passed no motions or wind for two days. He was employed in a shipyard ; his work was to pile old paint tins, light a fire beneath them, and then, after the paint had been burned off scour them out with a wire brush A dust-mask was provided by the management but was not used

The patient had a good colour his tongue was furred ; he had upper dentures but his own lower teeth with a well marked blue line His temperature was 99 9°F, and he was tender in the right iliac fossa. He had a left nephrectomy scar Surgical opinion was that he had no acute surgical condition. His hæmoglobin was 82%. He was watched for twenty four hours, during which his condition appeared to be improving, and was given the same dose of calcium E.D T.A. as in the first case He made an uninterrupted recovery

In these two cases the total dose of calcium E.D T.A. was only 10 g , compared to 30 g reported by Foreman et al [1] but it was given at 2 g per day, as in their cases. This treatment led to clinical recovery without complications

Industrial Health,
University of Durham R. C BROWNE

MELANOPHORE-EXPANDING ACTIVITY OF HUMAN PITUITARY GLAND

SIR —Dr Fraser (March 5) suggests that the melanophore-expanding substance which we have demonstrated in human pituitary tissue may be adrenaline There are three reasons why this is unlikely

We have never been able to demonstrate that adrenaline behaves like corticotrophin or melanocyte-stimulating hormone with respect to oxycellulose Nor have we been able to show that the *Xenopus lævis* used in this laboratory are particularly sensitive to adrenaline Doses of the order of 100 µg are necessary to produce detectable darkening and these are usually associated with marked mucus secretion by the animals. The pituitary extract which we prepared caused no secretion of mucus and produced a darkening in considerable excess of that caused by adrenaline.

CONCOMITANT GASTRIC AND DUODENAL ULCERS

SIR —In my recent article (Feb 5) I said that the well recognised association between duodenal ulcer and hiatus hernia had not been explained

I then pointed out that the occurrence of heartburn in patients with duodenal ulcer was an indication that gastric retention and œsophageal reflux were occurring I went on to suggest that reflux œsophagitis by causing spasm of the longitudinal muscle of the œsophagus, in due course dragged part of the stomach into the chest.

I have since re-read the chapter on reflux œsophagitis in R. H Franklin s monograph on the œsophagus,[2] and I find that, though he does not go so far as I did in expressing the view that all hiatus hernias with short œsophaguses are preceded by œsophagitis and caused by spastic œsophageal shortening he does describe the association between duodenal ulcer and reflux œsophagitis and clearly explains how this may increase if not initiate the gastric herniation.

Plainly this was the source of what I mistakenly thought was my own idea and I regret not having recognised and acknowledged it at the time.

London, W 1 H. DAINTREE JOHNSON

Royal College of Surgeons of England

The following Hunterian lectures are to be given at the college, Lincoln's Inn Fields London, W C 2 on Tuesday, April 19, Mr John Foster will speak on current methods of treatment of idiopathic stricture of the valve of Krause, on *Thursday, April 21, Mr Norman Barrett* will speak on primary tumours of rib, and on Thursday, April 28, Dr W T Cooke will speak on nutritional and metabolic factors in the ætiology and treatment of regional ileitis All the lectures will be held at 5 P M

Royal College of Physicians of Edinburgh

Karl Duncanson Fellowship for Medical Research—The council of the college is shortly to make an award for this fellowship (£600 for two years to begin on Oct 1) Applications must be sent before May 7 to the secretary of the college, 9, Queen Street, Edinburgh, 2

Christian Medical Fellowship

This fellowship is to hold house-parties for doctors and their families from May 6 to 9 at Windermere, and from May 20 to 23 at Bournemouth Further particulars may be had from the secretary, 39, Bedford Square, London, W C 1

Royal Statistical Society

Study Circle on Medical Statistics—On Tuesday, April 26, at 6 P M, at the Westminster Medical School, Horseferry Road, S W 1, Dr J N Morris will speak on Hypotheses on Coronary Artery Disease

Wessex Rahere Club

A dinner of this club will be held at the Royal Clarence Hotel, Exeter, on Saturday, April 30 Membership of the club is open to all Barts men practising in the West Country Further details may be had from Mr A Daunt Bateman, the hon secretary, 11, The Circus, Bath

Health Education Summer School

The summer school for 1955 organised by the Central Council for Health Education will be held at Bangor, North Wales, from Aug 16 to 26 The theme will be Opportunities and Methods in Health Education Applications should be sent to the medical director of the council, Tavistock House, London, W C 1

Orthopædics in Scotland

Since the Scottish Orthopædic Council was set up in 1942 it has distributed on behalf of the Lord Nuffield Fund for Cripples over £24,000 to orthopædic clinics, educational establishments for cripple children, and other aids to cripples in Scotland In addition the Nuffield trustees have made grants of £26,500 for hospital developments at Philipshill, Busby, and Princess Margaret Rose Hospital in Edinburgh The council has now agreed to dissolve since "orthopædic services were now firmly established in all five regions of Scotland, and therefore the work for which the Council had been formed had been accomplished" As part of the winding up process the Nuffield trustees have agreed with the council to allocate £15,000 for the erection of occupational therapy and workshop departments at the proposed spinal injuries unit at Edenhall, Musselburgh, and to make a grant of £2000 towards the extension of the residential training establishment for severely handicapped girls at Anton House, Broughty

Doctors and the Press

At an exploratory meeting between representatives of the Press organisations and the medical profession, held at British Medical Association House on March 29, it was decided to set up a committee to examine the relations between the Press and the medical profession, and to formulate proposals for further consideration The following doctors were appointed to the committee Dr H Guy Dain, Sir Harold Boldero, Dr R Forbes, Dr F Gray, Dr J G M Hamilton, Mr J R Nicholson Lailey, Dr. A. Talbot Rogers, and Dr W Woolley The first meeting will be held on Wednesday, April 27

THE URÆMIAS *

G. M. BULL
M.D. Cape Town, F.R.C.P.
ROFESSOR OF MEDICINE IN THE QUEEN'S UNIVERSITY, BELFAST

(concluded from p. 736)

PRINCIPLES OF TREATMENT

The uræmias arise because of an imbalance between he rates of intake or production of chemical substances n the body and their rates of excretion by the kidney t is clear from this concept of imbalance that we have vailable two main lines of therapy: we may improve enal function, if that is possible; or we may so adjust he intake or the production of chemical substances that normal balance is achieved despite reduced renal unction The main lines of treatment are

Adjust intake and rate of endogenous production of chemical substances to balance their rates of excretion when the kidneys are working at their maximum efficiency

(1) IMPROVE RENAL FUNCTION
  (a) Specific therapy depending on the cause
  (b) Correct circulatory renal insufficiency
(2) ADJUST INTAKE AND RATE OF PRODUCTION OF SUBSTANCES
  (a) *Reduce Katabolism*
    (1) Combat infection.
    (2) Hormone therapy
    (3) Protein-sparing diet.
  (b) *Adjust Intake of H_2O Na K Cl and N*
    (1) To correct imbalance
    (2) To maintain balance
(3) TREATMENT OF SYMPTOMS
  Anæmia, nausea and vomiting stomatitis, diarrhœa convulsions, insomnia, delirium hypertension.

Measures to Improve Renal Function

Many disease processes may reduce renal function and therapy will depend on the type All may be placed in one of three groups—obstructions true renal lesions, and circulatory renal insufficiency (extrarenal uræmia) The treatment of the obstructions is obvious In the second group, due to actual kidney damage, treatment is less satisfactory In some varieties such as acute pyelonephritis specific therapy is possible and in others, such as the hypercalcæmias and other toxic nephropathies improvement may take place when the cause is removed In the majority, however no specific treatment is yet available The third group—the circulatory renal insufficiences—is so important that it will be considered in more detail

Circulatory renal insufficiency is a better term than the older extrarenal uræmia because it indicates how is type of failure arises. Whenever the general circula on becomes inadequate for any reason the distribution blood flow through the body is altered circulation rough less vital areas is reduced while circulation rough the brain and heart muscle is relatively little fected The kidney which normally receives about a fth of the total cardiac output at rest now receives uch less; and as its function depends on a high rate blood flow renal failure results—circulatory renal ilure The primary cause is the general circulatory isturbance and this may arise either because of heart ilure (pump failure) or because of peripheral circulatory ilure (insufficient filling of the pump) All grades of enal insufficiency may be seen including complete bsence of renal function and death may result Circu atory renal insufficiency in its pure form recovers rapidly and completely on restoration of the general circulation and is one of the most satisfactory causes of the uræmias to treat

It is very important to remember that combinations of circulatory renal insufficiency with the other two groups of renal failure are common

For example a patient with chronic diffuse glomerulonephritis may develop congestive cardiac failure because of the accompanying hypertension and as a result, have a further reduction in renal function Treatment of the congestive cardiac failure will considerably improve renal function (table II) Another patient with a similar chronic renal lesion may lose water and salt by vomiting or by diarrhœa, or because of an osmotic diuresis, and so develop oligæmia with consequent circulatory failure further lowering his already reduced renal function Treatment will improve him considerably Fig 15 illustrates a case of this type

TABLE II—IMPROVEMENT IN RENAL FUNCTION AFTER TREATMENT OF CONGESTIVE CARDIAC FAILURE

Sign	Nov 15 1948	Nov 26 1948
Right auricular pressure (cm. above sternal angle)	+ [illegible]	−4
Cardiac output (litres per min.)	2 8	4 8
Effective renal plasma flow (ml. per min.)	41	95
Glomerular filtration-rate (ml per min.)	15	27
Blood urea (mg per 100 ml.)	190	90

The only treatment given between these dates was digitalis and rest in bed

Much the same may happen after release of urinary tract obstructions Water and salt may be washed out on the flood of an osmotic diuresis, so causing oligæmia Temporary improvement follows the release of the obstruction and then circulatory renal insufficiency sets in

Not only may renal lesions cause circulatory insufficiency, but the reverse may happen Any severe or long standing circulatory insufficiency may cause such a degree of oxygen lack in the kidney that the renal cells die, giving the histological picture of acute tubular necrosis

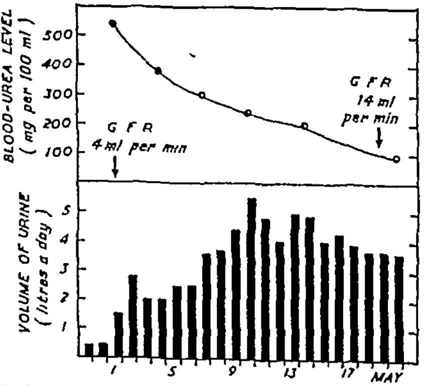

Fig 15—Effect of correction of circulatory renal insufficiency in a patient with chronic renal disease.

This patient with chronic pyelonephritis, was in a severe state of circulatory renal insufficiency as a result of losing salt and water in his urine and from vomiting Rehydration improved his renal function The glomerular filtration rate rose from 4 ml per min to 14 ml per min. and he lived for two more years, working most of the time

---

The Goulstonian lectures for 1955 delivered before the Royal College of Physicians of London on Jan. 18 and 20 Based on work done with Dr A. M Joekes, Dr K G Lowe and Miss B M Evans at the Postgraduate Medical School of London and with Dr R N Bock, Dr R A Womersley and Miss E Martin at Queen's University and Royal Victoria Hospital Belfast.

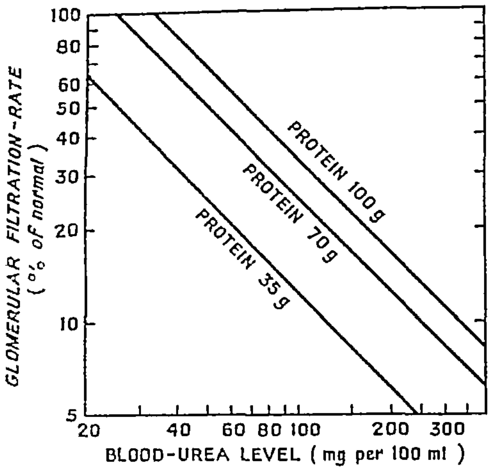

Fig 16—Approximate relation between blood urea level and glomerular filtration rate at different levels of protein intake in patients in a state of equilibrium between intake and output of nitrogen

Circulatory renal insufficiency, due to cardiac failure, is easily recognised, and its treatment well known Oligæmic circulatory insufficiency is linked with disturbances in water balance, and its management will be considered later

Thus, in every patient, we must determine the cause of the renal failure before we can attempt to improve renal function Obstructions should be relieved, and other recoverable causes of renal dysfunction sought and treated Above all, we must recognise circulatory renal insufficiency, even when combined with other causes, and treat it vigorously because it is the most amenable to treatment, and because it may lead to a more intractable type of renal failure

Adjustment of Intake and Rate of Production in the Body of Important Chemical Substances to Match their Rates of Excretion

REDUCTION OF KATABOLISM

The rate of production in the body of chemical substances, and the rate of migration of certain intracellular substances, such as potassium, into the extracellular fluid, are related to the rate of katabolism, which in turn is greatly affected by infection and is under the control of hormonal factors and the diet We should therefore attempt to reduce katabolism by controlling infections, by administering suitable hormones, and by diet

Control of Infection

Infection is an important cause of death in renal failure, particularly acute renal failure Because of this I now follow Merrill (1953) and his team in isolating these patients and using a form of barrier nursing All who come into contact with them should wear masks and gowns In addition, I prescribe, as a routine, 0 5–1 0 mega-unit of penicillin per day Because of the virtual absence of renal function, this can be given as a single daily injection of a crystalline salt

In chronic renal failure these measures are impracticable, and one must rely on active treatment of infection when it develops, or, at most, provide penicillin cover and barrier nursing during any temporary exacerbations of the renal failure

The treatment of established infections presents certain special features in both acute and chronic renal failure Because of the renal failure, all antibiotics are excreted at a reduced rate This is not of any great importance in the case of penicillin, but with the other more toxic substances and the sulphonamides it may lead to danger- centrations in the body To avoid this, one must ter all antibiotics, other than penicillin, in reduced doses The mode of excretion of the sulphonamides all the common antibiotics, except penicillin, is glomerular filtration, a small proportion being reab by the tubules Thus the blood level is determined entirely by the dose and by the glomerular filtratio To maintain a satisfactory level one can adjust the with reference to the glomerular filtration rate—e g, an anuric patient with no appreciable filtration would give only a single loading dose, in a person 50% of normal filtration one would give the usual l dose, and then half the normal maintenance dose, and in a person with 25% of normal filtration one w give a quarter of the normal maintenance dose, so on

For the purpose of estimating dosage of anti as indeed for all clinical purposes, the blood urea l gives an adequate indication of glomerular filtration Fig 16 shows the approximate relation of the glom filtration-rate to the blood-urea level, at different lev of protein intake, in patients in nitrogen equilibrium

Hormonal Treatment

Masson et al (1949) found that nephrectomised an survived longer than controls when they were given anabolic hormone testosterone It is therefore cc practice to administer testosterone to anuric patient doses of 5–10 mg per day The indication for the of anabolic hormones in chronic renal failure azotæmia is less strong and, so far as I know, it has been tried

Protein-sparing Diet

As Borst (1948) points out, in all patients with failure, either acute or chronic, it is wise to r katabolism by providing a diet rich in carbohydrate possibly fat. The provision of adequate non pr calories pr the brea of tissue provide ene from prote katabolis In a no person mo protein sp can be with as l as 100 g carbohydra per day (C 1947), but in patients I certain that t is insuffi and that should aim an intake 300 g or per day anuric patie this large c hydrate has additi virtues de with on p

The ance of a fat diet is so certain Th is no doubt from the of Masson et (1949), that high-fat d increases

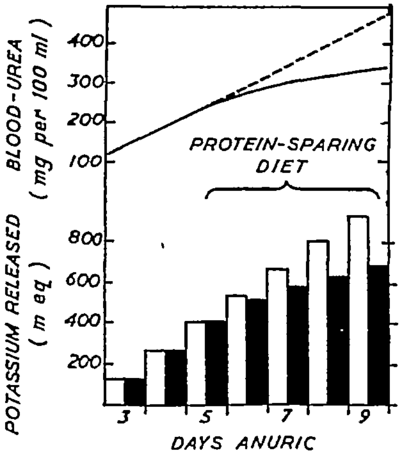

Fig 17—Effect of protein-sparing diet on rate of formation of urea and release of potassium from cells in anuria.

For the first five days of the illness the patient did not receive a protein sparing diet, and thereafter she received 2600 calories per day, as carbohydrate and fat As a result the rate of rise of the blood urea level fell By calculation from the blood urea levels and the body-weight we can estimate the quantity of potassium released from cells, here shown as a cumulative balance, each day s release being added to the previous day s total The blank histograms indicate the release that would have taken place if the patient had not received a protein sparing diet, and the solid histograms the actual quantity released Note how the protein sparing diet prevented the release of a considerable quantity of potassium urvival time of nephrectomised animals but this is robably a non specific effect of providing non protein alories Jockes, Lowe and I prescribed a high-carbo ydrate high fat diet for anuria (Bull et al 1949), but I m certain that a high-carbohydrate diet is sufficient I ave progressively reduced the fat-content of the diet nd sometimes leave it out altogether because diarrhœa levelops in some patients fed on some batches of eanut oil.

The effect of a high-carbohydrate diet in reducing atabolism in an anuric patient is shown in fig 17

ADJUSTMENT OF INTAKE

The substances whose intake it is most important to ontrol are water sodium potassium chloride and itrogen The rate of intake of these will vary according o whether the patient is in or out of normal balance or each individual substance and will also depend on he degree of impairment of renal control of excretion of each of them Thus, the regime prescribed will be in wo parts—first, correction of imbalance and secondly naintenance of balance One would always attempt to orrect the imbalances of as many substances as possible imultaneously but for convenience each substance is considered separately

Water

Underhydration —The most important abnormality of ater balance to recognise is extracellular underhydration, ith its attendant circulatory manifestations. This is sually combined with a greater or lesser degree of ellular underhydration A first approximation of the xtent of the water deficiency can be obtained clinically nd by measuring the specific gravity of the plasma y the method of Phillips et al (1950) For each 0 001 ise in the specific gravity of the plasma above 1·027 the atient lacks not less than 200 ml. of water (Phillips 1950) ome of this is extracellular water and some cellular o the appropriate ions for each compartment must ccompany the water either immediately or subse quently

It is usual to give only extracellular ions (Na Cl, and HCO$_3$) immediately and to delay the giving of intra ellular ions until later particularly potassium This is ecause an excess of intracellular ions in the extracellular pace is common in dehydration and time must be iven for them to adjust to a normal extracellular oncentration Thus, it is usually best to administer Na-containing fluids of a strength from a half to a third f the physiological This is done by administering ottles of 5% glucose between bottles of Na-containing uids The proportion of NaCl to either NaHCO$_3$ or a lactate (which is converted to NaHCO$_3$) administered ill depend on the state of acid base balance After this calculated quantity has been given a further linical assessment and an estimation of the specific ravity of the plasma should be made, and subsequent orrections ordered as necessary The volume of fluid alculated in this way may and should, be given rapidly o reduce the length of time the patient is in a state f circulatory insufficiency After the extracellular fluid olume has been corrected potassium may be given

Overhydration —Except in the anurias, the correction f overhydration is linked with that of salt retention will be considered later In anuric patients over ydration may be corrected by reducing the intake of uids to less than the insensible loss, and in some cases acupuncture Dialysis may also be used but is rarely cessary

Maintenance —The volume of fluid given will depend the ability of the kidney to excrete water and on rate of loss of fluid by routes other than the kidney ormal temperatures the rate of insensible loss of through the skin breath, and gut is about 800 ml.

A basic intake of 800 ml of fluid is therefore required in all patients In anuria, however a lower figure should be used—namely 600 ml, and not 1000 ml as Jockes, Lowe, and I prescribed previously (Bull et al. 1949) The reason for this reduction was given on p 733 —namely the production of water by the metabolism of body fat

To this basic intake should be added a volume of fluid to balance the volume of urine at optimal rates of urine flow The optimal rate of urine flow will vary with the type of renal lesion, but usually in patients with azotæmia it should be near the highest rate at which the kidney can excrete In a normal person a water diuresis causes a modest increase in rate of excretion of solutes and this persists in lesser degree in chronic renal failure Usually the greater the azotæmia the more one should attempt to achieve a high rate of urine flow, but the rate of fluid administration should never exceed the ability of the kidney to excrete water

In severely azotæmic patients (blood urea level above 100 mg per 100 ml) with chronic renal lesions, a satisfactory method of deciding on the optimal 'rate of' urine flow is to give a basic 800 ml of water, plus a volume of fluid equal to the previous day's volume of urine plus about 200 ml. The urine flow will increase and the procedure can be repeated until the urine flow is steady, or an inconveniently large intake of fluid is reached It is particularly important in these chronically azotæmic patients that the fluid intake should not fall A great many patients of this sort must have died as a result of ill advised restriction of fluids for a concentration test or for pyelography The main value of the former test is in the less severe renal lesions and I believe it should not be used in patients with a blood urea level above 100 mg per 100 ml

Sodium Intake

Correction of imbalance.—The removal of excess Na from the body is important in many conditions but I do not propose to deal with it here It is really the problem of the treatment of œdema

The correction of Na deficiency when it occurs as a part of extracellular underhydration has already been discussed, but a second type of Na deficiency without water lack, requires consideration This leads to cellular overhydration because water moves from the [illegible] cellular space to the cellular along an [illegible] (fig 5) To calculate the amount of Na necessary to correct the disturbance one may proceed as follows

Estimate the plasma Na level and subtract [illegible] *from* the normal serum Na level. This gives the deficiency in [illegible] Na per litre Superficially it seems that one would multiply the figure so obtained by the volume of the [illegible] fluid (about 15 litres) because Na is an [illegible] This quantity however is insufficient because [illegible] must be provided for the water which has moved [illegible] In practice one can assume that the deficiency [illegible] volume of distribution through total body water, [illegible] 30 litres (Black 1951) Therefore the [illegible]

(140 − x)30 m.eq of Na required, where x is the [illegible] level in m.eq per litre

Maintenance —In acute renal failure the [illegible] the maintenance dose of Na is simple [illegible] be 50–75 m.eq for each litre of urine [illegible] this figure was derived from a study [illegible] acute tubular necrosis (Bull et al [illegible]) [illegible] that the same figure is applicable in [illegible] renal failure, such as acute nephritis [illegible] and even in chronic renal lesions [illegible]

In chronic renal failure in [illegible] tion of Na is necessary [illegible] be less than 1 g per day [illegible]

In non œdematous patients [illegible] severe depletion of Na [illegible] for reasons given on p [illegible] non œdematous patients I always recommend a higher-than-normal intake of Na—200–300 m eq per day This is usually given as 3 g of $NaHCO_3$ + 2 g of NaCl, in addition to the salt ordinarily used in cooking and taken with the food If signs of œdema appear, the dose is reduced In special circumstances, particularly in the case of rarer tubular lesions without glomerular damage, different adjustments of intake may be required, and should be based on balance studies

Acid base Balance

Correction—As indicated above, a combination of clinical assessment and the determination of the plasma-HCO_3 level is usually sufficient to assess the degree of acid-base imbalance I also said that one can conveniently regard acidosis as a deficiency of base, and that this deficiency could be presumed to exist throughout total body-water Therefore, to calculate the amount of base needed to correct acidosis, one may use the formula

(27 − x)50, where x is the plasma CO_2 combining power in m eq per litre

This is best given as $NaHCO_3$ by mouth or as isotonic Na lactate intravenously

The *correction of alkalosis is slightly more complicated* in theory, but in practice the kidney can almost always make the necessary adjustments, provided the volume of extracellular fluid is normal and there is no deficiency of potassium One should therefore correct extracellular underhydration with solutions of Na chloride, and then the potassium deficiency The kidney will do the rest, even when it is severely damaged

Maintenance—In most patients with chronic renal failure there is a tendency to acidosis, because of the acid ash of most diets This should be prevented by prescribing extra alkali, usually $NaHCO_3$ For patients whose blood-urea level is above 100 mg per 100 ml I usually prescribe 2–5 g of $NaHCO_3$ per day In the rare cases of specific tubular defect much larger quantities will be required The dose may be adjusted by estimation of the plasma-HCO_3 level at intervals

Potassium

Correction of hyperpotassæmia—The particular danger of potassium retention lies in the fact that high concentrations of potassium in the extracellular fluid may cause cardiac arrest The high potassium level may be lowered either by causing the potassium to enter cells or by removing it from the body Alternatively, the toxic effect of a high potassium level may be counteracted by certain measures The most convenient method of dealing with hyperpotassæmia is to administer large quantities of glucose, which moves into the cells, taking with it potassium to form a glycogen-potassium complex This is the other reason (cf p 778) why a large intake of carbohydrate is desirable in the treatment of anuric patients The process may be hastened by simultaneous administration of insulin

Potassium may be removed from the body by dialysis, but in civilian practice it is rare for any form of dialysis to be necessary In warfare, as Meroney and Herndon (1954) have shown, the position is different Patients with gunshot wounds have large areas of necrotic muscle which release potassium at such a rate that conservative measures are not sufficiently rapid or effective Some form of dialysis is necessary, and the advantages of the artificial kidney over other forms of dialysis seem to make it the method of choice

Another less rapid method of removing potassium from the body is by feeding an ion exchange resin in the Na cycle (Evans et al 1953) The efficiency of the resin as a remover of potassium is about 1 m.eq per g in vivo in the case of the resin 'Zeo Karb 225' (Permutit Co)

It is also possible to reduce the toxic effect of hyper- mia by raising either the calcium or the Na level

Taking into consideration all these facts, Meroney Herndon (1954) describe a mixture containing calcium, and sodium which is useful for rapidly cor hyperpotassæmia

Correction of hypopotassæmia—Wherever possible is safest to administer potassium by mouth, even depleted patients Up to 10 g per day of KCl may given Where it is necessary to administer it intra-venously it may be given in concentrations of up 2 g per litre of infusion fluid, at a rate of not more 1 g per hour

It is a safe rule that potassium should never administered to anybody whose urine flow is less th 1 ml per minute

Maintenance—When the urine flow exceeds 1 ml minute, the quantities of potassium required to maint balance are not critical, except in a few circumstanc the most important of which is the early diuretic p of acute tubular necrosis Here it is best to allow urine flow to exceed 1 ml per minute for two days, allow the serum-potassium level to fall from the what high value which usually prevails in the phase Then 1–2 g of KCl per litre of urine passed be given

In rare tubular lesions and hormonal upsets b studies may be required to assess maintenance re ments for the ion

Nitrogen

The blood urea level is raised in most varieties of failure, but this in itself is of no consequence Th remains, however, the possibility that other and end-products of nitrogen metabolism are toxic, and their level rises parallel with that of urea For reason it is probably desirable to reduce the intake protein in patients with a low glomerular filtration There are, however, two other and more impo reasons for doing so

(1) Most protein foods contain potassium

(2) Urea, the most abundant end product of protein *down, accounts for a high proportion of the osmolarity* urine In most types of renal failure there is a cons osmotic diuresis (see pp 733 and 734), and this makes difficulty in maintaining water and electrolyte balance osmotic load may be reduced by diminishing the intake protein and therefore the quantity of urea to be excreted.

For these reasons a low-protein diet is desirable patients with marked azotæmia As a temporary m a protein-free diet may be given in acute renal failure in exacerbations of chronic failure, but for m in chronic failure one must always provide e protein *to take the place of the endogenous* inevitably broken down , 30 g is usually sufficient this purpose When the blood-urea level is be normal and about 70 mg per 100 ml , I usually pres a normal intake of protein of about 70 g daily the blood-urea level is between 70 mg and 120 I give about 45 g daily, and when it is above 120 the minimum of 30 g daily

Symptomatic Treatment

Anæmia—Severe degrees of anæmia should never allowed *to persist* in patients with renal failure, b they induce a mild degree of circulatory renal in ciency The hæmoglobin should be kept above 65–70 by means of blood-transfusions In certain circums (e g , in anuric patients) packed red cells should be g The usual hæmatinics, such as iron, vitamin B_{12}, f acid, and liver, have no effect on this type of an but it is said that cobaltous chloride 90–200 mg may be effective (Gardner 1953) I have no exper of this form of treatment

Vomiting—Nausea and vomiting develop in uræmic states One should first attempt to de its chemical basis—e g , cellular overhydrat

orrect it, but sometimes no obvious chemical cause can
e found Then one may use chlorpromazine (Friend
nd Cummins 1953) in doses of 25–50 mg three times
aily by injection or by mouth I have found it
oderately effective

Vomiting if persistent, makes for considerable diffi
iculties in maintaining the balance of fluids and electro
rtes. In these circumstances I have often used a
'Polythene' tube 1 0–1 5 mm in diameter passed through
he antecubital vein into the superior vena cava or
hrough the femoral vein into the inferior vena cava
hrough this tube one can administer even very concen
ated solutions such as 50% glucose by continuous
ip for long periods One man who had a severe
dominal injury, was fed thus for 56 days without
y oral intake

Stomatitis, another common complication in the gastro
estinal tract in severe renal failure is best treated
y frequent mouth washes

Diarrhœa is sometimes very troublesome and may
ove fatal Where there is a possibility that it is
luced by the diet—as sometimes happens with some
patches of peanut oil in treating anuric patients—one
ay stop oral feeding and administer the necessary
uid carbohydrate, and electrolytes intravenously In
ss severe cases I administer 1 g of streptomycin twice
aily by mouth in the hope that a change of intestinal
ora will allow the diarrhœa to settle.

Epileptiform convulsions are most often due to a
ecognisable cause—e.g hypertension and cellular over
ydration Where no cause can be found or where the
use cannot be removed barbiturates or paraldehyde
y be used in the usual dosage The same drugs may
used for restlessness insomnia and noisy delirium
t again one should seek a cause and treat it rather
n rely on symptomatic treatment

ypertension —Although not strictly a part of the
tment of uræmia the treatment of hypertension in
al failure needs to be considered here Because of
danger of further renal failure as a result of arteriolo
rosis, I usually attempt to lower hypertension in
ents with chronic renal failure when the diastolic
d pressure exceeds 110–115 mm Hg I use hexa
onium and rauwolfia serpentina for the purpose but
minister the former in particular with great caution
ne patient with severe renal failure developed a
eneralised muscular paresis which lasted nearly a week
fter a single test dose of 10 mg of hexamethonium
now usually start with a dose of 1 mg

Conclusions

I have tried to show that renal failure gives rise to
ny clinical pictures—the uræmias. These uræmias are
t an inevitable consequence of renal failure but result
m imbalance between the rate of loss and the rate of
ake or of production in the body of certain chemical
stances. Some at least can be prevented by adjustment
f the diet

CHLORPROMAZINE IN OBSESSIVE-COMPULSIVE AND ALLIED DISORDERS

W H TRETHOWAN
M.B Camb M R C.P D P.M
SENIOR LECTURER IN PSYCHIATRY IN THE UNIVERSITY OF
MANCHESTER

P A. L SCOTT
M B B.Sc St And D.P M
PSYCHIATRIC REGISTRAR, MANCHESTER ROYAL INFIRMARY

REPORTS of the psychiatric use of chlorpromazine in patients are now fairly numerous Favourable claims chiefly of the control of agitation and excitement in patients with various psychoses, came initially from the Continent (Hamon et al. 1952 Delay and Deniker 1952 Delay et al 1953 Arnold et al 1953, Deschamps and Cadoret 1953) At Basle in November, 1953, 893 cases so treated were discussed (Staehelin 1954) these included cases of depression (Kielholz 1954) and a considerable number of schizophrenics (Labhardt 1954) in many of whom substantial improvement was reported.

From England the number of reports has been less. The findings (Anton Stephens 1954 Garmany et al 1954 Lancaster and Jones 1954 Elkes and Elkes 1954) though favourable are less conclusive than those of the Continental workers

Although chlorpromazine is valuable in the treatment of severer forms of mental disorder among inpatients its efficacy in the treatment of outpatients with less overt mental disturbances is not so well established Garmany et al (1954) who investigated the effects of chlorpromazine in 29 psychoneurotic patients found that all patients in whom tension was prominent improved but they could not confirm the relief from obsessional symptoms claimed by Sigwald and Bouttier (1953)

However, since patients with intractable obsessive-compulsive symptoms form a substantial proportion of those attending psychiatric outpatient clinics and demand much time and attention any possibility of obtaining some relief in these cases should be explored. This was the main purpose of the present investigation

In addition the impression has been gained that chlorpromazine is at present fairly widely used not only in psychiatric clinics and hospitals but also by general practitioners The fact that this treatment is not apparently devoid of risk argues the need for a clearer understanding of its effects and the indications for its use

Clinical Material

75 outpatients (36 men and 39 women) were originally selected for a therapeutic trial of chlorpromazine Owing to irregular attendance (5 cases) intercurrent physical illness (6 cases) and complications arising from the treatment (5 cases) 16 patients did not complete a

* Mild episodic symptoms are excluded

course of sufficient length or regularity to permit valid conclusions to be drawn Further reference to some of these will be made when side effects are discussed The clinical assessment of the results is therefore confined to 59 patients (30 men and 29 women)

Only those who had psychoneuroses or personality disorders with some symptoms of an obsessive or compulsive kind were selected

Age—The patients were aged 20–57 (average 35), 32 (54%) were aged 25–35

Duration of symptoms—In only 11 patients (18%) was the total duration of symptoms relatively short—from 4 months to 4 years In 18 (30%) nervous symptoms had been present, either continuously or with occasional remissions, ever since childhood In another 9 (15%) symptoms appeared during adolescence (i e, at the age of 12–15) and persisted from that time In the remaining 21 patients (36%), whose illness did not begin until after the age of 18, this was also of long duration (up to 26 years), with periodic variations in intensity

Diagnosis and classification—Diagnostic subdivision of cases of this kind is at present somewhat controversial In view of this more attention was paid, in comparing the patients, to the presence, absence, severity, and persistence of symptoms than to formal diagnosis (table I) However, some arbitrary divisions are possible 6 patients only exhibited the classical obsessive compulsive neurosis, 11 had symptoms predominantly of a phobic kind (e g, fear of crowds and of going out alone), 11 others were constantly preoccupied with morbid thoughts or impulses (e g, aggressive urges towards self or others and obsessions of jealousy), and in 13 the presenting picture was mainly hypochondriacal The remainder showed mixed clinical conditions, usually states of tension, irritability, anxiety, and secondary depression coloured by obsessive-compulsive features and accompanied by somatic complaints, though almost every known variant was present, including hysterical features in 5 cases

Degree of disability—This was assessed both before and after treatment by the use of an 11 point scale, positioning on which depended not only on the number and severity of symptoms but also on each patient's estimated working capacity and effectiveness as a social ble II) Initially 35 patients (59%) were placed th and 5th points of the scale and thus could be considered as moderately incapacitated by symp The positioning of the remainder appeared to follo normal distribution around this peak.

Method of Investigation

(1) The patients were observed for 7–18 weeks—in two thirds of the cases for 12–14 weeks All patients attended weekly for 7–15 weeks, after wh some were seen at intervals of 2, 3, or 4 weeks

(2) All the patients received both chlorpromazine an inert, though apparently identical, placebo, b being taken by mouth No patient knew which being given or that a placebo was being used at all.

(3) In addition more than half the patients had a without treatment at some time during the course.

(4) The course of treatment was controlled by investigator only The other remained ignorant only of what was being given but also of alterations dosage

(5) 31 patients began treatment with ch and 28 with the placebo This was determined by cha (odd or even number of letters in surname) the course of treatment was to plan, modified in a cases by individual response

(6) During the initial period (7–18 weeks) four dif courses of treatment were used

(*a*) Chlorpromazine for 4–5 weeks, placebo for 1–3 w *and chlorpromazine for 2–13 weeks (14 patients)*

(*b*) Chlorpromazine for 4–6 weeks, placebo for 1–2 and no treatment for 1 week (17 patients)

(*c*) Placebo for 2–3 weeks, chlorpromazine for 4–6 and placebo for 1–3 weeks (13 patients)

(*d*) Placebo for 2–3 weeks, chlorpromazine for 4–7 and no treatment for 1 week (15 patients)

(7) After the initial period 42 patients received fur treatment with chlorpromazine alone (29 cases) or both chlorpromazine and placebo alternately (12 or with placebo alone (1 case)

(8) Initially chlorpromazine 50–75 mg was pres daily The daily dose was increased in the second to 100 mg and in the third and subsequent week 150 or 200 mg, at which level it was maintained

(9) *At every visit all the patients were seen se* by each observer, both of whom made an indepen

TABLE II—CLINICAL RATING SCALE OF DEGREE OF DIS

	No of patie	
	Before treatment	*Af tr*
(1) Ill enough to need hospital admission	0	3
(2) *Intermediate between 1 and 3**	0	1
(3) Severely incapacitated—e g unable to work/perform domestic duties unable to go out unaccompanied fully preoccupied with obsessions, compulsive rituals phobias, &c severe continuous tension, anxiety or depression	2	3
(4) Intermediate	8	6
(5) Moderately incapacitated—e g working irregularly or continuously with difficulty domestically and socially ineffective variably severely preoccupied with obsessions &c moderate continuous/severe episodic tension anxiety or depression	18	7
(6) Intermediate	17	7
(7) Mildly incapacitated—e g able to work/do domestic duties social activity not completely satisfactory obsessions &c, only occasionally prominent mild continuous/moderate episodic tension anxiety or depression	10	1
(8) Intermediate	4	11
(9) Slight incapacity only—e g able to work with some efficiency no impairment of social or domestic life obsessions, &c though episodically present largely in background mild episodic tension, anxiety or depression	0	5
(10) Intermediate	0	3
(11) No apparent disability whatsoever	0	1

* Those placed in intermediate categories either varied bet showed some features of, both neighbouring groups

assessment one using the method of the ordinary psychiatric interview, the other a questionnaire devised to record and compare statistically the changes in number and severity of each patient's main symptoms

(10) The weight and blood pressure of every patient were recorded at each attendance

Results

A significant response to chlorpromazine compared with the response to the placebo was observed in 27 (46%) patients In the other 32 (54%) there was no significant difference in the responses to chlorpromazine and to the placebo, though in some cases changes in condition took place (table III)

Responses to Chlorpromazine

27 patients responded to the first course of chlorpromazine 14 of them began treatment with the acebo for 2 weeks, during which there was no appreciable change In 2 other patients this period was extended 3 weeks because of a slight transient initial improvement, presumably due to suggestion, which disappeared by the end of the 3rd week After this all 14 were treated with chlorpromazine The remaining 13 patients were given chlorpromazine from the start

After 4–6 weeks on chlorpromazine 21 patients were given the placebo again while the remaining 6 patients were left without treatment for a week.

All 27 patients had a return of symptoms usually within 3–5 days of withdrawal of the chlorpromazine The severity of the relapse varied the condition of most patients returning to the pre treatment level 6 patients however became considerably worse than before 3 of these developed a state of agitated depression of such severity that admission to hospital became necessary

Although after relapse all 27 patients were again given chlorpromazine 10 now did not respond and in the remaining 17 the response was on the whole less satisfactory than that originally observed Although the 6 patients who relapsed most severely were all among those who originally responded best, only 2 showed any response to the second course of chlorpromazine in 1 one was the response as good as before in the other it was slight In the remaining 4 patients the exacerbation of symptoms persisted unchanged

TABLE III—RESPONSES TO CHLORPROMAZINE

	Men	Women	Total	
Positive response to chlorpromazine compared with response to placebo.				
(a) Response to 1st course of chlorpromazine with relapse when this was withdrawn				
Moderate to good response	10	9	19	
Slight response only	4	4	8	
Total	14	13	27	(46%)
(b) Response to 2nd course of chlorpromazine in those responding to 1st course and relapsing after this was withdrawn				
Moderate to good response	5	6	11	
Slight response only	2	4	6	
Total	7	10	17	(29%)
(c) Non responsive to 2nd course following relapse after withdrawal of 1st course	7	3	10	(17%)
Negative response to 1st or subsequent course of chlorpromazine compared with response to placebo				
(a) Equal improvement with chlorpromazine and placebo with no relapse when chlorpromazine was withdrawn:				
Moderate to good improvement	4	2	6	
Slight improvement only	3	1	4	
Total	7	3	10	(17%)
(b) No essential change on either chlorpromazine or placebo	9	11	20	(34%)
(c) Worse		2	2	(3%)
Total	16	16	32	(54%)

TABLE IV—CHANGES IN CLINICAL CONDITION OF ALL PATIENTS AT END COMPARED WITH BEGINNING OF INVESTIGATION AND TREATMENT

Change	No of points gained or lost on rating scale	Men	Women	Total

Moderately	−2	3	2	5	
	−3	1		1	
Much worse	−4	1		1	
Total		8	4	12	(20%)

* See table II

No Response to Chlorpromazine

32 patients showed no response to chlorpromazine The condition of 20 remained essentially unchanged throughout that of 2 others became rather worse

In 10 patients some improvement took place, in 6 to a considerable degree None of these patients relapsed when chlorpromazine was withdrawn or when the placebo was again substituted all maintaining their improvement whatever plan of treatment was followed Although there was no initial change in the condition of 3 of these patients who started treatment with two weeks on the placebo the improvement later observed both in these and in the 7 other patients who were put on chlorpromazine from the start could not be definitely ascribed to the chlorpromazine but was more probably due either to spontaneous remission or to suggestion

The final condition of all the patients at the end, compared with the beginning of the investigation is summarised in table IV

Response of Individual Symptoms

(1) The following symptoms showed the most response to chlorpromazine compared with the response to placebo (differences significant at $p=0{\cdot}02$ or higher): loss of appetite anxiety and tension, irritability hypochondriacal symptoms aggressive urges towards self or others, lack of concentration and difficulty in getting to sleep

(2) Symptoms which responded to some extent to chlorpromazine but not significantly so compared with the response to placebo were palpitations, sweating, aches and pains trembling phobias indecision intellectual rumination self-consciousness depression, ego disorders, waking at night, excessive self-criticism, stammer and tinnitus

(3) The following symptoms showed no response to chlorpromazine compared with that to placebo: headaches digestive disturbances, compulsive rituals, writer's cramp and facial tic

(4) Symptoms which became significantly worse when the placebo was substituted for chlorpromazine, compared with the period on placebo preceding the first course of chlorpromazine, were anxiety and tension, depression palpitations and sweating

Changes in Weight

47 patients (80%) gained weight during treatment—up to $16^1/_4$ lb In 2 patients the weight remained stationary while 9 lost up to $6^3/_4$ lb 1 other obese overweight patient lost $11^1/_4$ lb The average weight change of the whole group was +4 lb

Though there was no clear relationship between gain in weight and degree of clinical improvement those whose symptoms responded to chlorpromazine gained

TABLE V—COMPLICATIONS AND SIDE EFFECTS

	No of patients	*Approx proportion (%) of total*
Drowsiness	35	50
Transient or postural dizziness	9	13
Vivid dreams or nightmares	8	11 5
Skin rashes	7	10
Constipation	7	10
Pyrexial attacks	6	8 5
Thirst or dryness of mouth	5	7
Abdominal discomfort	3	4
Jaundice	3	4
Hypnagogic hallucinations	2	3
No definite side effects	13	19

* The incidence of side-effects is assessed in relation to 70 of the original 75 patients The other 5 did not attend for more than two consecutive weeks and received placebo only

more (average $4^1/_2$ lb) than in those who showed no positive response (average $2^3/_4$ lb)

Blood pressure

In 55 patients (93%) a transient fall in systolic blood-pressure, up to 60 mm Hg (average 19 mm Hg), took [illegible] under treatment with chlorpromazine A fall in [illegible] pressure, up to 30 mm Hg (average 19 mm Hg), was observed in 45 patients (76%) The remaining patients showed some variations but little change in relation to treatment The blood-pressure of most patients though somewhat lower at the end, compared [illegible] the beginning, of the investigation was not significantly so

Complications and Side effects (table v)

Jaundice, the most serious complication, developed in [illegible] patients (1 woman and 2 men) after 9, 18, and 19 days' treatment, during which about 1075, 2200, and 2450 mg of chlorpromazine had been given In all 3 the attack [illegible] 2–3 weeks and clinically resembled a mild attack of infective hepatitis None had had a previous attack of jaundice, though this was recorded in the history of [illegible] of the 70 patients

Skin rashes, although observed in 7 patients, did not constitute a serious bar to further treatment Treatment was stopped in 1 case largely because the patient found that she was pregnant, which seemed to promote a spontaneous remission of symptoms The rashes were of various types, erythematous, maculopapular, and urticarial, preceded and accompanied by itching The distribution was usually widespread, the neck, upper arms, shoulders, chest, and thighs being mainly affected One patient, a sufferer from ichthyosis, developed an outbreak of eczema on the fingers Either reduction of dosage or temporary cessation of treatment effected a speedy resolution of all these skin reactions

At least 6 patients developed *pyrexia* during treatment It usually lasted 48 hours, the main symptoms being sweating, severe headache, nausea, epigastric discomfort, and aching in the limbs and back The number may have been higher, but, since the attacks were not actually observed but described retrospectively by the patients at their weekly visits, and because of a concurrent widespread outbreak of upper respiratory infection, the symptoms proved difficult to assess Rhinitis, sore throat, and other indications of upper respiratory infection were, however, absent in these cases In addition 2 patients described vivid hypnagogic hallucinations in association with the attack In all cases treatment was continued without prolongation of the symptoms.

Other *minor side effects* complained of included transient or postural dizziness probably related to a fall or to increased lability of blood-pressure, thirst, abdominal discomfort, and constipation 8 patients commented spontaneously on the occurrence of vivid dreams or nightmares Some drowsiness developed initially in at least half the patients, and recurred in some cases when the dosage was raised, but in either event passed off [illegible] within a few days 1 patient, however, com[illegible] severe drowsiness and discontinued attendance [illegible] reason

Discussion

Although from the therapeutic point of view the results of the present investigation are not impres they might have been better if a different plan of tr ment had been used 27 of the patients appeared receive some benefit from chlorpromazine in the stages, but only 19 of these improved to any degree

The return of symptoms after sudden withdrawal chlorpromazine in all these cases, but not in the 10 patients who appeared to improve spontaneously, ag closely with the findings of Azima and Ogle (1954), observed similar relapses in 70% of their patients

Moreover, after the withdrawal of chlorpro there was significantly less response to a further co In view of this and the fact that the condition of patients in relapse was more severe than their o condition, it cannot be overemphasised that, where satisfactory response appears to be produced, trea should not be precipitately withdrawn but should be tinued with, perhaps, a gradual reduction of dosage la

The *occurrence of jaundice in 3 of 70* patients closely with the recorded incidence of some investigators (Azima and Ogle 1954, Elkes and 1954, Lancaster and Jones 1954) and almost exac with that of Lehmann and Hanrahan (1954), observed this complication in 3 of 71 cases The c needs further elucidation, but since 1 of the patients had been in close contact with a case of infe hepatitis 6–8 weeks earlier, it is of interest that A and Ogle, who observed this complication in 5 of cases, recorded a concurrence of infective hepatitis the community The fact that jaundice developed all 3 cases within a short time, after a relatively s dosage had been given, suggests either idiosyncrasy some other predisposition

Apart from jaundice, which indicates a need caution in the use of chlorpromazine, other side-effe are common and may be unpleasant

The incidence of pyrexia was lower in the present seri than in the 10% of patients treated by Garmany et (1954), but a possible reason for this has been indicat The *development of hypnagogic hallucinations* in patients is believed to be a new observation, but An Stephens (1954) has already remarked that dreams increase

Despite difficulties chlorpromazine is clearly of v in the treatment of neurotic disorders in which and tension are prominent, this was also the opinion Garmany and other workers Furthermore it appe that chlorpromazine may safely be used to treat patients, providing adequate supervision is ma and the patients are instructed to report immedia any unusual symptoms Although a previous history jaundice, unless recent, is not necessarily a co indication, it seems unwise to give chlorpromazine patients suspected of hepatic dysfunction

Compared with the widely used combination of d amphetamine and amylobarbitone, which, alth merely a euphoriant, has the advantage of being free from side effects, chlorpromazine appears to rather more effective and specific in controlling sym of anxiety and tension, in addition it produces increase in appetite and weight.

In the control of classical obsessive comp symptoms chlorpromazine has proved disap Though some phobic symptoms and intellectual tion seemed to be partially relieved, no lessening of incidence and severity of compulsive rituals was ob The only compulsive symptoms responding signific to chlorpromazine were aggressive urges towards self others and obsessive hypochondriacal ideas

In the selection of patients for treatment with ch promazine the presence of anxiety, tension, and ce ther symptoms provides a more reliable criterion than oes the degree of conformity with any theoretical or ebatable diagnostic category

Summary

The effects of chlorpromazine on 59 outpatients suf ring from neurotic disorders with obsessive-compulsive atures were investigated

All the patients received, at different times both hlorpromazine and an apparently identical inert placebo

In those who responded sudden withdrawal of chlor romazine produced a relapse. After this some did not espond when chlorpromazine was again given The nadvisability of sudden withdrawal is emphasised

Those patients in whom tension and anxiety were rominent did best Little relief of obsessive-compulsive ymptoms apart from aggressive urges and hypo hondriacal ideas was obtained

The frequency of side-effects was assessed in 70 atients Although common none were serious except aundice which occurred in 3 cases

We wish to thank Prof E W Anderson for his advice and ssistance

RADIOLOGY IN THE MANAGEMENT OF ANTERIOR PLACENTA PRÆVIA

J K RUSSELL
M.D Aberd M.R C O G
LECTURER IN OBSTETRICS AND GYNÆCOLOGY,
UNIVERSITY OF DURHAM

C K WARRICK
M.B Lond. F R C.S.E., F.F.R
ASSISTANT RADIOLOGIST ROYAL VICTORIA INFIRMARY
NEWCASTLE UPON TYNE

rom King's College Durham University and the Princess Mary Maternity Hospital Newcastle upon Tyne

As a result of the renewed interest in radiological ocalisation of the placental site for which the work of Reid (1949 1951 1952) was principally responsible it is ow widely appreciated that radiology has brought a new ccuracy to the diagnosis of placenta prævia

Techniques have been described by Whitehead (1953) and Iartley (1954) and modifications of these and other methods re in use in many centres. Stallworthy (1951) and Dawson nd Mitchell (1954) have described the clinical application of adiology in cases of antepartum hæmorrhage and it has een shown that many patients who would otherwise have ad to spend weeks in hospital can now be discharged safely their homes In other cases placenta prævia has been orrectly diagnosed before any bleeding.

We draw attention here to the precision which radiology an give to the management of anterior placenta prævia he point is illustrated in the following two case reports

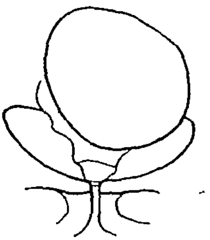

Fig. 1

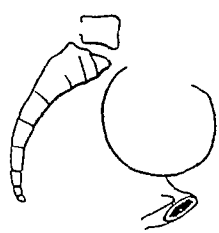

Fig. 2.

Fig 1—Case 1 : anteroposterior position showing displacement of fœtal head to the left.

Fig 2—Case 1 : lateral erect position showing 2 cm. separation of fœtal head from pubis.

Case reports

Case 1 —A woman was admitted to the Princess Mary aternity Hospital as an emergency case on July 25 1953 when 30 weeks pregnant a brisk vaginal hæmorrhage had taken place a few hours before admission.

On admission the patient's general condition was satisfactory and she was kept at rest in bed for a week after which a radiological examination was made (figs. 1 and 2)

Radiologist's Report (Aug 1 1953) — Single fœtus cephalic presentation Occiput to the left The head is not engaged and is placed asymmetrically in relation to the pelvic inlet in the anteroposterior film In the lateral projection the head is separated from the sacral promontory by 1 0 cm and from the symphysis pubis by 2·0 cm.* These measurements, combined with the displacement of the fœtal head in the anteroposterior film and the situation of the soft-tissue shadow indicate the presence of right anterior placenta prævia.'

Subsequent History—Four days after this report was received arrangements were made for the patient to be examined in the theatre and the pædiatrician was warned that if a cæsarean section proved necessary the placenta might be damaged in the course of the operation and the baby require transfusion. Vaginal examination revealed that the internal cervical os was covered by placental tissue, and an immediate lower segment cæsarean section was done The placenta as expected, was found under the uterine incision. Guided by the radiologist's report that the placenta was lying mainly to the right the operator passed his hand towards the left side separating the placenta from the uterine wall and was able to circumvent it without undue difficulty The baby was delivered and the cord clamped without delay Although the placental substance was disrupted no fœtal vessel was damaged. The baby made excellent progress.

Case 2 —A primigravida aged 31 was admitted to the Princess Mary Maternity Hospital as an emergency case of antepartum hæmorrhage on May 4 1954 She had been married for 10 years and had never taken precautions against pregnancy She was 34 weeks pregnant on admission, and the clinical features suggested placenta prævia. She was examined radiologically on May 17, 1954 (figs 3 and 4)

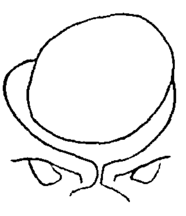

Fig 3

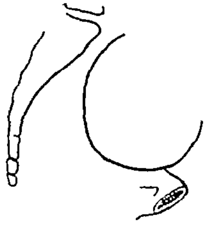

Fig. 4.

Fig 3—Case 2 : semi-erect anteroposterior position showing slight displacement of fœtal head to the left.

Fig 4—Case 2 : lateral erect position showing 2 cm. separation of fœtal head from pubis.

---

* All radiological measurements have been corrected for magnification.

Radiologist's Report — "Single fœtus, cephalic presentation, occiput to right side The uterine shadow is thickened anteriorly The fœtal head is separated by 1 5 cm from the sacral promontory and 2 0 cm from the symphysis pubis There is slight asymmetry in the semi erect anteroposterior radiograph The appearances indicate the presence of right anterior placenta prævia "

Subsequent History —The patient remained in hospital, and small vaginal hæmorrhages occurred on two or three occasions At the 38th week the patient was examined in the theatre, and the pædiatrician was warned about the possibility of placental damage at operation The placental edge was felt anteriorly 3/4 inch from the cervical os, the examination caused a brief hæmorrhage, and in view of the long period of infertility it was decided to do a cæsarean section The placenta covered the anterior wall of the lower uterine segment, but in view of the radiologist's report the operator was again able to circumvent the placenta without difficulty The placenta was partially disrupted, but no fœtal vessel was pierced The baby made excellent progress

Discussion

When the placenta is situated anteriorly in the lower uterine segment, cæsarean section carries a particular risk for the fœtus, blood loss from the fœtal circulation, the result of laceration of the placenta, may place the life of the child in jeopardy The extent of this hazard and the manner in which it might best be handled were studied carefully in the Princess Mary Maternity Hospital by Neligan and Russell (1954) Between January, 1951, and March, 1953, 45 lower-segment cæsarean sections were done for placenta prævia, and the placenta was found in the incision 20 times, in 11 instances there was significant damage to the fœtal circulation, and 7 babies were transfused This injury was the direct cause of 1 neonatal death

For the past two years the obstetric staff of the hospital have paid special attention to operative technique in these cases During this period 35 cæsarean sections have been done for placenta prævia, the placenta was found in the uterine incision in 15 of the cases In no instance has there been significant damage to the fœtal circulation, and none of the babies has required transfusion

In some measure the improvement in results has been due to the increased use in the hospital of radiological localisation of the placenta In 5 of the 15 cases with an anterior placenta prævia the obstetric staff were forewarned of its site by the radiologist, details of 2 cases have been given above When a severe degree of anterior placenta prævia is noted by the radiologist, we ensure that the case is managed personally by a senior member of the staff thoroughly conversant with the operative technique required to avoid damaging the placenta Our pædiatric colleagues are also advised about the possibility of damage to the fœtal circulation In the 2 cases reported above the operator received valuable information from the radiologist about the best way of circumventing the placenta without damaging fœtal vessels

In our experience radiology is making a significant contribution to the management of this important type of placenta prævia

Summary

Localisation of the placenta by radiography is now used in many centres in this country, but the extent of the contribution which the method can make to the management of placenta prævia has yet to be determined

When the placenta is situated anteriorly, there is an increased risk of damage to the fœtal circulation in cases of cæsarean section In the Princess Mary Maternity Hospital radiology is adding a new precision to the management of this important type of placenta prævia

We are grateful to Prof Harvey Evers for permission to details of cases admitted to the Princess Mary Hospital under his care The tracings of the radiographs were made by the department of pho of the University of Durham

BRONCHIAL CARCINOMA

SURVEY OF 317 PATIENTS

J R BIGNALL
M.A, M D Camb, M R C P

SENIOR LECTURER, INSTITUTE OF DISEASES OF THE
BROMPTON HOSPITAL, RESEARCH ASSISTANT, INSTITUTE
CANCER RESEARCH, ROYAL MARSDEN HOSPITAL

THE Brompton Hospital and the Royal M Hospital are specialised hospitals, the former is cerned with diseases of the chest and the latter with types of cancer Both draw their patients predomin from London and the southern counties, but ne serves a particular area Many patients are first elsewhere and are sent for bronchoscopy, surgical ment, radiotherapy, or a second opinion Some directly from their general practitioner, and a few abroad The story of the patients with bro carcinoma at these hospitals does not therefore pr the experience of all such patients throughout country

The hospitals are linked by a joint consultative cl for the study of the disease, and in particular its treat ment by radiotherapy (Brooks et al 1951) D 1951, 317 patients with bronchial carcinoma atter the hospitals All but 1 have been followed for two ye from their first attendance 1 patient left the co soon after radiotherapy and is considered to have d This report describes the history of these patients, far as it has been discovered by observation at joint consultative clinic, and from hospital records reports from general practitioners

Validity of the Diagnosis

The diagnosis was based on histological evidence 199 (62%) of the 317 cases The tissue was obta by bronchial biopsy in 91, removal of the tumour 53 and of a metastasis in 27, necropsy in 16, of sputum in 11, and drill biopsy in 1

There was no histological confirmation in 118 (cases In 10 cases there was macroscopic evidence necropsy but no further examination was made patients were found to have inoperable tumours thoracotomy There was clinical or radiographic evi of metastases in 48, and bronchoscopic evidence of tumour in 13 and of mediastinal metastases in In 20 there were other suggestive broncho abnormalities although no tumour was seen In 8 (2 5%), therefore, did the diagnosis rest purely clinical and radiographic evidence of pulmon abnormalities

Certain diagnosis is difficult Even at necropsy diagnosis without histological examination may wrong, there are 2 examples of this event in the rec of the joint consultative clinic (Smithers 1953) It se reasonably probable, however, that all but a very of the 317 patients did have a bronchial carcinoma

Composition of the Group

The group contained a high proportion of pa between 50 and 60 years of age and a low pr ver 70 The age distribution of patients with bronchial arcinoma throughout the population is not known stimates based on death certificates are probably inaccurate owing to the difficulty of diagnosis without investigation in hospital. It is likely that fewer old eople will be fully investigated; and the proportion ver 70 may therefore be falsified by wrong diagnoses Death certificates during 1951 showed that 20% of the 3 247 recorded cases were in patients over 70 (Registrar General 1951) Hospital necropsy records may be no more accurate, for cases are selected both for admission o the particular hospitals and for examination after eath A series of 741 necropsies in several London hospitals during 1948–52 contained 16% over 70 Galuzzi and Payne 1955) The proportion of the present group over 70 (5%) is considerably lower than either of the other estimates This is not unexpected at two pecial hospitals with full facilities for surgical treatment and radiotherapy

There was also a very low proportion of women over 70 (6%) compared with the proportions in the necropsy and death-certificate records (24%) The numbers involved are very small During 1952 slightly more patients with bronchial carcinoma were seen The proportion of those between 50 and 60 was lower and over 70 higher, than in the previous year There was also a higher proportion of older women However the proportion in the two years combined is still much lower than the estimate from death certificates and necropsies

The frequency of the main histological types differs from that in necropsy reports Necropsy estimates cannot be accepted as the true distribution for they may well be biased in favour of the more malignant growths hose causing death before diagnosis or producing a rapidly fatal illness. On the other hand estimates from hospital records may contain too few malignant tumours. Histological examination is less likely in patients who already have extrathoracic metastases or are clearly beyond hope of effective treatment Certainly the frequency of overt metastases when the patients first attended hospital was twice as great in the present series in those without histological confirmation (40%) as in those with it (20%) Both hospital and necropsy records suggest that the proportion of undifferentiated tumours is a little greater in women than in men. In the present series there were ten times as many men as women whereas the ratio in 1951 according to death certificates was approximately 5 to 1 Registrar-General 1951) In necropsy records (Bryson and Spencer 1951 Galuzzi and Payne 1955) undifferentiated tumours make up about two thirds of the total and squamous tumours a fifth but in the present group and in a larger one also drawn mainly from special hospitals (Doll and Hill 1952) undifferentiated tumours were reported in only a little over a third and squamous in approximately a half of the patients in whom the type was known It is impossible to find out how much the pattern of histological types in the whole group differs from that of the sample examined or whether estimates from hospital records are closer to the real frequency than those from necropsies Such comparisons of histological types are very uncertain for classification of the tumours depends on the particular portion examined as well as on the pathologist's interpretation of the appearances In the present series, for instance lthough the same pathologist reported on almost all the sections the type reported from the bronchial biopsy differed from that reported from the whole tumour or a metastasis in 9 of the 114 cases in which both examinations were done

It seems reasonable to conclude that the present series compared with all patients with lung cancer ontains fewer with undifferentiated tumours as well s fewer women and old people

History Before Going to Hospital

It is often difficult for the patient to remember when his symptoms began, particularly when the first indication of ill health was merely an unaccustomed tiredness, shortness of breath, or change in a long-standing cough

The estimate of duration of illness is, therefore frequently only very approximate In the few patients who had no symptoms at all the illness is considered to have begun at the time the radiographic abnormalities were found Owing to the method by which the patients were referred to the hospitals a long history of symptoms at the first attendance does not necessarily indicate delay in diagnosis

A little over a fifth had had symptoms or signs for less than two months and half for less than four, but 1 in 10 had been ill for more than a year The duration of symptoms does not measure the age of the cancer For instance 10 had no symptoms at all although the lesion was large enough to be discovered by radiography; whereas in 5 the first warning of ill health was caused by metastases (hoarseness 3 dysphagia 1 obstruction of the superior vena cava 1) Metastases indicate an advanced stage of the disease, but not necessarily a late one in terms of duration of ill health As expected, the incidence of metastases when the patients were first seen at the hospitals was less in those with shorter histories; nevertheless it was nearly 9% in those with evidence of disease for less than a month It rose to 50% in patients with five months' history On the other hand only 12% of those seen after a year had metastases; presumably this was because of the inherently slow growth and spread of the tumour, or because of the appearance of symptoms at an unusually early stage in its development

History after Coming to Hospital

Treatment

Almost a third (28%) of the patients had clinical or radiographic evidence of metastases when first seen Metastases were found in a further 4% at subsequent examinations and in 9% at bronchoscopy Among the 317 cases thoracotomy was undertaken as follows

- *Exploratory thoracotomy* 81 (25%)
  - Resection 57 (18%)
  - Resection impossible 24 (7%)
- *No thoracotomy* 236 (75%)
  - Metastases 130 (41%)
  - Position of primary 34 (11%)
  - Poor general condition 21 (7%)
  - Poor respiratory function 20 (6%)
  - Refusal 5 (2%)
  - Other reasons 26 (8%)

Thus in 4 out of every 10 cases thoracotomy was not done because intrathoracic or extrathoracic spread was already evident In 11% bronchoscopy showed that the tumour was in such a position that it could not be removed It is difficult to record in categories the other reasons for not operating Frequently there was a combination of factors none of which by itself might have precluded attempting resection In 7% although there was no local evidence of metastases gross wasting indicated that the disease was far advanced. The respiratory function was judged too poor to justify resection in another 6% 5 patients refused investigation or surgical treatment and 3 were incorrectly diagnosed until metastases appeared 1 was not diagnosed until after death

81 (25%) were explored, but the tumour could not be removed in 24 Resection of whole or part of the lung was therefore, carried out in only 57 (18%) of the 317 patients 52 resections were done at the Brompton and 5 elsewhere 12 had radiotherapy in addition—1 before resection 3 shortly afterwards and 8 to metastases that appeared later

120 (37%) were treated by radiotherapy alone (98 at the Royal Marsden Hospital and 22 elsewhere) For analysis the treatment has been called 'palliative' if less than a 4000r tumour dose was given and 'radical'

PHÆOCHROMOCYTOMA AND NEUROFIBROMATOSIS

ADRENOLYTIC EFFECT OF PHENTOLAMINE AND CHLORPROMAZINE

Several tests have been developed by which a phæochrome tumour can be diagnosed with certainty before operation. The main problem lies in knowing when to apply these tests, for the clinical manifestations vary considerably. Green (1946) has shown that only 30% of cases have the classic picture of intermittent paroxysms of hypertension first reported by Labbé et al (1922), sustained hypertension is the more common finding.

Smithwick et al (1950) made a notable contribution by drawing attention to certain features commonly associated with hypertension due to phæochromocytoma but uncommon in essential hypertension generalised sweating, vasomotor disturbances in the extremities, unexplained mild fever, increased basal metabolic rate, glycosuria, normal cold pressor test, and postural hypotension and tachycardia.

A further clinical contribution towards suspecting phæochrome tumours was made by Glushien et al (1953), who emphasised the not uncommon association of these tumours with the neurocutaneous syndromes, especially neurofibromatosis. In the following case a phæochromocytoma was suspected because of "dizzy attacks" and mild hypertension in a patient with generalised neurofibromatosis and was found to be present.

Case-report

A kitchen porter, aged 40, was seen in December, 1953, with eight years history of attacks of dizziness and headache. He had been discharged from the Army in 1945 with a medical category A1. Four months later, at a medical examination for re enlistment, he was found to have hypertension. From about that time he began to have sudden attacks of headache lasting a few minutes and preceded by "spots before his eyes". No other symptoms accompanied the headaches which appeared to be spontaneous and came on at irregular intervals. On a previous admission in 1951, he had bilateral apical tuberculosis generalised classical neurofibromatosis, and mild hypertension. After treatment the pulmonary tuberculosis became quiescent, and he remained well until July, 1953, when attacks of headache previously mild and fleeting, became more severe and lasted longer. Each attack consisted in "dizziness" followed by a throbbing frontal headache. When he was seen on Dec 14, 1953, his blood-pressure was 170/120 mm Hg. The association of hypertension and neurofibromatosis suggested that a phæochrome tumour might be responsible for his attacks of headache, and he was admitted for investigation.

On examination he was thin and anxious, with classical neurofibromatosis. Finger clubbing was present. Axillary hair was completely absent but facial and pubic hair were normal. The thyroid gland was normal and the skin dry. No peripheral vasomotor phenomena were observed. pulse was regular, rate 68. No apex impulse was dem strable, sounds of good quality and pure. Blood pressu 160/100 mm Hg. The optic fundi showed early hypertens retinopathy. There were signs of fibrosis at the apex of the lung. No mass was palpable in the abdomen. Nervous system urine, and blood count were normal. Fasting eosinoph 381, 520, and 312 per c mm. Blood urea, plasma-electroly and plasma protein levels, normal. Blood sugar curve insulin sensitivity normal. No paroxysm developed during the latter test. Urinary 17-ketosteroids 15 1 and 10·4 mg 24 hours. Basal metabolic rate (B M.R) +19% and +1 Biopsy of a subcutaneous nodule revealed a neurofibrom

Radiological examination (Dr A Balfour Black and c leagues) —Straight radiography of the abdomen showed small area of calcification above and medial to the upp pole of the the left kidney. An intravenous pyelogram did n show any distortion or displacement of the kidneys. Aort graphy failed because of an electric power fault. Radiograp of the lumbodorsal spine showed kyphosis of the dorsal reg associated with some arthritic changes. No congenit abnormalities.

Special tests for diagnosis —In the *histamine test* a typ paroxysm of hypertension with associated features (fig.) was produced when 0 025 mg of histamine in 0 5 ml of saline solution was injected intravenously. No albumin or sugar appeared in the urine after the test. *Phentolamine test* (Gifford et al 1952) during a phase of mild hypertension (B P 150/100 mm Hg) 5 mg of phentolamine ('Rogitine') given intravenously caused an immediate fall in blood pressure of 30/35 mm Hg. *Combined cold pressor and postural test* (Smithwick et al 1950) change in posture had no effect on the blood pressure or pulse, but immersion of a hand in ice cold water produced a typical paroxysm. *Urinary catechols* (Engel and von Euler 1950) assay of urinary catechols collected on three separate occasio gave 450, 1100, and 1800 μg in 24 hours, expressed adrenaline. The percentage of noradrenaline in the secon and third specimens was 89% and 99% respectively (Dr G West and Mr J J Lewis).

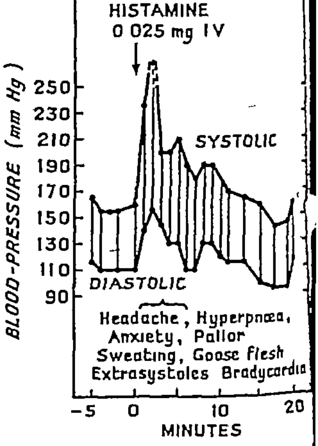

Fig 1—Paroxysm of hypertension duced by intravenous histamine.

Operation (Mr James P Galloway) —Premedication consisted of 'Omnopon' gr $^1/_3$ and hyoscine gr $^1/_{150}$ subcutan ously. In addition 20 mg of intramuscular phentolami was given to prevent the expected rise of blood pressure duri anæsthesia and operation. Anæsthesia (Dr O Watt) w induced with 0 5 g of thiopentone, and immediately thereaft 10 mg of intravenous phentolamine was given. Anæsthes was maintained with nitrous oxide and oxygen, supplemente by two doses each of pethidine (50 mg) and *d* tubocurar chloride (15 mg and 5 mg). Since a plaque of calcificati had been observed radiologically in relation to the upper po of the left kidney, exploration by the left renal approa was undertaken. Applied to the medial side of the upper p of the kidney was a hard mass as large as a walnut, wi vessels running in to the lower pole. The tumour was exc with a small portion of the suprarenal gland spread over superior aspect. Despite the administration of phentolami two hypertensive phases came on during operation (fig When the tumour was excised, the pressure was 90/60 mm. H and an intravenous drip was set up containing 4 mg noradrenaline per pint of saline solution.

Postoperatively on the patient's return to the ward t pressure had fallen to 60 mm Hg systolic owing to a block the drip, but when this was corrected the pressure promptly. The swinging blood pressure in the immedia postoperative period was caused by variation in the speed the infusion. Noradrenaline was continued for 30 hours aft operation, a total of 16 mg being given.

Convalescence was slow because of the reactivation of pulmonary tuberculosis. The attacks of headache ceased and the blood pressure remained steady at 120/80–130/90 mm Hg.

Follow-up.—During the ten months since operation the patient has had occasional attacks of dizziness unaccompanied by headache. After investigation these were attributed to Ménière's syndrome (Dr E. A. M'Connal). The blood pressure has varied between 140/100 and 165/120 mm Hg. Three histamine tests done since operation have been negative. Bio-assay of urinary catechols (Dr G. B. West) has given values of 80, 61, and 115 μg in 24 hours on three occasions. The first and third of these values are above normal, and observation is being continued to determine if another tumour is present.

The tumour measured 4·50 × 3·50 × 2·75 cm., weighed 23 g., and had a dense fibrous capsule. The cut surface revealed solid fleshy brown tissue mottled with grey and red. In the centre was a plaque of calcification. Histologically the tumour had the characteristics of a benign phæochromocytoma (Dr J. Dick and Dr H. Thomson). Bio-assay gave values of 2·644 mg. of noradrenaline and 0·661 mg. of adrenaline per gramme of fresh tissue. The tumour thus contained about 76 mg. of medullary amines, of which 80% was noradrenaline.

Discussion

ASSOCIATION WITH NEUROFIBROMATOSIS

The association of chromaffin tumours with neurofibromatosis was first noted by Eisenberg and Wallerstein (1932), emphasised by Rosenthal and Willis (1936), and reviewed by Glushien et al. (1953), who collected 17 published cases and added 1 of their own. Koonce et al. (1952) have reported 1 other case, and G. Shaw (personal communication) has investigated 1 case.

Although the over-all incidence of neurofibromatosis in published cases of phæochrome tumours is 5%, there seems to be an increasing recognition of the association between these two conditions. Since 1948 11 cases in addition to the present 1 have been reported. Either persistent or paroxysmal hypertension in a patient with neurofibromatosis thus strongly indicates the necessity to search for a phæochrome tumour.

In the present case the diagnosis was amply confirmed before operation. A spontaneous paroxysm was observed in the ward and, although minor in type from the point of view of symptoms, was accompanied by a rise in blood-pressure to 220/140 mm. Hg. Considerable variation in blood-pressure (Labbé et al. 1922, Hamilton et al. 1953) was not observed, but some lability was demonstrable when four-hourly diurnal recordings were made. The intravenous histamine test introduced by Roth and Kvale (1945) was dramatically positive (fig. 1), and more symptoms appeared during the induced paroxysm than in any spontaneous attack. The finding of an excessive amount of catechols in the urine (Engel and von Euler 1950) made the diagnosis certain. But other investigations which are often helpful (Smithwick et al. 1950) were not so in the present case. The glucose tolerance was normal; the B.M.R. was not significantly raised; the fasting eosinophil-count was not low; there was no postural hypotension; and the cold pressor test, often negative in cases of phæochrome tumour, was strongly positive. Compression of the flanks by various means did not produce a paroxysm. Thus, like the clinical picture, the results of the special investigations vary remarkably from case to case.

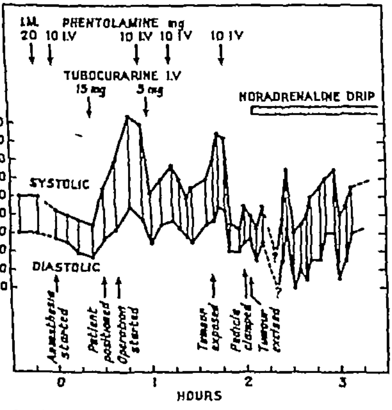

Fig. 1—Changes in blood-pressure during removal of tumour.

Localisation of the tumour, when this is small, is notoriously difficult. The walnut-sized tumour in the present case did not distort the pyelogram, but calcification in the tumour revealed its site. Since Howard and Barker (1937) reported considerable calcification in the tumour of their case, 9 others have been recorded in which flecks or plaques of calcification above one kidney have been of assistance in localisation. Cadman and Tinckler (1953) have reported 2 such cases.

The site of the tumour in the present case was the left suprarenal gland. This is in keeping with the curious observation of Glushien et al. (1953) that when a phæochromocytoma occurs in association with a neurocutaneous syndrome it is usually on the left side. Of the 21 cases reviewed by them the tumour was in the left suprarenal gland in 16 (76%), in the right in 3 (14%), and in both glands in 2 (9%). In reviewing 283 cases of phæochromocytoma without regard to their associated conditions Symington and Goodall (1953) found the left suprarenal gland involved in 33%, the right in 48%, and both glands in 9%. Analysis of these two series of figures indicates that predilection of phæochrome tumours for the left suprarenal gland in cases of neurofibromatosis is not due to chance ($p>0{\cdot}01$ $<0{\cdot}001$). The reason for this is obscure.

PHENTOLAMINE

One of the problems in the management of phæochrome tumours is the acute hypertension which may occur especially during operation. The introduction of adrenolytic agents to control such hypertension has been a major advance. The adrenolytic agent used by us was the imidazoline derivative, phentolamine (C 7337, 'Regitine'), which appears to be more reliable and much less toxic than its predecessor benzodioxane (Emlet et al. 1951, Gifford et al. 1952). The only mention of its use in this country is by Hamilton et al. (1953).

We used phentolamine in the present case for three purposes: (1) to test its adrenolytic effect during a phase of hypertension; (2) to determine if it would prevent the production of acute hypertension by histamine; and (3) to lessen the hazards of aortography and operation.

Effect on Hypertension

Several American workers (Grimson et al. 1949, Emlet et al. 1951, Iseri et al. 1951a and b, Gifford et al. 1952) have shown the hypotensive effect of phentolamine in cases of phæochrome tumour. Emlet et al. (1951) and Gifford et al. (1952) have investigated its value as a diagnostic agent for phæochromocytoma in hypertensive patients, and their results indicate that it is safe and useful. In our patient a phase of spontaneous hypertension was rarely observed; and, when we applied the test by Gifford's technique of 5 mg. intravenously, the blood-pressure fell from 150/100 to 120/65 mm. Hg. This fall of 30/35 mm. Hg is not pathognomonic, for in the series of Gifford et al. (1952) falls of this order were often observed in patients with hypertension due to causes other than phæochromocytoma. Furthermore, these workers emphasise the increased likelihood of false positive results in patients (1) with mild essential hypertension, (2) after sedation or during anæsthesia, and (3) with renal insufficiency

In the preoperative management of patients with adrenaline secreting tumours phentolamine has proved useful in controlling hypertension whether sustained or paroxysmal

Iseri et al (1951a and b) have reported successful use of oral phentolamine in 2 patients awaiting operation

Cahill (1953) and Gifford et al (1952) report the abrupt termination of histamine induced acute hypertension by giving intravenous phentolamine

But in the *prevention* of acute paroxysms of hypertension induced intentionally phentolamine has sometimes failed

In the case reported by Iseri et al (1951b) a paroxysm which would otherwise have been induced by massage of the tumour was prevented by a dose of 25 mg given orally 15 minutes beforehand, whereas on another occasion 2 5 mg given intramuscularly to the patient (a child) was ineffective Bixby and Troncelliti (1952) also record a failure of phentolamine to prevent acute hypertension induced by exercise and by histamine

Effect on Histamine Test

In our patient histamine consistently produced a paroxysm of constant pattern The effect of premedication with phentolamine on the histamine test was to reduce the symptoms substantially while diminishing only slightly the height and duration of the hypertension (compare figs 1 and 3) It is obvious that the doses given (20 mg intramuscularly 20 minutes and 10 mg intramuscularly 4 minutes before histamine) were too small to block completely the large and unknown amount of medullary amines discharged from the tumour The reduction of symptoms is noteworthy Although symptomless hypertension produced by histamine has been reported (Pantridge and Burrows 1951), in our patient all attacks not covered by an adrenolytic agent were characterised by distressing symptoms From the work of Goldenberg et al (1948) and others the symptom-producing amine is adrenaline, noradrenaline causing few symptoms or none It thus seems that phentolamine to a large extent blocks the action of adrenaline and has much less effect on the strongly pressor amine noradrenaline This is in keeping with the findings of Freis et al (1951), who showed that, in a healthy man, phentolamine, though effective in reducing adrenaline induced hypertension, only partially inhibited the pressor action of noradrenaline

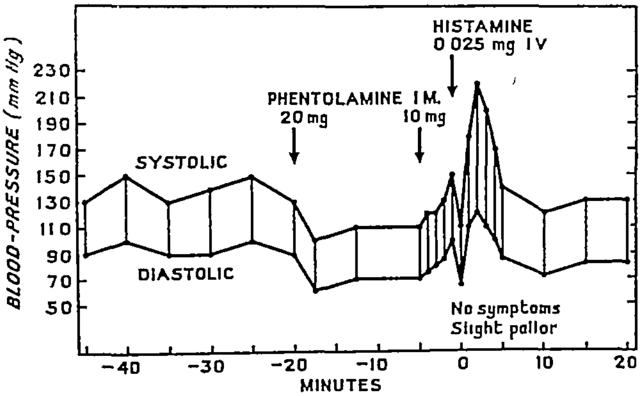

Fig 3—Effect of intramuscular phentolamine on histamine-induced paroxysm of hypertension

Effect on Blood-pressure during Aortography and Operation

st to the partial blocking action of phentolamine [illegible] histamine paroxysm, the blood-pressure [illegible] tely controlled with phentolamine during aortography, which may be fraught with considerab danger in a patient with a phæochrome tumour (Koon et al 1952) This was achieved by giving 20 mg intr muscularly 20 minutes before anæsthesia and 10 m intravenously immediately after induction with 0 5 of thiopentone Anæsthesia was maintained wi nitrous oxide and oxygen During the positioning of t patient and the manipulation of the needle the bloo pressure did not rise above 150/100 mm Hg (fig That he had had a considerable release of sympathe amines during aortography can be inferred from t hypotensive phase which followed the aortography a required noradrenaline for its correction

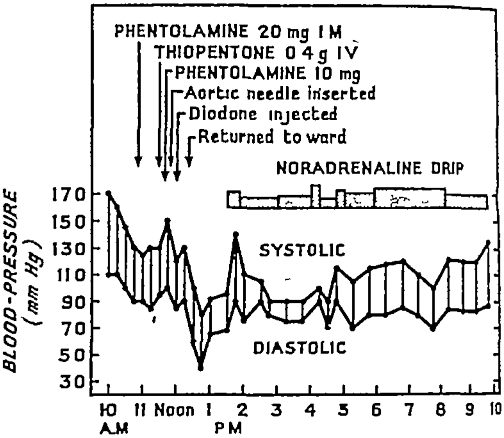

Fig 4—Control of blood pressure during and after aortography

During the operation phentolamine was very effecti in promptly abolishing hypertension when this came (fig 2) It was our object, however, to prevent hyp tension, and in this we were only partly successf Phentolamine 20 mg given intramuscularly 20 minu before anæsthesia, and 10 mg given intravenou immediately after induction, maintained normal blo pressure levels for the first 30 minutes but could prevent a major rise, which began with the injection tubocurarine and continued during the positioning the patient and the early stages of the operation hypertensive phase which appeared imminent after second dose of tubocurarine was aborted by giv intravenous phentolamine 10 mg But this was effective in preventing, 15 minutes later, the rise pressure which followed exposure and handling of tumour

In retrospect it seems that the doses we gave our pati to prevent hypertension were not large enough and not given sufficiently near an expected phase of hyp tension to be effective Yet Cahill (1953) reports that single intravenous dose of 5 mg given early in t operation successfully controlled the blood pressure un the tumour was removed 50 minutes later Emlet et (1951) maintained normal blood pressure for 2 hou after doses of 0 08–0 16 mg per kg (6–12 mg for a m weighing 70 kg), and in the patient of Iseri et al (1951 25 mg orally and 3 mg intramuscularly before operati kept the blood-pressure normal for $2^1/_2$ hours On t other hand, Bixby and Troncelliti (1952) could n prevent a serious rise in blood-pressure during eth anæsthesia by previous injection of phentolamine (do not stated) and by continuous intravenous infusion piperoxane

It is apparent that there is no standard dose phentolamine Although 5–10 mg intravenously w immediately cut short a phase of hypertension, the do required to *prevent* hypertension during operation va from case to case This is not surprising, for the am of sympathetic amine liberated by a tumour will according to the ease with which it can be stimulate by the anæsthetic agents used and by the technical operative difficulties which may arise We had the idea that useful information might be obtained on dosage of phentolamine from our attempts to block the histamine induced paroxysm; but the results though interesting were not helpful Though histamine given intravenously is a potent stimulus of tumour secretion its action is fleeting and poorly reflects the repeated and perhaps prolonged stimulation which can occur during surgical removal.

The special dangers during operation are excessive hypertension acute myocardial failure and postoperative collapse These are due to the large quantities of sympathetic amines released from the tumour especially (1) early in anæsthesia (2) during the positioning of the patient and (3) during the exposure and handling of the tumour To prevent the effects of these amines sufficient adrenolytic agent must already be occupying the receptor sites when they are liberated Since phentolamine seems to be rapidly cleared frequent doses may be necessary

For the prevention of hypertension during operation we suggest (1) administration of 20–30 mg orally or intramuscularly 20 minutes before induction of anæsthesia—Grimson et al (1951) recommend several doses to stabilise the blood pressure before anæsthesia—and (2) 10–20 mg intravenously (*a*) immediately before each of the above mentioned stages of operation when excessive secretion of the medullary amines is expected and (*b*) early on the rising slope of any threatened hypertensive phase Since the amount of amine to be blocked at any time during operation is unknown these doses may have to be modified for the individual case Doses of phentolamine in excess of requirements seem to be harmless because rapid clearance of the drug soon allows normotensive levels to be reached

As regards anæsthetic agents used in operations for removal of secreting medullary tumours certain are contra indicated—e.g cyclopropane chloroform and ethyl chloride (Papper and Cahill 1952) These tend to produce ventricular arrhythmias in the presence of excess circulating adrenaline Ether which is a known stimulant of sympathetic function has been used successfully by Papper but Bixby and Troncelliti (1952) consider it dangerous Thiopentone with nitrous oxide and oxygen were used in the two anæsthesias undergone by our patient For removal of the tumour tubocurarine was also used, and we have the impression that both intravenous doses raised the blood pressure This muscle relaxant is known to liberate histamine (Alam et al 1939) Although in patients without phæochromocytomas the small amount released by rapidly administered intravenous tubocurarine would produce few demonstrable effects, in those having such tumours it might readily release medullary hormones Such patients respond to very small quantities of histamine, in our patient 25 µg consistently provoked a severe paroxysm

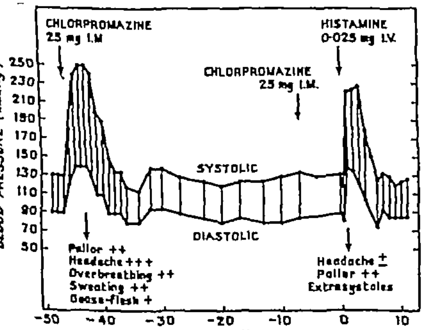

Fig 5—Effect of chlorpromazine on histamine-induced paroxysm of hypertension. The pain of the first injection of chlorpromazine induced a paroxysm (see text).

CHLORPROMAZINE

Courvoisier et al (1953) reported that chlorpromazine possessed adrenolytic properties in the dog the pressor effect of noradrenaline being reduced and the hypertensive effect of adrenaline, given in the same dose as the noradrenaline being abolished In our patient we attempted to find out how effective chlorpromazine would be in abolishing the effects of a mixture of the sympathetic amines liberated from the tumour by histamine Two doses of 25 mg were given 45 minutes and 7 minutes before 0·025 mg of histamine intravenously The first injection of chlorpromazine however, caused the patient some discomfort, and within 30 seconds he developed a typical distressing paroxysm of hypertension (fig 5) The second dose, given with some trepidation gave rise to no untoward symptoms The height and duration of the blood pressure rise provoked by histamine were almost as great as those found in previous tests without blocking agents The symptoms, however were almost abolished (fig 5) Thus like phentolamine chlorpromazine possesses a greater blocking action against adrenaline compared with noradrenaline confirming for man Courvoisier's results in the dog

Summary

A further case of phæochromocytoma associated with neurofibromatosis is reported The provocative histamine test was positive and the diagnosis was confirmed by assay of urinary catechols A plaque of calcification in the tumour localised its site in the left suprarenal gland on radiography

Pre treatment with phentolamine or with chlorpromazine strikingly reduced the symptoms of a histamine-induced paroxysm but influenced the acute-hypertension only slightly

Phentolamine prevented hypertension during aortography but did not prevent two sharp rises of blood-pressure during operation These responded promptly to intravenous phentolamine

The principles governing the use of phentolamine during resection of the tumour are discussed

Tubocurarine given during operation [illegible] phases of hypertension

ISONIAZID IN THE TREATMENT OF PRIMARY PULMONARY TUBERCULOSIS

R McLaren Todd
M A, M.D Camb, M R C P, D C H
SENIOR LECTURER IN CHILD HEALTH, UNIVERSITY OF LIVERPOOL, CONSULTANT PÆDIATRICIAN, ALDER HEY CHILDREN'S HOSPITAL, LIVERPOOL

Isoniazid was first used for treating pulmonary tuberculosis in adults in October, 1951, at the Sea View Hospital, New York (Robitzek et al 1952), and subsequently it has been used for various tuberculous conditions both in adults and in children It has usually been given with streptomycin, but it has sometimes been used alone—e g by Kendig et al (1954), who gave it to patients between 6 months and 5 years old with primary pulmonary tuberculosis They thought that it favourably influenced the course of the disease, but their conclusions were reached after treating only 8 patients and without studying a concurrent series of cases not receiving specific chemotherapy

The present investigation was undertaken to assess more critically the value of isoniazid in primary tuberculosis in children

Plan of Investigation

The children were first seen in the eighteen months between January, 1952, and June, 1953, in the outpatient department of Alder Hey Children's Hospital Many of them had been referred by the chest physicians and tuberculosis officers of the area

50 children were studied, and alternate patients in each of three age groups were given isoniazid, the remainder receiving no specific chemotherapy (table I) The results of tuberculin tests and chest radiography on admission to the investigation, and the history of contacts, are recorded in table II From the history of contact and of such clinical features as erythema nodosum it was possible in most cases to assess the approximate duration of the tuberculosis Table III shows that 43 of the 50 children had had tuberculosis for three months or less on admission to the investigation 4 children were admitted to hospital as inpatients because the adult who was the source of infection had not been removed to sanatorium, but the other children were treated as outpatients

TABLE I—AGE INCIDENCE OF 50 PATIENTS WITH PRIMARY TUBERCULOSIS

Age (yr)	Treated	Controls
Less than 3	8	9
3–6	8	9
7–13	8	8
Total	24	26

The routine therapy for all patients consisted in rest in bed for four to eight weeks, followed by a gradual return to full activity, they also received a diet ade in calories, proteins, and vitamins The treated chil received isoniazid 3 mg per lb body-weight per d divided into three doses a day, for three months. outpatients were seen monthly during the first th months and every three months subsequently At ea attendance they were examined clinically, their and height were recorded, and their chests were rad graphed In view of previous experience of a sim trial with *p* aminosalicylic acid (Todd 1953) white counts and erythrocyte sedimentation rates were estimated.

Results

The patients' progress was assessed in three ways (1) by their vitality and appetite and the re of clinical examination, (2) by records of change body-weight, and (3) by radiological evidence Of 50 children 46 were observed for twelve months, and for nearly three years

TABLE II—DIAGNOSTIC FEATURES IN 50 PATIENTS PRIMARY TUBERCULOSIS

—	Treated		C
Tuberculin test			
Mantoux 1 in 10,000	1		2
" 1 in 1 000	22		15
Jelly	1		9
Radiography			
Focus in right upper lobe	4	15	5

4	2		0	
5	1		1	
Uncertain	1		2	

infants under 3 years of age, but in the two other groups the increase in weight was greater in the tre than in the controls The rate of weight gain in the groups was compared statistically by the t test. In children under 3 years of age and in those over 6 of age there was no significant difference, but in children aged 3–6 years there was a significant differen those receiving isoniazid gained weight more rapidly th the controls

Radiographs taken after three, six, and twelve mo were compared with those taken at the first visit and results recorded in table VI Increase in the X ray sha is indicated by +1, +2, or +3, an unchanged sh by 0, and decrease in the shadow by −1, −2, or −3 (c plete resolution) There may be difficulty in interpr the significance of the radiological shadows seen

primary tuberculosis. In some cases a definite diagnosis of segmental collapse can be made, and confirmed by bronchoscopy, as in 2 of our patients, but in other cases it is impossible to distinguish consolidation from collapse. In most of our cases we took the view that the radiological shadow was due to enlarged mediastinal glands with an adjacent primary focus. After three months the shadow tended to clear earlier in the treated patients. 14 of the 24 patients showed radiological improvement compared with only 8 of the 26 controls. Statistical analysis however does not show that this difference is significant. After six months and after twelve months there were no differences between the treated and the controls.

The period which elapsed between the onset of the primary complex and the radiographic appearance of calcification in the hilar glands or at the site of the primary focus was also compared in the treated and the controls. This assessment was made after the patients had been observed for at least seventeen months, and some for thirty months, and it was found that calcification was present in 14 of 20 treated patients and in 17 of 20 controls. The average interval between primary complex and calcification in both groups was seventeen months (maximum twenty-eight, minimum ten months).

TABLE V—PERCENTAGE WEIGHT GAIN ABOVE INITIAL WEIGHT

–13						
Treated	3·1	4·7	7·1	10·5	12·5	16·1
Controls	1·0	5·0	4·4	7·2	10·1	12·2

Complications encountered were few. 2 treated patients aged 6 years and 7 years showed radiological evidence of rupture of a caseous gland into a bronchus about six months after their first visit as outpatients. The diagnosis was confirmed by bronchoscopy, the caseous material was removed, and both patients made an uninterrupted recovery.

One of the controls, aged 10 weeks when first seen, the youngest patient observed in this investigation, developed tuberculosis of the left hip eighteen months after his first visit, although the primary pulmonary lesion had healed by calcification.

There were no deaths.

Discussion

The beneficial results of chemotherapy with streptomycin, *p*-aminosalicylic acid, and isoniazid and the introduction of other measures are reflected in the decrease of the crude death rates from all forms of tuberculosis from 552 per million people in 1947 to 202 per million in 1953. Many of the patients who have survived did so in spite of the fact that they had the more serious tuberculous conditions, such as miliary tuberculosis, tuberculous meningitis, and advanced pulmonary tuberculosis.

It might be thought that specific treatment at the earliest stage of tuberculosis (primary complex) would be more effective than after the development of complications, but this has not been the general experience of pædiatricians and others who have given either streptomycin or *p*-aminosalicylic acid to children with primary tuberculosis.

Lorber (1950) found no beneficial effect of streptomycin in children with a primary tuberculous complex.

Todd (1953) found no benefit from *p*-aminosalicylic acid in 35 children with primary pulmonary tuberculosis compared with 34 controls. In a further small controlled series of 12 children under the age of 3 years, with uncomplicated primary pulmonary tuberculosis, combined therapy with streptomycin and *p*-aminosalicylic acid did not have any demonstrable effect (Todd, unpublished).

TABLE VI—RADIOLOGICAL CHANGES

Degree of change	After 3 mos		After 6 mos.		After 12 mos	
	Treated	Controls	Treated	Controls	Treated	Controls

–3	0	0	0	0	3	2
Total	24	26	21	26	20	26

The prognosis of primary tuberculosis in children varies with their age and with the age of the primary complex (Wallgren 1946). In children over the age of 3 years serious complications are uncommon, but if they do arise this usually happens within three months of the development of the primary tuberculous complex. These facts should be taken into account in any assessment of the possible beneficial effects of specific drug therapy. In the present series 43 of the 50 children were first seen within three months of the development of the primary lesion. Isoniazid seemed to have a beneficial effect on the patients' general health, judged by improved appetite and by the gain in weight observed in the children aged 3–6 years and those aged more than 6 years, although in the latter the gain in weight was not statistically significant. There also appeared to be improvement in the radiographic appearances of the treated patients when compared with the controls three months after the start of treatment, but this difference also was not statistically significant. Although the ultimate prognosis, judged on clinical grounds and on the appearance of calcification, was similar in the two groups, we formed the impression that isoniazid therapy was more often associated with decrease in size of the primary lesion during the first three months of the illness, and this is at a time when the danger of developing serious complications is greatest. A larger series of patients will have to be studied to find out if this impression is correct.

The possible harmful effects of isoniazid should also be considered. Side-effects such as vertigo, headache, drowsiness, twitching of the lower limbs, hyperreflexia, dryness of the mouth, agranulocytosis, and sulphæmoglobinæmia have been reported, but they were not observed in this series. Bacterial resistance to isoniazid is a serious complication that develops during treatment of adults with phthisis. The Medical Research Council (1953) found resistance in 9% of 181 positive cultures after a month's treatment, in 40% of 147 positive cultures after two months' treatment, and in 81% of 132 positive cultures after three months' treatment with isoniazid. Similar results have been obtained in other investigations, in which either streptomycin alone or *p*-aminosalicylic acid alone was given to adults with phthisis.

This has not been our general experience with chemotherapy of tuberculous children, but we have observed streptomycin resistance in 3 of 55 patients with tuberculous meningitis (Capon and Todd 1949) and in 1 of 8 patients with tuberculous bronchopneumonia (Todd 1949) Sweetnam and Murphy (1954) discussed the possible emergence of resistant strains of tubercle bacilli in children with miliary tuberculosis treated with isoniazid alone They considered that, because of the relatively small amount of fibrous tissue reaction, there was no barrier to the action of isoniazid, and that the development of drug resistance was therefore only a very remote possibility In the present investigation no attempt was made to isolate tubercle bacilli from gastric washings and to estimate the sensitivity to isoniazid, because the patients were living at home, but, from the satisfactory progress they made, it is unlikely that they suffered harmful effects from this form of chemotherapy

Summary

Isoniazid, 3 mg per lb body weight per day, was given to alternate patients, in a series of 50 children with primary pulmonary tuberculosis, for three months

The children receiving isoniazid gave a better clinical response than did the controls, particularly as regards appetite The gain in body-weight of children aged 3–6 years was significantly greater in the treated than in the controls X-ray shadows also tended to clear earlier in the treated than in the controls The clinical and radiological condition after from one to three years did not differ in the treated and the controls

The risk of the development of drug resistance is discussed

A larger series of patients will have to be studied to find out whether isoniazid is of value in the treatment of primary pulmonary tuberculosis

I wish to thank Prof Norman B Capon for his help and advice, and Mr R L Plackett, M.A, of the department of applied mathematics in the University of Liverpool, for help with the statistics

COMBINED LEFT PNEUMONECTOMY, THORACOPLASTY, AND LIGATION OF PATENT DUCTUS ARTERIOSUS

J R Edge
M D Leeds, M R C P
CONSULTANT CHEST PHYSICIAN

J S Glennie
M D Aberd, F R C S E
CONSULTANT THORACIC SURGEON

HIGH CARLEY HOSPITAL, ULVERSTON, LANCASHIRE

Successful ligation of a patent ductus arteriosus was first described by Gross and Hubbard in 1939, and since then this operation has become a commonplace of cardiac surgical practice If the condition is left untreated the ex[illegible]n of life is much reduced, owing to the risk of [illegible]larteritis and of endocarditis, and of cardiac [illegible] the increased work done by the heart as a

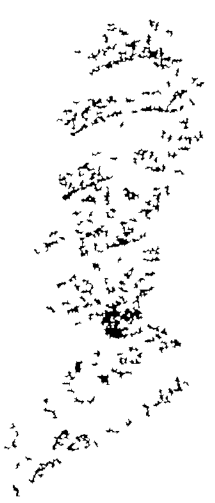

Fig 1—Radiograph of chest, Aug 3, 1954

result of the shunt The operative mortality is as as 2–3% (Gross 1947, Crafoord 1948), but Wood (19 advises against operating routinely on mild symp free cases

Surgical resection of lung tissue for tuberculosis been practised from time to time since the first report Tuffier in 1891, but both the immediate mortality and the subsequent morbidity from bronch pleural fistula remained extremely high until the adv of chemotherapy

Conklin et al (1951) reported favourably on practice of combining thoracoplasty and resection in single operation, they used this technique when presence of disease in the opposite lung, or in any ing lung on the operated side, made it advisable to over expansion of the residual lung tissue, with attendant risk of reactivation In this hospital combination of resection and thoracoplasty in operation has been standard practice in suitable cases the past year

We have been unable to find any reported instance of patient undergoing pneumonectomy, thoracoplasty, ligation of a patent ductus arteriosus at a single opera as in the case described here

Case-report

A housewife, aged 35, with four children was found to be early pulmonary tuberculosis in 1943, when radiography her chest showed limited infiltration in both upper zones. this time she was told that there was "a murmur in heart" After a short period of general treatment in sanatorium she was kept under observation as an o and she remained quite well until 1952, when she became with severe anæmia and persistent slight pyrexia admission to hospital at that time she had typical signs patent ductus arteriosus, and the spleen was palpable, cultures on three occasions showed a heavy growth of α hæmolytic streptococci The infective endarteritis was treated penicillin 250,000 units three hourly and streptomycin 0·5 twice daily, for six weeks, her symptoms were comple relieved, the fever settled, and subsequent blood cultures negative She was then referred to another hospital, ligation of the ductus was considered but not proceeded wi Radiography of her chest at this time showed no evidence reactivation of tuberculous disease, and she returned to household duties She remained well until early 1954,

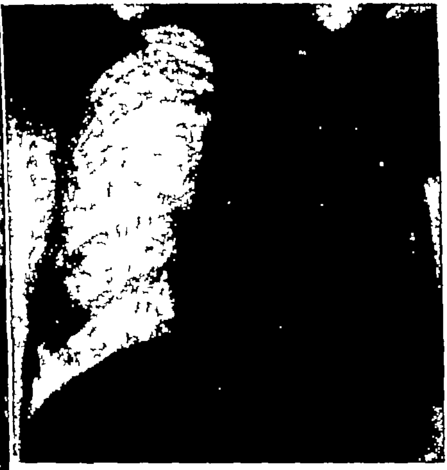

Fig 2—Radiograph of chest fifteen days after operation.

she developed a productive cough felt very unwell and lost weight She was first seen by one of us in May 1954

On examination her general condition was poor There was a continuous murmur together with a systolic thrill, in the second left intercostal space the blood pressure was 100/30 mm. Hg There was no finger-clubbing Radiography showed considerable spread of the tuberculous disease in the left upper lobe where there was a large homogeneous oval opacity—evidently a blocked cavity—and there were scattered though limited fresh opacities in the right upper zone The heart was not greatly enlarged, but screening in the left anterior oblique position revealed some prominence of the left ventricle The sputum was positive for tubercle bacilli for the first time

On admission to High Carley Hospital on Aug 2 her general condition had greatly deteriorated she was feverish and extremely ill, and radiographic examination (fig 1) showed that the contents of the lesion in the left upper zone had been evacuated leaving a large thick walled cavity; there was extensive bronchogenic spread of disease to the left lower zone mainly to the lingula

Treatment with postural rest and chemotherapy (streptomycin 1 g. daily and isoniazid 250 mg daily) was begun and after two months there was very striking improvement in her general condition. Radiography showed blocking of the large cavity in the left upper lobe some slight contraction of the massive spread in the left lower zone and almost complete disappearance of the small lesions in the right lung Bronchoscopy revealed no sign of significant endobronchitis; blood cultures were repeatedly negative

At this stage—no doubt because of her considerable symptomatic improvement and numerous domestic anxieties—the patient became very restless and it seemed unlikely that she would accept long-continued hospital treatment We had therefore to consider immediate definitive treatment for her condition was clearly still precarious The risk of circulatory failure following pneumonectomy in the presence of a patent ductus with increased pulse pressure was unquestionably grave We therefore decided to do a thoracotomy to ligate the ductus, and (if the patient's condition was still satisfactory) to proceed there and then to resect the diseased lung tissue We calculated that the risk of bronchogenic dissemination of disease following thoracotomy would be considerable unless the tuberculous lesions could be dealt with at the same time

Operation (Nov 1)—The dissection of the ductus was complicated by the presence of many adherent glands the vessel the wall of which was not unduly thickened was ligated with two floss silk ligatures The radiographic finding of disease limited largely to the upper lobe was confirmed by palpation; dissection of the hilum was extremely difficult owing to the presence of many glands adhering to the pulmonary artery and its main branches and in freeing one of these glands the main pulmonary artery was damaged and could not be repaired It was consequently necessary to proceed to pneumonectomy instead of to lobectomy as intended On completion of the pneumonectomy the patient's general condition remained satisfactory and so the upper four ribs were removed to minimise the likelihood of subsequent mediastinal displacement

Progress—The postoperative course was singularly uneventful; within a few days the patient's general condition had greatly improved and all signs of toxæmia had disappeared the blood pressure became established at 120/60 mm Hg and the continuous murmur was replaced by a short low pitched mid systolic pulmonary bruit The radiographic appearance fifteen days after operation is shown in fig 2

At the time of publication the patient remains in excellent health, has no cough or sputum, and does not complain of dyspnœa on ordinary exertion She is up all day and will be discharged home in the next few weeks.

Summary

A woman aged 35 with extensive pulmonary tuberculosis and patent ductus arteriosus previously complicated by infective endarteritis was successfully treated by combined ligation of the ductus, pneumonectomy and thoracoplasty at a single operation

Our thanks are due to Dr C P Brown, whose skill in anæsthesia made this operation possible and to Dr A. P B Waind for information about the patient when she was under his care in 1952 for the treatment of infective endarteritis.

NEW SHORT-ACTING THIOBARBITURATE

PETER NOBES
M.B Lond. F.F.A. R.C.S D.A
ANÆSTHETIC REGISTRAR, CHASE FARM HOSPITAL AND THE ENFIELD GROUP OF HOSPITALS MIDDLESEX

IN anæsthesia for outpatients both hexobarbitone and sodium thiopentone have the great disadvantage that somnolence may persist after the operation

Weese and Koss (1954) and Dietman (1954) have described experimental and clinical experience with 'Baytenal' a new very short acting anæsthetic which is apparently eliminated from the body so rapidly that its administration is followed by little, if any postoperative somnolence

This drug is sodium 5 5 allyl (2 methyl propyl) thiobarbiturate. It is issued as a powder, which is readily soluble in water and is administered as a 10% solution which according to the manufacturers is stable for thirty six hours It is not at present on sale in this country

Weese and Koss (1954) based their observations on 350 cases

Their series included inpatients many of whom were ill and debilitated these were given premedication but morphine and its derivatives were avoided Outpatients were given no premedication and all types of surgical oper[illegible] lasting up to 10 minutes were undertaken. [illegible] the av[illegible] adult they injected 2–3 ml. of the 10% s[illegible] rapi[illegible] and after about 1½ minutes a further

TABLE I—FINDINGS WITH BAYTENAL IN FIVE INPATIENTS

Case no	Age (yr.)	Sex	Operation	Premedication	Dose of baytenal (g.)	Duration of unconsciousness (min.)	Time after initial injection until patient sat unaided (min.)	Nausea or vomit
1	28	F	Removal products of incomplete abortion	Omnopon gr. $^1/_3$, scopolamine gr. $^1/_{150}$	0·5	$16^1/_2$	30	Momentary retch on recovery
2	54	F	Sigmoidoscopy and biopsy rectal neoplasm	Omnopon gr. $^1/_3$, scopolamine gr. $^1/_{150}$	0·5	14	40	Slight retching awakening
3	36	M	Perianal injection 'Proctocaine'	Omnopon gr. $^1/_3$, scopolamine gr. $^1/_{150}$	0·45	6	16	Nil
4	25	M	Incision ischiorectal abscess	Nil	1·0	7	11	Nil
5	[illegible]	M	Manipulation of left knee	Omnopon gr. $^1/_3$, scopolamine gr. $^1/_{150}$	0·6	4	27	Nil

on the depth of narcosis or duration of operation. In no case did the total dose exceed 1 g. Where muscular relaxation was needed succinylcholine was administered.

Weise and Koss emphasise that, because of the freedom from subsequent excitement, the slight respiratory depression, and, above all, the very rapid elimination of this drug, the patients needed no supervision after *operation: there was no vomiting or other complication. Outpatients were able to leave the operating-theatre within a few minutes of the end of the operation, and to go home in 20–30 minutes.*

Clinical Trial

A clinical trial of baytenal has been undertaken at Chase Farm Hospital. Because little of the drug was available the series included only eleven patients. Their ages ranged from 17 to 62, and, in order to obtain an unobscured picture of the effects of the baytenal, cases were selected to exclude so far as possible those where the addition of long acting relaxants, inhalational agents, or other intravenous drugs would be necessary.

The inpatients, with one exception, received premedication with 'Omnopon' gr. $^1/_3$ and scopolamine gr. $^1/_{150}$. The outpatients received no premedication, with the exception of one who was given atropine gr. $^1/_{100}$. Baytenal was given mostly in a single dose, injected as rapidly as possible. The dose was estimated on the basis of the patient's age, weight, and general condition and the probable duration of the operation. During anæsthesia some patients breathed air, while others received a nitrous oxide/oxygen mixture at the rate of 5 and 2 litres per minute respectively either immediately following the injection or after several minutes where return of consciousness seemed likely before the end of the operation. Particular attention was directed to the duration of unconsciousness, judged by the time taken by the patients to register complete awareness of surroundings in response to questioning. The degree of respiratory depression, the time which elapsed before the patients were able to sit or walk unaided, and the presence or absence of excitement, amnesia, and nausea or vomiting were noted.

The results are summarised in tables I and II.

Experimental Observation

The drug was administered experimentally to a volunteer (P. N.).

The blood pressure was recorded and spirometry trac were taken by two observers. No premedication was gi the spirometer facepiece was applied, and time given become accustomed to the apparatus.

Baytenal 0·6 g. was given slowly over a period of minutes. Rapid loss of consciousness occurred, preceded b brief sensation of drowsiness; no taste was experienced blood pressure fell from 138/90 to 120/80 mm. Hg and pulse rate rose from 72 per minute to 120 per minute. slight depression of respiratory amplitude was registered on spirometer, but respiratory rate was unchanged. Afte further $1^1/_2$ minutes baytenal 0·4 g. was injected as qui as possible. This injection was followed by a slight fall in rate and volume of respiration, which returned to nor within 2 minutes. 2 minutes after this second injectio painful stimulus (digital pressure over the brachial ple caused increased depth and rate of respiration.

6 minutes after the initial injection the subject rega consciousness. He had no mental confusion whatever was able to answer questions regarding time and pl there was no retrograde amnesia. After a further 6 min he was able to walk in a straight line, and within 22 min from the first injection was able to write an account of jective sensations. The return to full consciousness was re Slight euphoria persisted for about 2 hours, but this n way impaired the sense of wakefulness, nor the ability drive a car and carry on with normal work within that per This contrasted strongly with the 3–4 hours of pronoun somnolence experienced by the subject after 0·2 g. of sod thiopentone a week previously.

Discussion

The most striking feature in this series was the short time in which patients regained normal consci ness with freedom from postanæsthetic confusion drowsiness. Equally important was the very s interval between recovery of consciousness and re of ability to sit, stand, and walk unaided. Du anæsthesia respiratory depression was very slight, in no case (except where succinylcholine was used) apnœa of more than a few seconds' duration app Retching occurred in only three cases, and lasted about $^1/_2$–1 minute; two of these three patients received omnopon gr. $^1/_3$ and scopolamine gr. $^1/_{150}$ premedication. In five cases a normal meal was tal within 2 hours after the anæsthetic. It would seem th if the "single dose" technique is used, at least 0·5 should be given to an adult patient.

Baytenal may prove of special value for casualty outpatient cases where it is particularly desired to av

TABLE II—FINDINGS WITH BAYTENAL IN SIX OUTPATIENTS

Case no	Age (yr.)	Sex	Operation	Premedication	Dose of baytenal (g.)	Duration of unconsciousness (min.)	Time after initial injection until patient sat unaided (min.)	Nausea or vomiti
6	61	F	Reduction of Colles fracture	Nil	0·4	5	10	Nil
7	61	M	Incision septic thumb	Atropine gr. $^1/_{100}$	0·75	$9^1/_2$	13	Nil
8	25	F	Incision breast abscess	Nil	1·0	15	28	Sl. moment. retch
9	55	F	Manipulation of knee	Nil	0·25	1	Immediate	Nil
10	[illegible]	F	Manipulation of ankle	Nil	0·5	$2^1/_2$	$3^1/_2$	Nil
11		M	Manipulation of knee	Nil	0·45	4	7	Nil

the unpleasantness of induction with an inhalation anæsthetic but where it is also important that the patient is ambulant within a very short time Because of its rapid elimination it may be worth trying its administration by continuous drip infusion for longer operations. The contra indications to sodium thiopentone should be applied equally to baytenal though this drug causes less severe respiratory depression and may thus be more suitable for " poor risk " cases.

Summary

A new short-acting thiobarbiturate ' Baytenal ' has been tested in eleven patients and in a healthy volunteer

This drug depresses respiration very slightly

It may prove particularly useful for anæsthesia in outpatients because of the rapid return of consciousness and the absence of postanæsthetic somnolence and confusion

My thanks are due to Dr P W S Gray and Dr D Zuck, consultant anæsthetists to Chase Farm Hospital, for their help and encouragement in the preparation of this paper I am also grateful to Messrs Bayer of Leverkusen Germany for a supply of Baytenal

Induced Hypothermia

THE anæsthetics section met on April 1 under the chairmanship of Dr BERNARD JOHNSON president of the section to discuss Induced Hypothermia

Dr C. F SCURR observed that tissue anoxia due to circulatory arrest unless rapidly relieved led to cellular death ; but if the body temperature was lowered cellular metabolism and oxygen demands were reduced so the cells survived the anoxia for longer periods A hypothermic technique might be valuable for intracardiac operations for transposition of the great vessels for operations for congenital cyanotic heart-disease, for certain intracranial operations, and for some abdominal and thoracic operations such as excision of an aortic aneurysm. There were five advantages to be gained First, the oxygen requirements of the tissues were reduced since if shivering was prevented oxygen consumption fell in a linear fashion with fall of body temperature Secondly cardiac work was reduced Thirdly the coagulation *time of the blood was increased which* might be beneficial in certain types of cardiovascular surgery where thrombosis was a potential danger Fourthly anæsthetic requirements were reduced Fifthly harmful bacterial and enzyme activity was suspended Dr Scurr noted several disadvantages which necessitated special care on the part of the anæsthetist such as a tendency towards carbon-dioxide retention a shift to the left in the oxyhæmoglobin dissociation curve and a retardation in the elimination of non volatile anæsthetic agents Moreover the heart rate cardiac output and blood pressure were all decreased with a tendency to cardiac irregularities at levels around 25°C Such irregularities presaged ventricular fibrillation ; and because of this continuous electrocardiographic control was in Dr Scurr's opinion essential Sinus bradycardia with normal complexes had usually been seen in his cases. During rewarming after cooling might occur owing to the opening up of the peripheral circulation with the transfer of very cold blood to the main circulation A further fall in the central temperature from this cause might lead to ventricular fibrillation and death

Dr SCURR described how he induced hypothermia in small children under light anæsthesia and oxygen perhaps with a muscle relaxant to prevent shivering He used a cooling blanket through which circulated water at 2–4°C

Dr T C GRAY (*Liverpool*) described the results of induced hypothermia in 110 patients almost all adults He advocated surface cooling and demonstrated the technique with a colour film Hypothermia was induced during light anæsthesia with a muscle relaxant, and under the vasodilator effect of chlorpromazine There was no shivering and an adequate temperature fall could be obtained in one and a half hours The tendency towards an ' after drop ' in temperature when active cooling ceased could be prevented by tilting the patient at fifteen minute intervals to prevent local accumulation of blood. Dr Gray showed that this ' after-drop " was most common in patients with a large surface area whose temperature fell slowly during cooling He thought that this technique was altogether more satisfactory than intravenous administration of a mixture of chlorpromazine, promethazine hydrochloride, and pethidine followed by surface-cooling which was slow in effect and often complicated by shivering

He and his colleagues had used induced hypothermia for intrathoracic neurosurgical, and general surgical operations Hypothermia had also been produced therapeutically, but without *conspicuous success.* In neurosurgery its particular value seemed to be the increased safety with which induced hypotension could be used for long periods with the patient in the upright position, while in general surgery a low temperature seemed to *offer some protection against the effects of surgical* trauma this was most obvious in poor risk patients. In the whole series of 110 cases there were 13 deaths These were very *poor risk patients* but 3 of the deaths among patients submitted to neurosurgical operations were *from pulmonary embolus and Dr Gray thought* there might be some significance in this

Attempts to measure the pituitary adrenal responses of patients to surgical stress with and without induced hypothermia had not yet shown much difference, but *from experimental work on dogs Dr Gray thought* there was evidence that these responses were modified to the ultimate benefit of the animal

In the discussion that followed, Dr J W DUNDEE (*Liverpool*) remarked on the particular value of induced *hypothermia for neurosurgical cases* In one case he described the surgeon had clamped the middle cerebral artery for seven and a half minutes without postoperative sequelæ.

Dr B G B LUCAS remarked on the difference between *the tolerance of the brain and of the heart for ischæmia* during induced hypothermia The heart was more susceptible under these conditions than the brain—a reversal of the order at normal temperature—which suggested that the future of very deep hypothermia might lie in methods of *reducing heart work*

Mr C E DREW suggested that hypothermia was of great value for operations on congenitally cyanotic children particularly when it was not possible to tell preoperatively what surgical procedure might be necessary The antithrombotic effect was probably of value when an anastomosis was performed

Dr G J REES (*Liverpool*) doubted whether hypothermia was ever of value for the Blalock shunt operation He remembered anæsthetising a child with congenital heart-disease and cyanotic coma—*a very severe case*—with a successful outcome He considered that if this was possible with a standard *anæsthetic technique* then it was unnecessary to submit the child to further risks

Reviews of Books

Brain Mechanisms and Consciousness

A Symposium organised by the Council for International Organisations of Medical Sciences Consulting Editors EDGAR D ADRIAN, United Kingdom, FREDERIC BREMER, Belgium, HERBERT H JASPER, Canada Editor for the Council J F DELAFRESNAYE Oxford Blackwell Scientific Publications 1954 Pp 556 42*s*

THE members of this symposium met to discuss eighteen papers which they had already circulated among themselves These papers, with condensed verbatim reports of the ensuing discussions, form the substance of this book

The matter falls into three categories First, experimentalists describe the rousing effect of thalamic stimulation on the massed electrical activity of the cerebral cortex in various animals, and trace impulse traffic in cortex and reticular formation with micro electrodes Second, clinicians show that consciousness in man is disturbed by molesting centrencephalic tissue, and investigate the psychical correlates of abnormal electro encephalograms which parallel those artificially induced in animal brains Third come some broader based psychobiological essays which come really closest to the purpose of the symposium

Nerve impulses reach the cerebral cortex from the receptors along topographically organised channels An unsolved problem, as Lord Adrian points out, is the nature and site of the blocking process that has to be invoked to explain how, of all signals thus reaching the cortex, some are attended to and some are not The main afferent pathways are distinguished, in contemporary theory, from "non-specific" reticulo-cortical projections which diffusely activate the cortex Our scientific heirs may not agree with the notion that these so-called non specific projections constitute a single system, and may smile on the mid-twentieth-century tendency to view the reticular formation as a single anatomical and functional entity

Full publication of such proceedings is necessary for the specialist, but makes for an unwieldy book The report might have been more acceptable if it had taken the form of a précis devised by a single writer, but truncation of the massively intelligent essays of Fessard, Hebb, and Láshley would be unforgivable. This account leaves a strong impression that the study of consciousness is still a proper province for psychological and philosophical investigators, and that the neural complexity already revealed by the physiologists can provide as many neural models as may be required, without enforcing the claims of any one of them

Clinical Cytology

Using the May Grünwald Giemsa Stained Smear Vols I and II P LOPES CARDOZO, M D, consulting physician and lecturer in hæmatology and cytology, Universities of Leyden and Amsterdam Leyden L Stafleu 1954 Pp 128 and 191 72 50 guilders

INTEREST in cytological methods of tumour diagnosis is spreading on the Continent Partly because Papanicolaou's work which was the first to gain wide recognition for cytological methods, was in this field, and partly perhaps because it is more susceptible to mass-production methods than any other, vaginal cytology has nearly always occupied a prominent place in studies on cytological tumour diagnosis, and the first of these two books is concerned solely with this technique The views expressed, backed by an experience of 15,000 examina- unspectacular but sound The illustrations usual lithograph-like quality which in these days of ever-glossier reproduction is grateful to the e and seems to involve no loss of detail

Dr Cardozo's book is more unusual He hold hæmatology to be the first branch of diagnostic cytolog and claims the whole subject as a legitimate exten of the methods of hæmatology His use of hæmatolog techniques in staining cells is characteristic

He deals with skeletal lesions—using especially a "preci location" puncture of localised lesions, often under th fluoroscope—cervical lymphadenopathies, thyroid tum lung tumours, both by sputum and by direct puncture c pleural and ascitic fluids A chapter on diagnosis of prost carcinoma, using cytological examination of material expres by prostatic massage, is contributed by Dr J Posthuma n claim for 96% of positive smears in prostatic cancer pr justified this may prove a most valuable new method.

Dr Cardozo is an enthusiast, and sometimes a litt less than fair to other methods of diagnosis, but he written a readable book, valuable especially for unconventional approach to a subject often treated rather narrow lines The translation is just imp enough to retain a flavour of the original language witho losing anything in sense, and the coloured phot micrographs (in a separate volume) are excell Only the price is likely to detract from a deserv popularity

Dental and Oral X-Ray Diagnosis

A. C W HUTCHINSON, D.D S, M.D S, F D S, F professor of dental surgery, University of E Edinburgh and London E & S Livingstone 19 Pp 524 75*s*

THE 29 chapters of this book range from develop and normal anatomy through dental pathology to ger diseases of bone Professor Hutchinson is not a r logist, and this has its disadvantages and perhaps advantages

The reproduction of the intra oral radiographs among many illustrations of wide range is good Unfortunately extra oral views are rarely of the same standard, for most them are too dark X ray films are notoriously difficult reproduce, as many authors sadly discover, but it is a pity the high standard of reproduction of the dental films has been maintained in those of the skull and jaw All obl lateral radiographs of the mandible and temporomandib joint have been printed as if viewed from the tube side— is, through the patient—while intra orals (quite are presented as viewed outside the mouth Thus the teeth in the two groups appear to belong to opposite and this is confusing The anatomy is well presented, pathology is extensively and, in most instances, well Description of the radiographic appearances is more me There is a full bibliography after each chapter

Apart from some minor errors this is a valuable notably for its collection of radiographs P Hutchinson offers his readers sound advice, based on experience, on the value and limitations of radiograp evidence

Nerve Blocks

A Manual of Regional Anesthesia for Practitioners Medicine JOHN ADRIANI, M.D, director, department anesthesiology, Charity Hospital of Louisiana Springf Ill Charles C Thomas Oxford Blackwell Sc Publications 1954 Pp 265 47*s* 6*d*

Dr Adriani is well known and respected as a of several lucid and factual works on anæsthetic sub and this volume on local analgesia is an admi addition to his series It is not complete, nor is it int to be, but it does give a very clear and helpful acco of the principal techniques, including those of spinal epidural analgesia Although in this country gen anæsthesia is usually preferred to any form of local, th procedures still have many valuable uses, not only surgery but in therapeutics

Scoliosis

CURVATURE of the spine may manifest itself at most any time during the period of growth, and articularly in early adolescence There are many nown causes, but the ætiology of the ordinary or "idiopathic," scoliosis is quite unknown. The ancients ave little to say on the subject, and even ANDRY who coined the word "orthopædics ") is for once at loss Later workers have tended to accept the views well expressed by ROYAL WHITMAN[1] Lateral urvature was regarded as one of the penalties of the rect posture The predisposing conditions were eneral weakness from any cause fatigue from over ork, and all factors that might enhance the difficulty f holding the trunk erect under the pressure of the uperincumbent weight Both heredity and occupa on were thought to be exciting factors , and even abitual posture—for example, slouching at a school esk of the wrong height and the posture during eep—was incriminated Later, psychological factors ere taken into account BLUNDELL BANKART used tell his students "you recognise the presence of scoliosis by looking at a child's back, but if you ant to find the cause you look at the mother's face nd the boring teacher rather than ill designed school urniture was blamed for slouching

This approach has led nowhere It is only during e past few years that serious attempts have been ade to solve the problem NACHLAS and BORDEN[2] oduced curvature in dogs by preventing growth on ne side of the vertebral bodies where the epiphyses ere bridged with staples SOMERVILLE[3] on the basis experimental evidence described a chain of events ading to scoliosis which was initiated by structural rdosis arising from failure of growth of the posterior ements of a segment of the spine (i e, all those arts of the vertebræ lying behind the bodies) ARKAS[4] after a detailed anatomical pathological nd radiographic study has advanced a somewhat ifferent view He describes different processes for e thoracic and lumbar regions Thoracic curves start o believes, in the cervicothoracic segment during e first four years of life and several years may pass efore the middle and lower thoracic regions are volved He believes that the basic pathological rocess consists in separation of the epiphyseal ring om the rest of the vertebral body and its partial splacement Moreover he thinks that this separation preceded by an infantile form of osteoporosis of e spine Lumbar scoliosis he attributes to con nital anomalies in the articular system of this region hich permit rotation of the vertebræ Perhaps the ews of both SOMERVILLE and of FARKAS will prove to be soundly based, because it is most unlikely that all "idiopathic" scolioses have a single cause, but much has yet to be learnt before either view can be accepted

The treatment of structural scoliosis is singularly difficult because the bones of the vertebræ are abnormal in shape Ideally the deformity would be prevented from occurring at all, but this is hardly feasible until more is known of the ætiology Deformity in the adult cannot be corrected, the shape of the fully grown bone can be changed only by carpentry, which so far has proved impracticable Attention has therefore been directed chiefly to preventing increase in deformity after this has been recognised, and to influencing the forces acting on the developing bones in such a way as to modify their shape during growth It can hardly be said that scoliosis was treated at all, until a generation ago when the great pioneers of orthopædic surgery attacked the disorder with corrective plaster casts spinal braces and gymnastics They succeeded, by close attention to detail by dogged perseverance, and above all by displaying such enthusiasm as secured the willing coöperation of the patient, in giving many a potential victim the semblance of an erect posture But no cure was possible no scoliotic could be made straight, and the most that could result from years of conscientious work by surgeon, physiotherapist, and patient was a balanced and reasonably supple body Today little more than this is possible, and modern methods are no more than refinements of the old The plaster cast applied during extension has been replaced by the hinged cast associated with the name of RISSER, the brace has been greatly improved, notably by BLOUNT, of Milwaukee and any correction gained can now be held by fusing long lengths of the spine. A few brave surgeons have strayed from the well trod paths The latest of these are ALLAN,[5] of Birmingham, who has inserted into the spine an apparatus with an internal turnbuckle which spans the concavity of the curve and forces the ends apart, and ROAF[6] of Liverpool, who in specially selected cases has excised a wedge from the vertebral bodies at the apex of the curve Such operations are still on trial

It is difficult to compare the results of the later methods with those of the earlier, because only in the past few years has it been possible to assess the prognosis in an individual patient In the past many underwent years of energetic treatment including spinal fusion, even though the curve was of a type unlikely to progress, and the results were correspondingly favourable Now thanks to the work of PONSETI and FRIEDMAN,[7] JAMES,[8] and several others, it is possible to foretell at an early stage and with reasonable accuracy, which curves are likely to develop to a crippling degree Modern reports of the results of treatment refer only to the curves likely to become severe—about 5% of all—for these are the only ones that are now subjected to energetic treatment whereas the older surgeons included scoliosis of every pattern and grade The best that can be achieved with a very severe curve is to reduce the angle by perhaps 50% and restore, or greatly improve, the balance of

the trunk The patient (more often a girl) thus reverts to a condition in which, when fully clothed, she is not obviously deformed and can face the world with greater equanimity The price she pays for this is a long stay in hospital, with immobilisation in a grotesque position and perhaps several major operations, and her back may still become painful later in life

What of the lesser thoracic curves that are treated only by remedial exercises designed to keep the body supple and of the lumbar curves that often pass unrecognised for many years ? These are not so unsightly as to be an embarrassment during youth, but only too often they give rise to crippling pain in later life They are very much commoner, and they present an even greater challenge to the surgeon, than the more severe deformities Here there has been no real advance in a thousand years we can neither prevent them from starting nor influence their course We are unlikely to do so until as much effort is directed to ætiology as is now devoted to the mechanics of treatment

Infection Before Birth

INTRA-UTERINE infection as a cause of perinatal mortality has not attracted the attention it deserves Forty years ago SLEMONS[1] indicated that placental bacteræmia was an important cause of fœtal death late in labour, and BROWNE[2] subsequently drew attention to the occurrence of intra-uterine pneumonia Yet relatively few detailed pathological and bacteriological studies of this condition have been described DOUGLAS and STANDER[3] showed that blood-cultures from infants stillborn after prolonged labour associated with intrapartum infection were usually positive, and in over half of this group the placenta showed histological evidence of acute infection LABATE[4] demonstrated pathological evidence of pneumonia in 8% of 868 consecutive necropsies of stillborn or neonatal infants CORNER and his associates[5] stated that asphyxia was the most important pathological finding in 79% of 53 stillbirths and neonatal deaths associated with prolonged labour Of their whole series of 1233 perinatal deaths 82 (6 6%) were found at necropsy to be due to infection, the commonest cause was pneumonia, which was often associated with prolonged labour and evidence of " chorioamniotitis " SIDDALL[6] demonstrated inflammatory changes in the placenta, amnion, chorion, and umbilical cord

It seems that many newborn who develop pneumonia in the first week of life have been infected in utero AHVENAINEN[7] found a surprisingly high incidence (63%) of pneumonia in 674 necropsies of live born infants in the Children's Clinic, University of Helsinki , in 15% pneumonia was judged to be the sole cause of death Half of these children died in the first week of life, but surprisingly there was no convincing statistical evidence that the incidence of pneumonia was higher after complicated than after uncomplicated labours , nor was there a close correlation with neonatal asphyxia BLANC[8] sised the importance of early diagnosis of infecti the newborn The time interval, anoxia, micro virulence, and prematurity may all influence relationship between maternal and fœtal infecti symptoms of maternal infection and the co of labour are not reliable guides to the of the fœtus In his opinion ascending infec never involves the fœtus in the absence amniotic inflammation He detects such inflam tion by placing on a slide a shred of am from near the large placental vessels with its plac surface downwards, and staining this as with a sm Examination of endotracheal or gastric fluid aspir from the infant gives immediate proof of contamina

Other workers, seeking to combat infection prom have made out a case for the prophylactic tration of antibiotics to the mother when labou prolonged, particularly when the membranes been ruptured for some hours CHARLES[9] has cribed interesting work on the placental transm of antibiotics WOLTZ and his associates[10 11] rep in 1945 that penicillin crossed the placental b as early as the tenth week of pregnancy , and peni given late in labour was detected in the fœtal bl concentrations of from a quarter to a half that i maternal blood[12 13] Clinical experience, notab the treatment of syphilis,[14] supported these la findings , and subsequently the passage of str mycin, chloramphenicol, and aureomycin throug placenta was reported Ross et al[15 16] point the need for maintaining a high maternal blood of antibiotic to ensure transference to the f CHARLES now concludes that penicillin, strepton chloramphenicol, aureomycin, and tetracycline a transferred from the maternal to the fœtal orga in therapeutic concentrations Of these subst all except penicillin enter the liquor amnii or negligible amounts Penicillin is retained in the amnii, where its level remains high even afte maternal serum level has greatly fallen T difficult to explain since all these substances similar molecular weight and apparently the sodium, and possibly other constituents of the am fluid are rapidly exchanged with the mat serum[17 18] CHARLES suggests that the am membrane absorbs penicillin selectively

EASTMAN[19] states that in the managemen uterine inertia " because of the threat of intrapa infection whenever the membranes rupture pr turely it is customary to administer penicillin sulphadiazine in cases in which the membranes been ruptured 12 hours or more " In this co such a practice is perhaps less usual , for the emerg resistant strains of staphylococci has tempered husiasm for large-scale prophylactic administration antibiotics Bowie[20] points to the increasing portance of staphylococci in genital tract infections is highly desirable that we should know what tential pathogens exist in the genital tract fore embarking on the administration of anti tics and when labour is prolonged the practice, lowed by Charles, of plating high vaginal abs within twenty four hours of rupture of the mbranes seems sensible It is generally agreed at administration of antibiotics is not indicated in e "latent interval" between spontaneous rupture the membranes and the onset of labour Eastman[21] marks that in his series intensive antibiotic therapy roughout this latent period neither prevented trapartum infection nor affected perinatal mortality

Systemic Lupus Erythematosus

The diagnosis of systemic lupus erythematosus as become so fashionable that physicians can be rgiven for thinking that it is a newly distinguished ndition But this is not so sixty years ago ir William Osler[22] described almost all aspects f the varied clinical picture that we now recognise arvey et al.[23] have lately reviewed this disorder at ngth and have described 138 cases seen at Johns opkins Hospital, Baltimore

In systemic lupus erythematosus skin lesions may s Osler recognised) be absent, or they may consist f the well known "butterfly" erythema on the face r a discoid lesion, and the course varies from acute and hort to chronic and lasting many years Harvey and is colleagues agree with Arnold[24] and Haserick[25] ho use the term "systemic lupus erythematosus" r the generalised form of the disease, and the terms discoid" and disseminate" only for the skin sions They suggest that the clinical picture varies much that it is useless to classify the disorder into stinct types Like others they found that most of eir patients (78%) were females 80% were aged 5-40 years In no less than 55 out of 105 cases that ere carefully analysed allergic manifestations, such s urticaria or hay fever or sensitivity to various rugs, were recorded but in only 20 of these cases did uch manifestations appear before systemic lupus was iagnosed. Harvey et al list twenty four diagnoses ade by various physicians in the early stages, hey fall roughly into the groups pyrexia of unknown rigin," rheumatic diseases blood diseases skin iseases, diseases of the central nervous system and functional illness In the 105 cases that were nalysed the initial manifestations were related most ommonly to joints 34 were diagnosed as acute igratory polyarthritis' and 16 had arthralgia ever was the leading sign in 24 patients and some ort of erythematous skin lesion in 21 fatigue and eakness were the main complaints in 18, weight ss in 7, other initial symptoms were much less ommon As might be expected in the course of the sease most patients showed weight loss skin lesions, and joint disorders, and 65 had some abnormality of the urine What is more surprising is that 78 patients had a hæmoglobin level below 11 g per 100 ml and 26 had thrombocytopenia, 56 patients had pleurisy, 16 with effusion, as many as 45 had pericarditis Enlargement of lymph glands was detected in 58 patients, this was generalised in 34 Splenomegaly was found in only 15, but the liver was enlarged in 32 Analysis of skin lesions showed that a "butterfly" rash had been present in 39, mucosal lesions in 14, and a purpuric rash in 9 In 27 patients a "typical rheumatoid arthritis with deformity' was recorded The thrombocytopenia of systemic lupus erythematosus may be indistinguishable from the "idiopathic' form, and a full increase in platelets may follow splenectomy, nor does the microscopic appearance of the spleen given any guidance The platelet-count remains high until the patient ultimately dies from the other effects of systemic lupus In the Johns Hopkins series a useful clue in 6 cases, was that discoid lesions preceded the purpura, but in others there was no preliminary sign. It is no wonder that Harvey and his colleagues say that "the disease may appear with a confusing array of manifestations resulting from multisystem involvement in which it is difficult to detect any obvious continuity Joint and, with somewhat lesser frequency, mucocutaneous manifestations are commonly present in episodic fashion and are helpful in pointing towards the correct diagnosis"

With so complex a clinical picture, it is not surprising that physicians turn to the laboratory for help in diagnosis The "L.E cell phenomenon," originally described by Hargraves and his co workers in 1948 is the basis of the most useful test for confirming the diagnosis[26] The phenomenon is now known to be due to a plasma factor associated with the gamma globulin fraction. With proper technique it can be detected using only the patient's own blood, no bone marrow or normal polymorphs are needed Harvey et al use heparinised blood from the patient and examine the buffy coat. They think that other techniques, especially those using clotted blood, are more liable to give false-positive results They obtained positive results in 82 out of 96 patients known to have systemic lupus erythematosus whose blood was examined and in a group of over 700 patients with clinically similar skin, joint, blood, and other symptoms due to various other diseases, there were no positives at all Another laboratory test that has been helpful is examination of the plasma proteins Of the 105 Johns Hopkins patients 58% had serum globulin levels of over 3 g per 100 ml., and values in excess of 4 g per 100 ml. were not unusual In half the patients albumin amounted to less than 3 5 g per 100 ml, and in some it was lower than 2 g per 100 ml. The plasma fibrinogen level was found to be increased in every case where it was tested Electrophoresis also showed high fibrinogen and high gamma globulin levels Other plasma protein tests have given results that are too variable to be useful Biopsy of lymph nodes skin, and muscle, though it has been widely practised seldom yields a pathognomonic picture Thus in Harvey's group of patients lymph node biopsy was inconclusive in 11 and positive

in only 2, of 19 skin biopsies 12 were positive, and out of 12 muscle biopsies only 1 was positive

No fewer than 34 of the patients who had *not* been treated with hormones had remissions lasting at least a year, in most of these patients the remissions lasted one to four years, but some were free of signs of active disease for ten years or more 12 patients had more than one remission in the course of their illness Commonly the remissions affected only some aspects *of the disease, and complete relief with return to full* activity over a period of years was unusual Administration of corticotrophin or cortisone is now the treatment of choice 62 of **Harvey**'s patients were treated in this way After this treatment was discontinued the disease remained quiescent or mildly active in 26%, in a further 18% quiescence persisted with maintenance treatment, in *the disease continued to progress* 18 patients (2 died, 9 of them during treatment **Harvey** and co workers point out that corticotrophin and corti are not specific remedies, and they agree with and **Bader**[27] that the best that can be expected that some patients will be maintained in remission some time The difficulty in treating systemic lu with cortisone or corticotrophin is that car vascular complications often develop, this happ in about half of the patients treated, but Har et al point out that these complications can controlled and do not regard them as a indication to continued administration

Annotations

TRAINING THE NURSE

In nursing experiments are in the air—some of them, perhaps, too much in the air Several of those suggested by the Scottish Standing Nursing and Midwifery Committee,[1] however, seem well worth trying After the publication, in 1953, of the Nuffield job analysis of the work of nurses in hospital wards,[2] the standing committee appointed subcommittees to examine that report in detail and make recommendations This report is based on their findings Among other things the standing committee suggest an experiment in two year training, and another in a three year comprehensive training The two-year course, they say, might be tried for five years to assess its value The student nurses should, if possible, live in a building, separate from the hospital, where they should receive their theoretical teaching and develop their corporate life—a sort of college, in fact From this they would go out to appropriate hospitals in the neighbourhood, for their ward training The students would be carefully selected, of good secondary school standard in education, and not younger than $18^1/_2$ The annual intake would not be more than 30, and the teaching staff would include not fewer than 3 sister tutors and 2 " clinical instructors "—a new grade of teacher, having the status of ward-sister but with some training in teaching, who would give them their ward instruction We have always believed that a two year training course would be possible for nurses, provided they were given proper student status—as in this experiment they would be The committee foresee that the curriculum might cover a wide range of subjects, including medical, surgical, gynæcological, psychiatric, pædiatric, ophthalmic, dermatological, and obstetric nursing, communicable diseases (including tuberculosis), operating theatre and ear-nose and throat work, experience of outpatient work, and domiciliary visiting The whole course would be designed to link the theory and practice of nursing in a logical manner—an experiment which we should dearly like to see tried

The committee have also considered the possibility of a three-year course, to be conducted in a hospital or group of hospitals already training nurses The student nurses would gain experience in general nursing and also, for *short periods, in special fields including mental disorder*, infectious diseases and tuberculosis, sick children, and public health The committee say that student nurses on this course would need "to be given student status to a greater degree than is given to student nurses now" but they clearly do not contemplate giving them the full student status suggested for those taking the two-year course The chief advantage of this plan to be that it would bring the student into touch aspects of nursing which at present she may encounter in general training It is disappointing, ever, that the committee have not included, these, geriatric nursing or the care of the chronic

Another important recommendation is that the method should be tried—the patients in each ward divided into groups of about a dozen, and each being assigned to the care of a small team of nurs team would normally consist of a staff nurse, a training, and a nursing auxiliary, and these them would attend to all the needs of the patients care Such group assignment of patients has ofte advocated, and some experiments have already made by now reports on them should be available system has many advantages—the chief one bein the nurse comes to think in terms of " patients," of " rounds " of this or *that type* of duty It also weaknesses, one being that off-duty times and interruptions oblige all the nurses in the ward after all the patients some of the time, instead of the nurses looking after some of the patients all time The committee have sought to overcom difficulty by providing a relief team to take ove group of patients in turn, so that all the membe team are off duty together, but they admit that t for a fairly lavish supply of nurses They reco that special funds should be found for an expe on these lines

Their proposal for the creation of a new grade—"clinical instructor" already mentioned—perhaps d rather cautious consideration They argue that sisters have not much spare time, and that most o have had no training in teaching They therefore that a nurse who has spent two or three years as nurse and has taken a course—of about six wee teaching should be able to instruct students in wards in nursing techniques Two people may ably object to this suggestion the ward siste might not welcome the entry of another woman o status into her domain, even though her righ responsibilities (as the committee insist) wou amply protected, and the sister-tutor, who i qualified to give clinical instruction but seldom a to put her nose inside the wards A more w appointment would surely be that of a coordina studies, whose main task might well be to reconcile sisters to the thought of a ward round conducted sister-tutor In any case, clinical teaching should be given by a senior person—whether ward sister or tutor—rather than by a nurse still considering w or not to take a higher qualification What the sister needs is time, and what the sister-tutor ne access surely these could be provided without the duction of a new grade of teacher who might affront

I N N

IT is no easy task to find suitable "official" names for new drugs. The W.H.O. Expert Committee on the International Pharmacopœia, which aims at obtaining international coöperation in the selection of such names, proposes[1] that the initial letters I.N.N. (international non-proprietary name) should be inserted after the name of the drug where this is internationally approved. The committee suggests that the naming authority of the country in which a drug originates should bear in mind the principles on which an international name is selected: this should ensure that such a name will prove internationally acceptable. The name should be short, it should avoid confusion with other drugs, and it should give some indication of the principal chemical groupings, but be free from any therapeutic suggestion. Various syllables are recommended to indicate certain pharmacological groups. These include the suffixes "-ine" for alkaloids and organic bases, "-in" for glycerides and neutral principles, "-caine" for local anæsthetics, and "-stigmine" for anticholinesterases.

National naming authorities have already shown their willingness to coöperate by submitting some 300 proposed names to the expert committee. If only international collaboration of this order had been achieved half a century ago!

ELECTROCARDIOGRAPHY AS A SCREENING TEST

A SINGLE comprehensive test for detecting heart-disease would be highly valuable, and it is hardly surprising that in the U.S.A. electrocardiography (E.C.G.) has been used for this purpose. At present its limitations seem to outweigh its advantages. Despite some evidence that lead I by itself is hardly inferior, multiple leads are generally regarded as necessary, and these cannot conveniently be recorded in a mass survey. Moreover, the criteria of normality are in doubt. Minor signs such as extrasystoles, uncomplicated axis-deviation, slurring of QRS, and T wave changes in lead III, can be ignored; but borderline prolongation of P-R, QRS, and Q-T, and flattening of the T wave in left-ventricular leads, will often make interpretation difficult. Generous standards are obviously necessary to allow for normal variations and for changes due to age, posture, and body build. The effects of a recent meal may be important, especially since, as Levitt and Dinman[2] have shown, they can reverse pathological inversion of the T wave. Even when those factors have been taken into account, it is still not easy to assess the worth of the E.C.G. as a screening test. Graybiel et al.[3] found it useful in excluding disease in young airmen; and Philips[4] thought it the best single test for heart-disease, with a success-rate of 65% in case finding among 2250 people. Dawber and his colleagues[5] found 50–60% of cases in 2000 subjects, with little difference whether lead I alone or the twelve conventional leads were used; they also found 18% of false positive records.

Sprague[6] has proposed an electrocardiographic grading for the assessment of job fitness in railwaymen; but Durham and McGee,[7] after sixteen years' experience including the examination of 3700 electrocardiograms from 7400 industrial workers, find the electrocardiogram unhelpful in prognosis. It would be a pity if this or any other single test were allowed to justify hard and fast rules for the employment of patients with heart-disease. The prognosis of heart disease—particularly of infarction and degenerative myocardial conditions—is now known to be much better than was formerly thought, and a patient's capacity for work of any kind can be judged only by his performance. There is even evidence that exercise within limits may improve the prognosis. As Durham and McGee point out, it is the duty of those who examine workers with heart-disease to educate employers to a greater understanding of their potentialities.

PREVENTING RHEUMATIC FEVER

THE risk of recurrent rheumatic fever in a patient who has had one attack is considerable; nine years ago Hansen[1] estimated it as 60–75% in the three years after an initial bout. This risk is associated with respiratory infection (possibly mild or unnoticed) with group A streptococci, whose rôle in the pathogenesis of the disease is now undisputed. By prophylaxis this risk can be greatly reduced. Stollerman[2] has compared the effect of prophylaxis with sulphadiazine, oral penicillin, and repository benzathine penicillin. Despite its apparent disadvantages (risk of serious toxic effects and occasional bacterial resistance) sulphadiazine comes out of the comparison very well. In nearly three thousand "patient seasons" studied by many investigators the sulphonamide prophylaxis groups showed a recurrence rate 85% lower than that of the control groups. With oral penicillin results are good and serious toxicity is rare; but the minimum effective dose is not clearly established, and at the recommended level (200 000–250 000 units daily or twice daily) the cost of continuous prophylaxis is not negligible. Intermittent prophylaxis with larger doses (800 000 units daily for the first week in each month) has given favourable results,[3] but the cost would be no less. Both oral penicillin and sulphadiazine have the disadvantage that breaks are likely in the daily routine of taking the tablets. As an alternative the new repository penicillin compound benzathine penicillin, administered intramuscularly once a month in doses of 1 200 000 units, has so far given very good results; but the pain at the injection site is considerable, and it is not yet certain whether reactions are commoner with benzathine penicillin than with penicillin by mouth. Neither oral[4] nor benzathine[5] penicillin in the usual dosages significantly increase the penicillin resistance of pharyngeal strains of viridans streptococci; but with benzathine penicillin the blood level of the drug, though sustained, is very low, and does not afford protection against, for example, bacterial endocarditis.

Discussing group A streptococcal respiratory infections Stollerman rightly remarks on the importance of prompt and adequate treatment with penicillin. There is now much solid evidence that if the course of penicillin suffices to eradicate streptococci from the throat, the risk of a subsequent initial attack of acute rheumatic fever is greatly reduced.[6] Early treatment continued for seven to ten days both eradicates the streptococcus from the pharynx and suppresses antibody response to the organism as measured, for example, by the antistreptolysin test.[7] These two effects have been to some extent separated and studied in an investigation by Catanzaro et al.[8] In this American trial involving nearly 1200 cases of group A streptococcal pharyngitis in young adults a group of patients received delayed penicillin treatment, starting on the ninth day after the onset of symptoms. Control groups either received no treatment or were treated with sulphadiazine from admission The antistreptolysin response to the streptococcal infection was about the same in all the groups, but in the penicillin group the incidence of subsequent rheumatic fever was much lower than in the untreated and sulphadiazine-treated groups

If the antistreptolysin response indicates the response to other streptococcal antigens it may be concluded, as Cantazaro et al point out, "that the prevention of rheumatic fever by penicillin treatment of streptococcal disease is not related to the suppression of the immune response ordinarily seen" On the other hand, the results suggest that the living streptococcus must be present for rheumatic fever to develop although this organism has rarely been detected in the joints, blood, nodules, or heart valves of rheumatic patients These workers suggest, too, that their results make the "auto antibody" hypothesis regarding the ætiology of rheumatic fever less tenable, but knowledge of the biological mechanisms of antigenicity and tissue antibody response is at present so fragmentary that it is difficult to substantiate either this argument or the alternative hypothesis of hyper sensitivity to "streptococcal products" Nevertheless, analysis of the effects of antibiotic treatment of strepto coccal infections may yield further information on the pathogenesis of rheumatic fever

ATYPICAL TUBERCULOSIS OF THE LIVER

In patients with tuberculosis the liver may be affected in many ways, either directly as a result of the spread of infection to the liver or indirectly as a result of the metabolic disturbance Amyloid degeneration and severe fatty infiltration are the two outstanding types of hepatic disease due to such metabolic disturbance But, apart from these severe changes, impaired liver function can commonly be revealed in tuberculous patients by function tests Involvement of the liver owing to bacterial dissemination is also by no means uncommon, especially in the late stages of tuberculosis when the incidence may rise to 80% Jaundice is rare, there was only a single case in Cruice's [1] series of 570 necropsies on patients who had died of chronic pulmonary tuberculosis, and only 7 in his 1748 clinical cases of tuberculosis Tuberculosis of the liver is therefore easily overlooked in the diagnosis of chronic jaundice, especially because the clinical picture closely resembles that of infective hepatitis Since the prognosis of hepatic tuberculosis has been vastly improved by antibiotics and chemotherapy the recognition of such cases is important

Cleve et al [2] have now described 4 cases under the title "atypical tuberculosis of the liver with jaundice" This is defined as a condition "where the liver is principally or exclusively involved in tuberculous infection and where there are signs and/or symptoms of hepatic involvement" All 4 patients were Filipino men of military age The commonest clinical features were mild to moderate persistent obstructive jaundice, low-grade pyrexia often accompanied by chills, hepatomegaly, and upper abdominal pain unrelated to meals Liver-function tests suggested parenchymal hepatic injury, there was increased thymol turbidity and bromsulphalein retention In only 1 case was there evidence of active pulmonary tuberculosis, in 2 others there was radiographic evidence of quiescent pulmonary disease It is not surprising that the correct diagnosis was made only with the aid of laparotomy, even then in the 1st case the raised white hepatic nodules were mistaken for metastatic neoplasms until histological examination revealed the characteristic changes and acid-fast bacilli Laparotomy is apparently the only certain method of confirming the diagnosis, which cannot be reliably excluded by a negative Mantoux reaction or by repeatedly needle-biopsies

Treatment with streptomycin 1 g daily has prod some dramatic results Of the 4 patients treated in t way by Cleve et al 2 apparently recovered comple seven and twelve months after the end of treatm An equally satisfactory result has been reported i other cases [3 4] Atypical tuberculosis of the liver jaundice is undoubtedly a rare condition in this c where the resistance of the viscera, excluding the l is high In other communities visceral suscepti may be much greater, and Cleve's series of 4 cas Filipinos suggests that racial factors may be impor

USES AND DANGERS OF CHLORPROMAZINE

Two further uses for that versatile chlorpromazine, have been described Tilley and B claim that in 3 cases of neurodermatitis it consider relieved pruritus and motor overactivity Friedgood Ripstein [6] gave chlorpromazine to 8 drug addicts abrupt withdrawal of their drug (morphine in 5 insta pethidine in 2, and pentobarbitone in 1) No p experienced withdrawal symptoms, and the for the drug of addiction was abolished

It is not surprising that chlorpromazine, which wide range of activity, should exert toxic effects A hypotension is not uncommon, especially when the p is allowed to remain on his feet during the initial of treatment with large doses, and deaths have resu from this complication [7] Several cases of jaundice also been reported,[8–10] and this complication too been fatal The jaundice is peculiar in usually appe to the clinician to be obstructive, biopsy spec have shown intrahepatic biliary stasis [9] or per cellular infiltration [10] Blood changes occasionally ar notably eosinophilia,[9] though agranulocytosis has recorded [11 12] and in 1 case this was fatal [11] These other possible hazards of chlorpromazine therapy sh prompt the clinician to examine critically in every the indications for administering the drug Repea exposure has led to severe dermatitis in nurses [13]

AN EXPERIMENT IN
PROPHYLACTIC PSYCHIATRY IN CHILDREN'S HOMES

W LINDESAY NEUSTATTER
M.D B.Sc. Lond. M.R.C.P
YSICIAN IN PSYCHOLOGICAL MEDICINE ROYAL NORTHERN
SPITAL, LONDON CONSULTING PSYCHIATRIST THE L.C.C.
SCHOOL HEALTH SERVICE [1]

THIS paper describes what has so far been done wards creating a prophylactic psychiatric service in e residential establishments of the London County uncil. After six years the practical issues have clarified emselves and an account of them may help anyone io is contemplating, or might contemplate a similar heme

The L C C has 6 residential schools for deprived ildren accommodating about 2500 children of both xes, and 8 small family homes for 200 There are also nurseries and nursery schools, 4 approved schools, 6 hools for the educationally subnormal, 5 schools for e maladjusted (with another 3 opening shortly) 12 hools for the physically handicapped 2 schools for the nd, 2 schools for the deaf and 7 short stay schools for e delicate. This gives a grand total of 5380 children its care in various residential establishments and in dition there are 2 reception homes and one reception ntre with a total annual turnover of 650 [2]

Most of these children are in the council's establish ents because of home circumstances—e.g parental ness divorce, or neglect Hence there is an especially olific field for psychiatric disorders Also although is nominally a specific handicap such as intellectual tardation or organic disorder which is responsible for mission to residential schools for the educationally bnormal or the physically handicapped, in fact the ild is not infrequently in such a school because of home cumstances or an element of maladjustment Thus all idential establishments contain children some of whom least are maladjusted.

The National Health Service is concerned with pro- ling specialist therapeutic services, based on hospitals eatment being their concern the L C C set up what y hope will become a prophylactic psychiatric service part of their public health activities To this end they ve appointed psychiatrists to advise the staffs of resi ntial establishments on child psychology in general. is does not preclude—and, incidentally inevitably led —advising on individual children but formal treat nt of individual cases is considered to be a responsibility the N H S Any children needing such treatment are ferred to child guidance clinics or hospitals

The first step in establishing the new service was my pointment in 1947 as a part-time consulting psychi rist The duties were then largely advising on the ucture of the service so as to pave the way for its work 1949 a full time psychiatrist the late Dr H G illiams, was appointed and on the experience gained e service was later enlarged by appointing three more rt time psychiatrists whose sessions were together ual to those of one whole time psychiatrist In addition r whole time psychiatric social workers have been pointed mainly based on the maladjusted schools an ential duty which they undertake is preparation of e home for the return of the child

At Bredinghurst Maladjusted School a lay psycho erapist is employed for 11 sessions per week In 1948 Mr H A T Child was appointed senior educational psychologist and advises on technical educational problems

THE PSYCHIATRIST'S RELATIONSHIP WITH THE STAFF OF ESTABLISHMENTS

The first step in a scheme of this kind is the acceptance of a psychiatrist by the staff, for psychiatrists are by no means always persona grata They are viewed, at best with suspicion and when besides being psychiatrists they descend from County Hall the reaction to them is distinctly guarded. My first task therefore in 1947 was to try to overcome this resistance Here a psychiatrist's training in listening proved valuable, and at initial visits I did little more than listen One's reception was always friendly enough, and a measure of receding suspicion was the production of time honoured stories about ' trick-cyclists ' Next there would come heartfelt and understandable complaints of the inordinate time it took to get a child to a distant clinic or the interminable waits there—of a member of the staff being thus occupied all day " and then they see the child for a quarter of an hour and send a report telling us what we told them ! "

At this stage the headmaster usually observed how glad he was to have a psychiatrist visit ' only I fear you won't find enough cases here to make it worth your while doctor " This last remark needed to be accepted with some caution Almost in the same breath one headmaster (now retired) pointed to a small boy passing the window and said : He might interest you doctor he has twice tried to set the place on fire ! " A study of the headmaster's psychology is valuable and a tactful reference to the merits of Hutton or Graveney if the headmaster comes from the appropriate county can establish better relationships than many a dissertation on psychology It is very important to try to overcome the common suspicion of the psychiatrist some of which is understandable Those with years of first hand experience of youngsters are naturally apt to resent intrusion of someone who they feel is trying to teach them their job and in dealing with behaviour problems teachers and house staff undoubtedly have practical experience of handling children which psychiatrists lack I have been impressed by the very good understanding of problem children which some of them have shown On the other hand some staff feel that they have a knowledge of maladjustment and child psychology which they do not in fact possess They are not always as aware as the psychiatrist that the ultra good child may be a more serious problem than the disturbed one Some indeed have closed minds and are quite unreceptive to new ideas

Where specific disorders such as hysteria psychopathy early schizophrenia or epilepsy exist, the psychiatrist obviously knows more about these conditions than the layman and this the staff will readily allow Moreover in my experience if one starts by confining oneself to advice on these medical matters where one's authority is acknowledged one's opinion in other spheres will afterwards be more readily accepted

Williams (1953) and Prince (1953) have emphasised that often it is not formal advice which the staff want so much as moral support Prince points out the importance, in schools for the maladjusted of reassuring teachers that only limited success can be hoped for with their difficult charges and of making them accept philosophically the fact that parents of maladjusted children are ipso facto, neurotic and cannot be expected readily to change their stays

Williams also writes of the need to allow individual members of the staff to abreact by discussing their personal difficulties This relief of their feelings can result in greater tolerance of some of their very difficult charges The changed attitude is the outcome of an emotional and not an intellectual reorientation

---

[1] The views expressed in this paper are entirely my own and should not be attributed to the London County Council.

[2] Until recently the L.C.C. was also entirely responsible for their Remand Home psychiatric service Now as with child guidance clinics the L.C.C. supplies the building and ancillary staff only

Cooperation with the visiting school doctor was always attempted With a busy practitioner this could prove difficult, but he receives copies of psychiatric reports

SEEING THE CHILD

Having established contact, the next question was how best to get full value from the psychiatric services It is possible either to confine one's activities to discussion with the teachers, *without* seeing individual children, or to see the children as well I unhesitatingly favour the latter method, on the following grounds

(1) Psychiatry is a highly controversial subject, and, purely theoretical discussion of problems may well increase rather than diminish suspicion of the psychiatrist In any case discussing children's problems in the abstract always leads to questions of how a particular child should be handled To advise without seeing the child can be very misleading, because the teacher's account may differ substantially from what would be one's own impression Even after examination one's advice may be incorrectly interpreted, and to advise theoretically involves additional dangers

(2) The psychiatrist is trained to look below the surface and to understand unusual reactions He should thus be able to give something tangible and useful to the child, even though the interview is not primarily therapeutic

(3) Not seeing the child tends further to separate psychiatry from general medicine If a child has a bad heart the doctor is expected to examine him, not to give a dissertation on cardiology The same should hold good for a psychological disorder

Thus I have always made a point of seeing the child, and so have my colleagues This does not preclude discussion in general terms of points of interest with the teachers, and, as one is not treating the children, such discussion is particularly important Indeed, I have given a number of formal lectures which have led to quite a lively discussion, but have also inevitably led my being shown children who the staff feel exhibit some of the traits referred to

I have preferred to give descriptive talks in non-technical language on the "medical" aspects of psychiatry referred to above, rather than embark on psychopathology There is enough in the former to a interest and lead to discussion on different psycho types, while it avoids the opposition and incredul which the more complex expositions of psychopath are apt to be met, the simpler aspects of the b —e g, boastfulness being an overcompensatio feelings of inferiority—are sufficiently well recog nowadays not to need formal presentation

NUMERICAL SUMMARY OF FINDINGS

The accompanying table is founded on returns by the various psychiatrists over a period of a The figures refer to the number of children seen with various disturbances noted, on each occasion If the same child was seen repeatedly it was entered time, and the figures therefore exaggerate the a number of children of one type seen in the year

As the returns were made for administrative pur and not for research, the terms used were unfortuna not standardised, and it is evident that different t were used to express the same disorder, thus be disorder and maladjustment seem to have been synonymously so often that I have felt justified in the two together as "total disturbed behaviour" W several different descriptive terms had been used ("backward and aggressive") it was hard to know w one to choose I took the first one, which may weighted certain of the findings Thus in smaller backwardness was a noticeable feature, yet as often due to anxiety, it could have been tabulated as

In some cases behaviour disturbances were su into more detailed categories, but exact numbers fallacious because everyone did not use these terms in column 1 (physically handicapped) the numbers so small that the percentages must be viewed with caution

It will be seen that disturbed behaviour was b the commonest cause of referral, presumably attracts attention most readily Backwardness nervousness come next most frequently, the figures not sufficiently accurate to show valid co between the groups

SUMMARY OF FINDINGS OVER 12 MONTHS

Kinds of School

RESIDENTIAL SCHOOLS FOR DEPRIVED CHILDREN

The length of stay in these is determined by outside cumstances, and is not as in 'special' schools for fects, dependent on the response of the child. This ates special problems, because the children may have acclimatise to continuous boarding-school life. One of great difficulties is the large numbers (sometimes to 50 children) in one house which prevents house rents from giving the children the amount of individual ention they would like to give, and which the children ed Also with so many charges they may under ndably find it hard always to show the necessary tience with children of difficult habits, such as enuresis As always, the exceptionally sensitive child whose aladaptation is not obvious tends to be overlooked. erefore the child most needing psychiatric attention often not recognised nor is it easy for the over rdened house-mother to give it the considerable time eeded when it is. The psychiatrist's task is to try to ntify these children and find the best way of securing e special handling they need—a task which is not easy e real solution is outside medical hands since it involves oney, bricks and mortar, and personnel suitable for ese extremely arduous duties

APPROVED SCHOOLS

Apart from the difficulties arising from the high oportion of boys of inadequate intelligence one of e chief problems met in approved schools is the esence of a small number of 'abnormal' offenders ost children in approved schools are not deep psycho gical problems their offences are more readily plained as commonplace reactions to temptation and d influence But in some the delinquency appears more a form of neurotic behaviour—an unconscious expres n of conflict, as in hysteria or compulsive acts The actions of the former are straightforward they are at would be expected particularly in not very intelli nt children or those of weak personality who have ccumbed to bad environment Such types respond to stable atmosphere and to a regular routine and disci ne but the latter often need a freer atmosphere in ich to work out underlying feelings of guilt and hos ty It can be seen therefore that their correct handling an ordinary approved school is very difficult Making ceptions for a few children in a large school leads to vious difficulties

The recognition of children who have been wrongly ced is clearly a function of the visiting psychiatrist. no means all of them need moving elsewhere for itable steps can be taken within the school if the child's ndamental attitude can be gauged The child who els anxious or inferior may have put on a brave face fore the staff but is willing to reveal the true state of fairs to the psychiatrist He in turn can pass the formation on to the staff In one such instance, where boy was very unhappy and had come from a bad me I was able to advise the headmaster who promptly troduced the boy to his dog which proved most effective erapy

Homosexual problems though not peculiar to approved hools are prone to occur in any residential establish ent where the sexes are segregated There is no ready ade or easy solution; but the psychiatrist can do uch to allay the anxiety of the headmasters who el such happenings in their schools may lay them open criticism, and can help the staff to keep the problem perspective

Where cases of sexual practice have arisen I always ink it best for the school doctor or the psychiatrist ther than the teachers to take the matter up with the y Treatment especially when intelligence is low is likely to succeed and the best practical expedient is to send boys with marked homosexual propensities to one school, where the staff have special experience of them and can keep a better watch on their activities.

The value of corporal punishment is a controversial point It is but sparingly used at the approved schools I visit but even the head of a maladjusted school where he has never used it, contended that the right should be there, if only because the substitutes might be subtler and more unpleasant. He felt strongly that it should be left to the teacher's discretion The counter argument is that where the teacher's judgment is good, as with this very headmaster, corporal punishment is not used, but where the teacher's judgment is bad there is a danger that the very boy it may most harm will receive it, because he is the one the teacher least understands Thus at a public school I saw a withdrawn lad who had an L C C scholarship and was proving a complete failure both at work and at fitting in with the others His housemaster remarked that had he not heard he was a "psycho case he "would have beaten him regularly Such an attitude makes "psychos" very dubious about beating being left to the teacher's discretion If, as has been suggested in certain institutions, beating must be sanctioned by the medical officer this puts the doctor in a false position which must interfere with his relationship either with the staff or pupil and abolition would be the best solution But one very real difficulty in avoiding corporal punishment is that so many of these boys have been beaten at home and would fail to understand other methods Incidentally, in regard to the supposed deterrent effect of a good thrashing on delinquency I cannot say whether this has stopped potential delinquents, I can say that I have seen many boys who have been "belted repeatedly at home without any noticeable effect in preventing further transgressions

MALADJUSTED SCHOOLS

Under the 1944 Education Act maladjustment, like educational subnormality or physical handicap is regarded as a disorder requiring treatment by special educational measures In fact, however, its place seems to be rather within the province of psychological medicine and our psychiatrists have accordingly visited these schools not less than once a fortnight and sometimes weekly (see table) There are not more than 50 children in any of these schools and the amount of freedom the children are allowed depends largely on the character of the headmaster

A question of interest is whether formal psychotherapy is needed Some believe there is no need for it in children at all while others think it essential in all cases. In a small experiment on 19 boys at Bredinghurst School by Williams (1953), using improved social relationships and learning capacity as criteria, he found a significant difference favouring the treated versus the untreated group The experiment was open to the usual criticisms of such small surveys involving subjective estimates but is an interesting pointer

Formal psychotherapy apart, in my view a troubled child needs the opportunity to talk about his worries and express his feelings, just as an adult does Contrary to popular supposition this can be done without any need to use complex language to encourage introspection or to make the child feel he is a 'case' Whether such talks are held with a psychiatrist psychologist, or schoolmaster is largely immaterial—except that the latter who may subsequently have to be an impartial disciplinarian is worst placed for the task What matters is that the listener should be objective sympathetic and preferably sufficiently queer himself to understand unusual children—which perhaps puts the psychiatrist ahead of the others! He should also be able to remember enough about his own childhood to see the problem from the child's standpoint This does not necessarily imply agreement or approval, and he may have to explain that it does not But disagreement does not matter provided the child feels that its point of view is being understood and not just overridden

E S N SCHOOLS

At schools for the educationally subnormal the problems are parallel to those in other residential schools, though they are more difficult to deal with on account of the low intelligence of the children When one remembers that child guidance clinics will rarely accept children with an I Q below 70, one realises the difficulties with which these schools have to cope

Children in E S N schools may be maladjusted dullards, whose emotional difficulties have resulted in such an inability to learn that they have had to be dealt with as E S N children, but they are really a variety of maladjustment I have been impressed by the improvement of young unstable E S N children in small residential E S N schools

Occasionally, one sees children who are so emotionally disturbed as to be quite unapproachable and untestable, and have to be ascertained as E S N even though one suspects they are not

An example of this was a pitiful terrified girl of 8 whose mother, a backward unstable woman living with a man, not only knocked the child about but punished her by locking her into a small dark room by herself In the course of a year at a small E S N school, with kindly treatment, she improved considerably, and turned out to be only dull and not E S N

NURSERIES AND NURSERY SCHOOLS

Experience in these has been limited to a year, and willingness to accept the psychiatrist has varied more than in any other establishments The visiting psychiatrist, Dr E Huband, reports that the problems she has met fall into three groups

(1) Fundamentally normal children reacting in a disturbed way *as a result of past bad experiences, or inability to adjust* to nursery routine There, she felt, the psychiatrist could do much by seeing these children and advising on their management

(2) Children who are so abnormal, emotionally or intellectually, that merely *advising is* of limited value Ideally they need different placing

(3) Seriously maladjusted children in need not only of special placing but of actual psychiatric treatment

The outstanding impression has been that visits were too thinly dispersed to make very much progress For the present, policy has switched to seeing the effects of visiting a few of the institutes regularly, and as yet no information is available

PHYSICALLY HANDICAPPED SCHOOLS

The problems met with in children in these schools fell into three groups

First there are psychological difficulties due to an unsatisfactory home situation These are similar to those found elsewhere, but the physical defect is sometimes the cause of parental rejection, particularly if it is disfiguring

Thus a pathetic little girl of 10, with severe congenital heart-disease, was disturbed in her behaviour Her parents mostly lived abroad but even when the mother was in England she never visited the child The child told me she really did not mind as her mother used to call her an ass and a fool when her dyspnœa prevented her tackling a strenuous task.

Secondly, there are cases where feelings of inferiority arise from physical defects, especially where deformity exists

A spastic girl of 12 spontaneously referred to a cardiac case as "lucky" because she looked normal

Sometimes hysteria exaggerates a disability One very int [illegible] girl of 14 was clearly not using her partially [illegible] hand and leg as much as possible, because she preferred to try to ignore her disabilities Again, a child
a marked spinal bifida was incontinent because she
make no effort to go to the lavatory. She, too, seem
prefer to pretend that nothing was wrong

In contrast to these cases, it is gratifying to be ab
record how many of these crippled children I saw
happily in their free time, even quite severely par
boys playing a good game of table tennis

Thirdly there are the cases where physical defect
psychological difficulties are intermingled

For example, a child with kernicterus showed consid
symptoms of anxiety She was always on edge and s
trying to please, almost profusely so She had queer dr
many of which were connected with punishment Sh
dreamt frequently of a boy friend, aged 10, at another s
and of her father kissing her in bed, a thing he had never
She *repeatedly made drawings of animals with curious*
which, she said, were part of somebody's body

One suspected that, in spite of her age, she had co
of a sexual nature She also had lost her favourite brot
Korea Her emotional difficulties probably added
motor instability She would have been an interestin
for play therapy but there were no facilities

It is my impression in all the cases dealt with th
children appreciated the opportunity of discussing
problems with *a doctor, and they seemed to do* so
readily than children in ordinary schools

RECEPTION HOMES AND SHORT STAY HOMES

The psychiatrist has a particularly important r
play in the reception homes, because the need for a
to be received—sometimes very suddenly—into c
itself an indication of a family situation likely to
produced a disturbed child The future welfare
child is very dependent on correct placement, an
task is taken very seriously, usually being settled
conference between the psychiatrist, the psych
social worker, the care committee, and the staff
reception home

In short stay homes, one of the psychiatrist's du
de ascertainment, for quite often children, while
ing placement in a maladjusted school, recover n
through being away from home in a stable environ

Discussion and Conclusions

One of the perturbing questions put by sceptics-
usually resented by psychiatrists because there
reply—is "what proof is there that psychiatric treat
of children yields results, and above all that it pre
later psychiatric disorders?" Figures unfortun
have not proved anything in regard to the latter que
and little in regard to the former, and one has t
back on clinical impressions—an unsatisfactory expe

In the present survey the same difficulties arise
figures given furnish no proof that the psych
services described are in fact preventing future psych
disorders Nor could anything short of an enor
research project *be expected to yield statistical* re
Therefore, one must be content to adduce argum
suggesting that the scheme described here is serv
useful function The following can be said

(1) It seems logical to have a psychiatrist to a
on psychological disorders in the same way that ca
logists or ophthalmologists are employed

(2) The psychiatrist does not exclusively advis
child management as is sometimes supposed His sp
training allows him to recognise certain syndromes—
psychosis, or epileptic disturbances—which the lay
would not recognise As Peter Scott (1953) points
correct sorting of cases is an important functio
psychiatry in the field of delinquency The same ap
to the little-charted seas still to be explored in a se
such as this

(3) The psychiatrist, even at a diagnostic interv
can give the child something tangible in his capa
of an impartial listener unconnected with discip

casionally a child acknowledges this, with a phrase ch as I find it easier to talk to you' This unburdening n be of value.

(4) In such a scheme as this the psychiatrist fulfils the ry important rôle of the doctor in any society he n advise even if he has no specific remedy and he can lieve anxiety In institutions the latter can be of great alue In backing a headmaster where serious offences abnormalities have to be dealt with in giving a acher a chance to unburden himself and in suggestions mere discussions on handling difficult problems, he n take some load off the staff, and this lightening of eir burden is likely to lead to better handling of ifficult children

The whole tenor of modern social services for children to try to avoid the unhappiness with its warping ffects, too often associated with institutions in the past n so far as they achieve this there will be better emotional development for happiness is a most important ngredient in the growth of a healthy mind

Summary

A growing psychiatric service aiming at prevention of uture instability, for children in L C C residential stablishments is described As yet no direct evidence of prophylaxis has emerged or could be expected to have merged, but arguments are adduced that the service dds to the happiness and welfare of the children and hus should assist healthy emotional development

In conclusion acknowledgment should be made to the follow ng for their parts in inaugurating and running this service Dr Leonard Browne alderman of the L C C Sir Allen Daley then M O H and Dr A. W Petrie adviser in mental health, at the start of the service; and Dr J A Scott, present M.O.H for the county of London. I wish to thank the latter for permission to publish the material contained in this paper, and all those who have coöperated in this experiment too numerous to mention individually

HEALTH IN SCOTLAND IN 1954

'THERE is no simple and satisfactory explanation of the fact that better disease control saving of life and improved environment are still accompanied by heavy sickness incidence' With this provocative statement the report of the Department of Health for Scotland[1] sums up the situation in 1954

On the credit side there were fewer deaths in child birth and from tuberculosis than ever previously recorded, as well as a continued improvement in the death rate among pre-school children Nevertheless the incidence of sickness, measured by visits to hospitals and to doctors remained heavy During the year there were more than 2 million new hospital outpatients outpatient attendances totalled nearly 7 million, and nearly 500 000 inpatients were discharged.

A disquieting feature is the persistent rise in the death rate among men aged 50–64 In men aged 55–64 deaths from respiratory cancer in 1950–52 were six times as common as in 1931 coronary thrombosis was six and a half times as common and bronchitis had increased by nearly a quarter (The death rate among females on the other hand, was in all age-groups lower than twenty years ago)

This urgent demand on the curative services has been partly met by expanding the hospital accommodation and by enlarging the hospital staffs By the end of 1954 the number of staffed beds had been increased by 9% over the figure for 1948 the number of hospital nurses had risen from 19 000 to 24 000; there had been an appreciable rise in the number of consultants and senior hospital medical officers; and the annual running cost of the hospital and specialist services had increased from £24 6 million in 1949–50 to £30 2 million in 1953–54 Even so, these increases were small compared with the increase in the number of patients passing through the hospitals

As regards the future, the report is optimistic, expressing the view that the massive amount of work now bein done by the health services will in the long run, prov valuable 'in forestalling the development of seriou disease and preventing the onset of complications.' Ultimately therefore, there will be evidence of reduction in this burden of sickness and of continuin advancement in general standards of physical health an well being'

The Widdicombe File

XXIV THE CLOUDED CRYSTAL BALL

DEAR WHIDDON

I liked your nephew Whatever branch of our profession he chooses, he has some natural advantages He i sound in wind and limb he has done his military servic and avoided marriage he answers questions diffidentl but explicitly his nails and collar are clean His wis to become a pathologist is not as for some of us, a secon choice forced upon him by the fear that he will no succeed in some other preferred way of life Until abou six months ago in Singapore he had no clear idea of wha he wanted to do One afternoon—a time he usuall devoted to repose—his familiar guided his feet to th laboratory and prompted a brother officer to invite hi to look down a microscope I would like to think that th fable of Ross was repeated—that the sight of a malari parasite in all its beauty was the occasion of somethin akin to revelation which pointed out the path of h future life At any rate the laboratory became a habit he learned a little, and he was told that a living might b made that way

I do not see him in academic life His intellectu ability is no more than average and his training in pu science up to a bare pass standard I may be wron Perhaps he will find a secluded niche where he ma learn more and more about less and less ad infinitum. hope not for there are few of our colleagues so much t be pitied as the professors *manqués* too old to sack an too inert to go But I did my best to impress upon hi the value of starting his career in some humble appoint ment in a university department Having to instruc others who know only a little less than he does will teac him his pathological A B C better than anything els If he does not know or cannot find he will be surround by polymaths who can resolve his doubts There will b a library, and if he is lucky a few feet of bench whi he may call his own Above all, he will live in an enviro ment where the main purpose of existence is the enlarg ment of human knowledge (although few of the inmat would like to admit it)

A year or two in this rarefied atmosphere may tax hi stamina but it should leave him something more than craftsman in his trade and with a better idea of what h wants to do

I suggested that he will probably become a clinical pathologist and as I began to expand upon the charms of the life which has kept me from starvation for twenty five years, I was like a Victorian clergyman stricken by DOUBT For to tell the truth I have been thinking for some time that clinical pathology as I know it today is a dying trade It is after all, a hodgepodge of activities which have only this in common—they are done at the laboratory bench If one stroke of the Presidenti pen were to strike off the Register all clinic you surgeons would be inconvenienced nature of your practice would be unch lesser breeds without the law manage to muddle along without our help, and their bills of mortality do not suggest that the effect on medicine is disastrous

When I began, I was the one and only assistant to Diogenes, and we were helped by a man and a boy We "did blood-counts", we cut up the dead, without much understanding we made simple biochemical estimations The work grew, went on growing, and continues to grow—with two results The last of my colleagues who are equally learned (or ignorant) in hæmatology, biochemistry, bacteriology, and morbid anatomy is on the verge of retirement The modern laboratory is a more or less integrated clutter of specialised departments The other result of our trade boom has been the lavish engagement of technical staff until they outnumber the doctors by five or more to one These are, moreover, of a quality outside our dreams of twenty five years ago Unless they present some evidence of higher education we will not look at them Their own examinations are stiff almost beyond reason and a B SC or two among our staff is no matter of note Are you surprised that the counting of red cells and other such chores which used to adsorb nine-tenths of our time are now done almost entirely by the technicians? Helped by better methods and mechanical devices they do them as well as ever we did and a good deal faster

How much use can be made of this galaxy of talent depends, I think, less upon us pathologists than upon you and your colleagues in the wards If you wish to know the level of molybdenum in a patient's blood—I have had dafter requests than this—the problem is a purely technical one There can be only one answer, expressed in microgrammes per 100 ml I believe that it is true of most of the problems which reach our departments of biochemistry and hæmatology that if you can frame the right question the technician can give you the correct answer If, however, you are worried about a patient because his urine is green in the morning, red at noon, and blue at eventide—a condition which you have not met before—you will need the help of a pathologist in deciding what investigations are likely to yield useful answers Some of your colleagues will want this help when faced by far simpler problems and some (oh fie) will ask for estimations of whose purpose and meaning they have no understanding at all It is this failure to ask the apposite question in everyday problems which wastes their time and mine

The weakness of the clinical pathologist's position is that medical education is improving and gentlemen with chameleonuria are rare Free from slavish toil but denied responsibility for patients, he finds that he must devote a large part of his time to helping his colleagues to frame their questions and to apply their answers He is, in fact, a sort of intellectual middleman, and that is no job for a man of parts He boosts his Ego by calling himself an interpreter of laboratory findings, but my private fear is that before long he will be looking for a job at an esperanto conference Nine times out of ten your only wish is to know if your patient is anæmic or has a leucocytosis or a raised blood urea You do not have to ask me or anyone else to "interpret" findings such as these—but neither of us showed up very brightly last Thursday on salt balances and ion exchange I comforted myself with the memory that the great and good physician to whom I clerked was never clear about the distinction between blood urea and blood uric acid And now there is a generation of physicians (and even surgeons) who think as lightly of the newer biochemistry as they do of measuring a limb or percussing a chest If these prodigies can ask the questions and apply the answers without assistance, they may be right to hint that the intervention of a pathologist between them and the technician is an old [illegible]ed formality

Now I know that we in Widdicombe are a little on our toes than they are in Hexworthy and Hoec and I believe that I am thought a useful if not an member of the hospital staff But in W C 1 I rank dimwit, and the casual gossip of a junior registr advanced Choktaw to me As medical education fc —some paces behind—the progress of knowledge, ev those doctors who practise round the sources of the will know more and more of the applications of to the art of medicine Less and less often will ther an interpreter, because they "spikka da lingo"

Having said so much I must, as usual, qualify forecast There are things done in the laboratory cannot be delegated to the very best of technician may cut and stain a section perfectly, but Daw report on the histology is a personal statement of o no different in essence from your own judgment at bedside The mental processes involved in assessing evidence on a biological problem are of a different to those needed for the mechanical estimation of defined chemical substance I doubt if the man who not seen quite a lot of the diseased human body, alive well as dead, is likely to be a very useful morbid ist In diagnostic bacteriology, too, there is more and less science than most people think, but of th have spoken before

I am no solitary prophet Some clinical patholo complain already of the "competiton" of technic and perhaps with reason Those in authority do always understand the ways of the laboratory. Th look on it as an automatic machine which, no matt who is in control, returns infallible answers to ev the most foolish questions They have never learnt th a request for an examination is made by one member the medical staff to another—or should be Abetted some of the Faculty, they have been known to favou laboratory with no pathologist in charge The sadd thing about such a place run by an unsupervised tech cian is that the doctors who use it seldom realise wh poor service they receive I think, too, that it wo do no harm if you and your colleagues would impr upon your juniors that a direct approach to the labo tory staff behind the pathologist's back is bad mann But these are only small straws in a fitful breeze So from wishing to limit the technician's field I would pre to extend it as widely as can be When he has learnt that there is to know in it, he will remain a layman, a there is still work in the laboratory for the man who l learned to recognise the infinite and individual varie of human sickness

The question which the clinical pathologist m answer for himself is the use of the leisure afforded by competent technical staff If he chooses to remain interpreter and nothing more, he must realise that it w always be a humble occupation, without responsibilit or great rewards and likely in course of time to becon as archaic as flint-knapping or woad-boiling If he fe himself to be half a physician—as some do—he will well to set himself up as a whole one, with higher degre and beds and a bowler hat There is as much call for specialist in diseases of the blood as for one in diseas of the chest and his time at the bench will not have bee wasted There is a third course open to those who sti dream of their laboratory as an ivory tower (instead the darkest, dampest, and coldest room in the hospita No one thinks seriously that looking for L E cells or doin a W R is pathology both operations are no more tha the eliciting of physical signs beyond the competence of physician Pathology is the mother science upon which the rational practice of medicine is founded and to which her offspring clinical pathology has added much of value (*Pater semper incertus*, as the lawyers say) In my lifetime I have seen the child degraded to be the Cinderella of our profession and, glass slippers being as rare as chameleon rin, the quicker she returns to mother's lap the better he alternative is an embarrassing tumble between the ed and the bench

So I would have your nephew remember that he is efore all things a pathologist When he reaches a respon ible post let him use his technical staff to the limit of heir skills He must remain responsible for their errors nd should not let any report leave the laboratory unseen nd unsigned He will not detect every inaccuracy but e should know enough to recognise improbabilities If is colleagues seek his advice let him give it freely as a age and not as a phlebotomist hired by those too idle o do their own venepunctures But otherwise his day s his own to do as he wills no operating no out patients, no teaching He may spend it writing letters o THE LANCET, or attending meetings (committee cientific, or race); or even in the quiet pursuit of nowledge A nice life

Your nephew has another advantage I hope all selec ion committees remember that anglers are classed with very honest men"—and quite right too

Yours sincerely

HARRY HAWKE

Public Health

Hygiene in Food Establishments

In a report on the health of Luton in 1954 the borough's chief sanitary inspector Mr G F Macefield, describes an investigation into the efficiency of dish washing processes in public eating places In 29 establishments—such as canteens, school kitchens hotels, and public restaurants—swabs were taken from 308 utensils, mainly plates cups, and beakers 240 swabs yielded fewer than 100 colonies per utensil (the bacteriological standard which, in the United States, is regarded as hygienically satisfactory); 10 yielded 100–200 colonies 5 yielded 300–500 colonies; 10 yielded 500–1000 colonies and 10 yielded more than 1000 colonies. But the report adds that these figures must be considered in con junction with the results from other utensils taken at the same time and on this basis it was found that quite a high standard of hygiene was achieved in the establish ments visited

England and Wales in 1954

The Registrar General publishes this week further details[1] for England and Wales in 1954 some provisional figures had already been given in an earlier return.[2] The estimated total population for the year was 44 480 000, an increase of 100,000 over the estimate for 1953. More people died from accidental poisoning, burns, and falls during the first nine months of 1954 than during the corresponding period of 1953 In the first three quarters of 1954 there were 758 deaths from accidental poisoning (658 in 1953), 621 deaths from accidental burns (522) and 4020 deaths from accidental falls (3327) The number of suicides was 3822, compared with 3512 in the first nine months of 1953 The total number of deaths from respiratory tuberculosis in the whole of 1954 was 7069 compared with 7013 in 1953 Since 1947 the respiratory tuberculosis death rate has fallen by more than 65% The provisional cancer death rate in 1954 was 2222 per million population for men and 1862 per million for women The corresponding figures in 1953 were 2165 and 1835 respectively The rise in the rate for men includes an increase from 607 to 657 per million in deaths assigned to cancer of the lung and bronchus, making a total increase of 70% since 1947

* Not including late returns

Scotland in 1954

In a preliminary return for 1954 the Registrar-General for Scotland[1] reports that the birth rate continues the rise which began last year At 18·0 per 1000 population the birth rate was 0 2 more than in 1953 The infant-mortality rate was 31 per 1000 live births—the same as last year when the rate reached a new low record The death rate of 12 per 1000 population was 0 5 above the 1953 figure, but 0 3 below the average for 1949–53 The tuberculosis death rates are the lowest ever recorded.

Medicine and the Law

Negligence Action Settled

A Yorkshire miner has been awarded £350 agreed damages in respect of paralysis of the ulnar nerve following an injection in the left arm[2]

The plaintiff aged 50 was admitted to the Castleford Normanton and District Hospital in November 1951 for an operation for perforated peptic ulcer He was put to bed about 8 30 A.M and a male nurse gave him an injection of Omnopon and scopolamine At about 9 A.M. he was taken to an operating theatre and given an injection of thiopentone by the anæsthetist The injection caused him pain and he became unconscious. The operation was performed by a house-surgeon. During the operation it was alleged the surgeon and the anæsthetist were responsible for the care of the patient The plaintiff recovered consciousness at about 5 P.M that day and saw that his left arm, which was painful was tightly bandaged The next day the bandage was removed and he saw that his arm was black and swollen It remained in that condition until he was discharged.

The plaintiff sued the hospital management committee the surgeon the anæsthetist and the male nurse It was alleged that in injecting the thiopentone intravenously the anæsthetist had allowed the drug to penetrate into the surrounding tissues of the arm; that the bandage was applied too tightly that the defendants failed to observe the swelling of the arm and to slacken the bandage at the first opportunity; and that the arm during the operation was allowed to lie in such a position on the table as to cause the paralysis.

Evidence was given by a general practitioner whose patient the plaintiff had been for a number of years that there was nothing wrong with the patient's arm and that he had never had any trouble with it

During the trial a settlement was reached, damages being awarded against the management committee and the anæsthetist and the plaintiff withdrawing the allegations against the surgeon and the male nurse

Parliament

Health and Welfare of Non-industrial Workers

IN the House of Commons on April 1, Mr HAROLD DAVIES moved the second reading of a private member's Bill to implement the recommendations of the Gowers' Committee on conditions of work among non-industrial workers Since the report of this committee was published at the beginning of 1949, the Government had made promise after promise, and now they had the opportunity to act 12 million people working in agriculture, on the railways, in shops and offices, cinemas and theatres, in the catering trades, and as dental mechanics were unprotected by statutory minimum standards The Bill laid down standards for their health, welfare, and safety

Mr HEATHCOAT AMORY, Minister of Agriculture, agreed that the absence of a statutory code for non-industrial employment was an unjustifiable gap in our protective legislation Since the Gowers Committee reported, however, the Government departments concerned had translated many of their recommendations into concrete proposals which had been circulated to interested organisations as a basis for discussion and future legislation A vast amount of comment on these proposals had been given detailed consideration The Government were in entire agreement with the general object of the Bill, but in their opinion this subject was much too wide and complex to be dealt with properly by a private member's bill Any legislation which was introduced not only must be fair to all parties, but must be capable of effective enforcement Time could not be found in the remainder of the present session to do justice to such an important measure But the Government had already made it clear that it was their intention to introduce legislation of broadly the same scope as soon as parliamentary time could be found

QUESTION TIME

Recruitment of Dentists

Replying to a question, Mr IAIN MACLEOD, the Minister of Health, announced the eleven members of the Interdepartmental Committee, which he has set up, with the Secretary of State for Scotland, to ascertain the reasons for the lack of candidates for training as dentists Sir Arnold McNair, Q C, is to be the chairman and the medical and dental members are Mr J E H Duckworth, Sir Wilfred Fish, Prof A P Thomson, Mr J L Trainer, Mr R O Walker, and Prof F C Wilkinson.

Training of Nurses

Replying to a question, Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Ministry of Health, said that the Minister was inviting representatives of the London teaching hospitals to discuss the further secondment of student nurses with his officers next month At Dec 31, 1953, the ratio of beds to nursing staff was 1 27 to 1 in the London teaching hospitals, and 1 79 to 1 in general hospitals under the Metropolitan regional hospital boards

Hospital Pharmacists

Replying to questions, Mr MACLEOD said that he was aware of the shortage of pharmacists in the hospital service In August last there were deficiencies on complements of 281 in the basic grade and 64 in the senior grade There was no nationally agreed salary for hospital pharmacists Payment varied according to the prevailing rate in the area In the Metropolitan area the standard salary of a hospital pharmacist in the basic grade was £450 a year at age 23, rising by annual increments of £25 to £575 with an extra £20 or £30, according to age A claim for salary increases was before the Pharmaceutical Whitley Council It was true that in many cases locums were not as well qualified as the men under whom they must serve, but that by and large they got substantially more than the permanent officers The question whether there should be national rates for locums was a matter that he was sure that the two sides of the Whitley Council would discuss in the negotiations

Group-practice Loans

to a question, Miss HORNSBY-SMITH said that at larch, 1955, in England and Wales, some £36,000 had been paid to eleven partnerships, including 38 as loans for the establishment of group practice

Needs of Elderly Patients in Edinburgh

Mr E G WILLIS asked the Secretary of State for Sco if he was aware that in a recent survey in Edinburgh, 159 doctors of 5086 elderly patients, it was discovered there was a large need for physiotherapy, that some had need of domestic medical assistance and 1270 we need of nursing, hospital treatment or rehabilitation.—C mander T D GALBRAITH replied This survey was cond as part of a joint study, in which Edinburgh Corporation the South Eastern Regional Hospital Board are particip of the needs of elderly patients in Edinburgh The assess of its findings, in particular as to the relative importanc the various needs reported by the general practitioners, matter primarily for these authorities, who will I am take careful note of them in considering the developmen the various services for which they are responsible u statute

Mr WILLIAM ROSS asked the Minister whether, in c quence of the findings of the survey, he would institu national survey into the condition and needs of Scotl chronic sick and old people —Commander GALBRAITH repl Arrangements of varying kinds have been made in diff parts of the country for the joint study by local author hospital boards, and executive councils of the needs to be by their services catering for old people and the chronic But the survey procedure adopted in Edinburgh has not employed elsewhere, and its findings have still to be eval by the bodies concerned

Priority Dental Treatment in Scotland

Replying to a question, Mr JAMES STUART, Secreta State for Scotland, said that in the 12 months to June, it was estimated that expectant and nursing mothers, chil and those under 21 years of age received 198,000 cours dental treatment, or 17% of the total provided unde general dental service In the 12 months to December, the number of such courses was about 650,000, or 57% c total.

Radioactive Content of London Atmosphere

Dr BARNETT STROSS asked the parliamentary secreta the Ministry of Works, as representing the Lord Preside the Council, when measurements were first commence London on the radioactive content of the atmosphere how long such measurements had been taken by the ph department of the Marsden Hospital, and how the techn used there compared with or varied from that used by Medical Research Council —Mr J R BEVINS replied measurements of atmospheric radioactivity in London e than 1947 are known Since that date measuremen radiation backgrounds have been made in the physics de ment of the Royal Marsden Hospital, these are the mea ments made under the auspices of the Medical Res Council Other measurements made in the physics depart since 1930 were designed to ascertain the degree of expos workers using X ray apparatus and radium

Spastic Paralysis and Cerebral Palsy

Replying to questions, Mr JAMES STUART, Secreta State for Scotland, said that compulsory notification hitherto been confined to infectious conditions, and he not think there was enough to be gained to justify a pro to depart from that principle for spastic patients. Me officers of health in Scotland had been asked to includ their annual reports for 1954, statements of inform available about the incidence of spastic paralysis or cer palsy in each area, and to review the facilities available u the local health services for people with this handicap T had also been asked to review the degree to which t facilities were being coördinated with the diagnostic treatment services and with the welfare services When information had been received, he proposed to consider position further

Fluoride Content of Water-supplies

Replying to a question, Mr DUNCAN SANDYS, Ministe Housing and Local Government, said that the officials of Ministry were collecting information about the fluo content of the water supplied by statutory water undertal in England and Wales, beginning with those serving population of more than 100,000

In England Now

Running Commentary by Peripatetic Correspondents

THE newspaper strike, to most a passing inconvenience, has shattered the pattern of my life. It happened like this. For nearly ten years now I've belonged to the best of all clubs—a carriageful of commuters on the 8.8 to Town. There was the bowler-hatted *Times* whom I judged to be a senior Civil Servant; three *Daily Telegraphs*; a fellow who clearly didn't know his own mind, since in the autumn of 1948 he switched from the *Mail* to the *Express*; and a parvenu left-wing newcomer with us only since 1949, who despite our silent disapprobation stuck to the *Herald*. Yet even him we eventually absorbed into the group.

The strike came; and we faced each other, unshielded, for the first time. For several mornings the *Times* opposite me gazed resolutely at Sunny Ilfracombe above my head; and I read above his, How to Get Free Insurance Every Sixth Year. We couldn't go on like that: the mounting tension had to be released. Yesterday morning a stranger got in with the *Manchester Guardian* under his arm, and with oafish mindlessness to the prevailing sense of strain sat down and began to read it. We looked at each other: unanimity was complete. As we handed round the divided sheets a little ripple of talk sprang up and the ripple grew to a torrent. The *Times*, I learnt, was a successful bookmaker who liked to keep himself up with world affairs; while the *Herald* was a Conservative Party official who believed in knowing the enemy. But this bout of chattering was inevitably followed by reaction. As the train drew into the terminus the thaw ended, and we parted with uncertain gestures of farewell, leaving the *Guardian* to gather his scattered pages.

Farewell indeed it was. This morning I got into our accustomed carriage. Only the *Herald* was there, and he hastily hid his face behind the *Spectator*. The others were risking no repetition of yesterday's debauch. I shall miss our silent club. But thank heaven we British have our *standards*—which brook no garrulousness on the 8.8 to Town.

* * *

Whether to tell the doctor is a *complex problem*, but an accepted ethical hazard of being a patient. For instance, *when ill with a high* temperature, pains in the back and limbs, and a headache, you may suggest that you have flu, though there is always the risk that your doctor will bitingly reply that it is his job to make the diagnosis. On the other hand merely to enumerate your symptoms may attract a diagnosis of "*mild pyrexia* with hysterical overlay." The solution is to *know* your doctor and treat him as a whole person with a definite personality and background. *If you are suffering from* vague aches and pains, *not clearly fitting* any described disease, then your problem is more difficult. If you are certain you have a completely new disease, then the more details you can describe the better. Of course your illness will be called after the doctor, unless your name is Easter, Whitsun, or August, and the publication of your illness occurs at the topical bank holiday; but that is really a small loss for having a real illness. If you are not so lucky as to have a new disease, then beware! Study your doctor and decide whether you need medicine or sympathy. If the former, then stress the dominant pain and keep quiet about the others; if the latter throw out some hints about pressure of work, hard-hearted parents, bureaucracy, and Civil Servants (always a winner). Don't tell him straight away that it's your nerves, but let him tell you, and don't, whatever you do, follow up his diagnosis by asking "which nerve?"; remember only the doctor may make such jokes; for the patient to do so shows a blunting of affect and shallowness of emotion. The doctor will reassure you that though he agrees that your pain is really there, it isn't really. You may well leave him muttering:

As I was going up the stair
I had a pain that wasn't there;
It wasn't there again today;
I wish my pain would go away.

* * *

I was listening the other day to the long, sad story of an unwanted child, and of her ill treatment by her parents, the world in general, and her fellow patients—which had precipitated the present crisis—when my somnolence and dutiful yes, yeses were rudely shattered. Striking her most dramatic pose she sobbed: "Oh! I wish I were dead! Oh! Doctor! Give me Oblivion."

Covering my confusion with a gentle "now! now!," I thought of warning Sister, calling psychiatric aid, and delivering a little homily dissociating myself from the recently expressed view of certain management committeemen. But I was saved further mental exertion when she remarked: "A friend of mine recommended it and said she had found it wonderful." I hurriedly agreed and joined her in a quick drachmstat.

* * *

Our small Canadian hospital is trying to organise itself to meet the requirements of the Joint Commission on Accreditation of Hospitals, an august body with headquarters in Chicago. The medical staff is enforcing the following formalities on itself.

Patients' histories must be written within 48 hours of admission, before any *operation is performed*, and on a standard form with a terrifying check list of all imaginable signs, symptoms, and possible previous illnesses. These are checked by the *records committee* which is composed of three members of the medical staff.

A *tissues committee* checks the operation done by the surgeon with the preoperative diagnosis and the pathologist's report on the operation specimen. The question was raised at one staff meeting as to who checked *the pathologist*, but after a slight pause this blasphemy was skated over.

A Gallup poll has apparently established norms of permitted *medical naughtiness*. For instance, you are permitted to remove up to 15% of tissue later reported normal pathologically; to have up to 1% of patients die in the first ten postoperative days; to have a maternal death rate of up to 0·25% and a neonatal death rate of up to 2%. But anything over the norm is held to be *distinctly fishy and in need of* investigation.

A *credentials committee* assesses the qualifications of staff members and suggests promotion or demotion.

As our staff, like the hospital, is small, almost every doctor is on at least one committee. *Consequently* Dr X on the tissues committee cannot be too uppity with Dr Y (whose appendix was reported by the pathologist to be normal, though in the middle of the night before operation it appeared clinically so acute) because Dr X knows full well that Dr Y is on the records committee and Dr X has been rather slack with his histories. Justice therefore tends to be tempered with mercy. I think we shall manage all right; being doctors we know only too well the fallibility of medicine as a science.

* * *

He was a curious character—long haired, pedantic of speech, and in his middle thirties. Once an antique dealer, he was now odd-job *man in a doss* house. He had had attacks of acute pulmonary œdema and he had murmurs in his heart about which the experts found it hard to *agree*, *so that* he was a *difficult* case to teach upon. However, he seemed to enjoy the class and corrected his student's history several times. As we left his bed after much discussion he said: "Excuse me Sir, but if I may make one further observation, I suggest that my murmurs are neither systolic nor diastolic, but apostolic."

* * *

I see as I go round the town
How one goes up and one goes down;
How brother clasps the hand of brother
And how they knife at one another.

A beech tree standing in a glade
Smothers its offspring with its shade;
The little beeches scarce will thrive
While the ancient beech remains alive.

Day by day and hour by hour
Strength vies with strength and power with power
To urge on us and every nation
A thermonuclear termination.

This isn't the whole of the truth about man,
So think up the rest of it if you can.

Letters to the Editor

PREPARATION FOR WAR

SIR,—Though hardly anybody anywhere wants a third world war, we see a continuing increase in preparations for war, with a progressive accumulation of power to destroy life The preparations made by each opposing group are regarded by the other as a threat to life and liberty, but governments are not averse from engendering fear, because they believe it will deter their opponents from aggression The world's governments are acting, in fact, as though they believed that the increase of fear is in the interest of peace It is, of course, just possible that this belief will be eventually justified—that, when all countries have enough reason to be frightened of war they will prefer some lesser risk On the other hand it is quite certain that the immediate effect of fear is to induce nations to amass more arms With very few exceptions, students of human motivation believe that fear facilitates the outbreak of war, and that peace is more likely to be gained by diminishing fear than by increasing it

From childhood onwards we all go through a series of crises in which a choice has to be made between (1) facing and accepting facts, however unwelcome, and (2) trying to dominate the situation for our own purposes In biological terms, our problem is to know how far we can adapt our environment to ourselves, and how far we must adapt ourselves to our environment Complete subjugation of the world to one's wishes is possible only in fantasy the attempt to enforce it in reality, by sheer force of will or by loudness or plaintiveness of demand, is effective only in the special circumstances of the child At the same time, complete submission of the self to the demands of others is neither necessary nor desirable Success is attained mainly by adapting ourselves to the needs of others and so influencing them to help us

From childhood onwards we learn the great truth that people, like things, have to be understood before they can be controlled Any attempt to convert an enemy into a friend needs courage there must always be some risk that he will attack as soon as one has lowered one's defences But the major difficulties are not our justifiable fears so much as our self-deceptions, which trap us into trying to triumph completely, as in a world of infantile omnipotence, rather than to achieve mutual understanding and constructive mutual surrender in the world of reality

It is convenient, for mental comfort, to believe that those who conform to one's wishes are good, while those who seem to frustrate them are bad Moreover, if men can make themselves believe—as they can and do—that the majority of the good people are on their own side of the curtain, while the majority of bad people are on the other, conflict is more effectively externalised On both sides people need someone on whom to project their own antisocial wish to dominate their neighbours, of which they themselves disapprove, and thus each side performs for the other the comforting service of scapegoat But the price of such self deception is incalculable What can we really expect from the mutual fanning of suspicion, fear, and hatred?

London W 1 J NORMAN GLAISTER

GENETIC EFFECTS OF THERMONUCLEAR EXPLOSIONS

SIR,—I wish it were possible to share Dr Carter's optimism, in his letter last week, about the possible genetic effects of experimental thermonuclear explosions in peace time, but his expectations regarding "the eugenic counter measures which mankind will surely take" are nothing more than wishful thinking of the most type It is regrettably plain to anyone with much experience of human affairs that in c even uneasy peace eugenic strivings will be defe religious or conscientious scruples, by basic urges, and even by a sort of sheer cussedness which defy the advice of the Eugenics Society precisely it is the advice of such an organisation! If world nuclear war should break out perhaps these sc be overcome or over ruled, but it is doubtful w organised government will persist in such a form a be able to apply eugenic principles in time The one can hope is that a few people, at the end of time, will have started practical fumblings toward Dr Carter would like to see

With the more optimistic among the scientists l that the tolerance of human genes to radiation is times greater than the present level of backgro radiation, but it is possible that in fact humanity achieved only a marginal adjustment and that anyth over, say, a doubling of the present sea level amo might be dangerous We do not know and cannot until a good deal more research has been carried out

Two things, however, are known that genetic dam is irreversible and that a considerable part of the r active material liberated by these explosions remains, all intents and purposes, permanently active It fol that by the time human observation shows that danger point has been reached the damage will have b done and nothing will undo it Common prudence w suggest, therefore, that experimental explosions sho cease until such time as investigations have provide little more information as to what level of radiation be regarded as safe In spite of the difficulties involved in extrapolation, two or three years of intelligently pla laboratory experiment ought to give some inte approximate result and might indicate a permis rate at which the physicists might continue to let off the fireworks

Some highly reputable physicists have already sa that the next stages in the development of nucl weapons can be carried on without test explosion Politically, therefore, a suspension of explosions wh intensive genetic research goes on is feasible and sa Medically and eugenically it is hard to see why a doctor should hesitate to press for such a suspension.

Public Health Department,
Colchester JOHN D KERSHAW

SIR,—Why does Dr Carter consider desirable th maintenance of the human species in its normal, estab lished genetic pattern? To what end does he hop mankind "is prepared to undertake control of his ow evolution," or to what purpose does he think mankin "will surely take" eugenic counter measures again "irreversible genetic deterioration"? What civil does he see ahead?

As a second question, may I ask him whether th "methods of achieving highly selective reproduction" would be applied as a dictate of intelligent (and free planning, or as the inevitable (and not freely chosen result of mankind's instinct for self preservation? the former, again may I ask what is the aim of the plan If the latter, I wonder if this instinct itself is genetically typed and likely to be influenced by mutations

Holt Norfolk J N COZENS HARDY

THE DOCTOR, HIS PATIENT, AND THE ILLNESS

SIR,—I read with great interest Dr Balint's article of April 2 Most of us have met the patient who needs a "bad" doctor, but I, as a consultant, only met him once

It was one of my earliest consultations An elderly man came to me complaining of hairy black tongue I had seen the condition in dogs, but though I knew it occurred in man, I had never met it I inquired about diet and I found that he ed largely on bread and meat and was therefore flatulent l constipated.

He handed me two sheets of foolscap on which were cata ued the opinions and advice of 17 leading skin specialists England, France, and Germany and with great joy he d me they were no use at all Though not a leading specialist was considered worthy to contribute my scalp

I advised him to eat more vegetables and fruit and to have raviolet light (new in those days when there were no amin B preparations) His black tongue vanished at once d he never forgave me His cherished symptom and his t of bad doctors were his *raison d être* and reverting to his i ways, he did not live very long for which he was thankful believe.

CLINICAL STAGING OF CARCINOMA OF THE BREAST

SIR,—I should like to be allowed to add a footnote Mr Michael Harmer's letter of March 26

There is associated with this department which is sponsible for statistical analysis of data relating to ses of cancer registered in England and Wales, a ommittee under the chairmanship of Dr A H T obb-Smith which advises on cancer statistics generally d on the national registration scheme in particular t recent meetings this committee, which is a sub ommittee of the Registrar General s Medical Advisory ommittee (chairman, Sir Ernest Rock Carling), has en much concerned with the problem of establishing niform systems of staging Largely for the reasons numerated by Mr Harmer it has selected the breast s the most suitable site for immediate study In doing is, the committee is of course taking account of arious existing methods of staging including those onsidered at the sixth congress of the International nion against Cancer

General Register Office
London, W.C 2. R M BLAIKLEY

BURNS FROM ELECTRIC BLANKET

SIR,—Dr Neville Davis (April 2) writes about a child ho received a shock from an electric blanket which had ecome wet with urine The danger is from using electric lankets heated directly from the mains By far the afest plan is to have a blanket taking its current at a oltage not greater than, say, 20 from the output side a mains transformer Suitable transformers can be ought new made up to specification, or obtained second and. The transformer should have an output of about 00 watts the secondary side should be tapped to give 0 volts and 6 volts. The cost of a new transformer is bout £4 and a second hand one about 35s

An electric blanket measuring 4 ft 6 in. × 5 ft. (suitable for double bed) can be made up from two bed sheets or any imilar material between which is threaded 45 yards of plastic overed bell wire (outside diameter 1 mm) obtainable from Woolworths at 1½*d* per yard The wire is threaded back ards and forwards across the sheets and the sheets machined etween each turn and around the edges; the two ends of the wire are brought out of one corner

The transformer should be mounted in a good strong box he mains side wired in three-core rubber cable and properly arthed. The secondary side should be switched to give the utput either from 20 volts (high) or 6 volts (low); this side may be earthed to the frame of the transformer The transformer box is placed near the head end of the bed and the blanket plugged into a 2 amp. socket with a two pin plug

On a bitter cold night the bed will be warmed up to luxury omfort in about twenty minutes when switched on high If then switched to low and left it will be very pleasant ll night On a less cold night it can be switched off altogether when about to go to sleep

The blanket is absolutely safe There is no danger from shock through passing urine in the bed or spilling water when washing or bathing an invalid The blanket can be made at home for about £1 The transformer can be mounted in a box and wired also at home if father is a competent craftsman, or it can be done outside for about £5 The total cost is about £6 as against about £12 charged for mains voltage electric blankets We have had one in our house throughout this past winter; the comfort of it is wonderful

Twickenham Middlesex. J MADDISON

SURGERY IN HÆMOPHILIA

SIR,—Dr Walker's most interesting and full report (April 9) of gastrectomy in a hæmophiliac undoubtedly succeeds in its main object—that of underlining the extreme risk of surgery in hæmophilia however mild Even minor operations should be avoided in these patients whenever possible, and only carried out under cover of transfusion and with full laboratory control Major surgery should be resorted to only if it provides the one hope for the patient s survival.

Exchange transfusion as carried out in Dr Walker's patient, affords the best preoperative preparation at present generally available In view of the admitted instability of antihæmophilic globulin in vivo as well as in vitro however operation should be performed as soon as the exchange is completed. It is probable that Dr Walker's patient would have required less blood and plasma postoperatively had the gastrectomy been performed immediately after the exchange transfusion instead of twenty hours later

St. Thomas's Hospital
London S.E 1 R M HARDISTY

THE ACTION OF CHLORPROMAZINE

SIR—I am glad that Professor Samson Wright (April 2) is prepared to suspend judgment on the unconventional explanations offered by French authorities In fairness to them I feel I must point out that it is difficult to set out in a brief review the results of twenty years research by a team of full time workers and it is possible I have not done full justice either to their experimental methods or their explanation of their findings. Furthermore the fact that their work is little known in Anglo-Saxon countries is explained in part by their isolation during the German occupation of France and in part by their reluctance to publish their failures to achieve a satisfactory method of preventing the development of their syndrome

In 1935 O Shaughnessy and Slome[1] came to rather similar conclusions after their work which showed the effectiveness of spinal anæsthesia in preventing the development of traumatic shock in cats After noting the ineffectiveness of attempts to compensate for fluid loss by intravenous therapy they stated

> "Up to the present, apart from perfunctory administration of morphia too little attention has been paid to the nervous side The body possesses ample reserves of fluid and the shocked case who recovers does so because he has been able to replenish a diminished volume by drawing on natural resources. We have suggestive evidence that it is the continuance of abnormal impulses which prevents this natural reaction on the part of the organism and if these impulses can be controlled this favourable reaction takes place Some better method of controlling nociceptive impulses may be devised—but control in some form is essential for the successful treatment of this syndrome.

Over 50 years ago George Crile reached rather similar conclusions on which he based his anoci association and kinetic theories of shock. Present-day opinion seems to agree about the specificity of the reactions of the organism to non specific aggression or 'stress, although attention in this country and America seems to have been directed towards endocrine activity to supply the explanation In spite of this little significant progress has been made with endocrine extracts in the prevention of the evolution of these syndromes

SIR,—I wish it were possible to share Dr Carter's optimism, in his letter last week, about the possible genetic effects of experimental thermonuclear explosions in peace time, but his expectations regarding "the eugenic counter measures which mankind will surely " are nothing more than wishful thinking of the most alistic type It is regrettably plain to anyone with much experience of human affairs that in cond even uneasy peace eugenic strivings will be def religious or conscientious scruples, by basic urges, and even by a sort of sheer cussedness w defy the advice of the Eugenics Society precisely it is the advice of such an organisation ! If w nuclear war should break out perhaps these scru be overcome or over-ruled, but it is doubtful organised government will persist in such a fo be able to apply eugenic principles in time T one can hope is that a few people, at the end time, will have started practical fumblings tow Dr Carter would like to see

With the more optimistic among the scientist that the tolerance of human genes to radiation times greater than the present level of bac radiation, but it is possible that in fact huma achieved only a marginal adjustment and that over, say, a doubling of the present sea level might be dangerous We do not know and cann until a good deal more research has been carried

Two things, however, are known that genetic is irreversible and that a considerable part of th active material liberated by these explosions rem all intents and purposes, permanently active I that by the time human observation shows danger point has been reached the damage will h done and nothing will undo it Common pruden suggest, therefore, that experimental explosion cease until such time as investigations have pr little more information as to what level of radia be regarded as safe In spite of the difficulties inv extrapolation, two or three years of intelligently laboratory experiment ought to give some approximate result and might indicate a pe rate at which the physicists might continue to let fireworks

Some highly reputable physicists have alrea that the next stages in the development of weapons can be carried on without test ex Politically, therefore, a suspension of explosio intensive genetic research goes on is feasible a Medically and eugenically it is hard to see w doctor should hesitate to press for such a suspe

Public Health Department,
Colchester JOHN D KERS

SIR,—Why does Dr Carter consider desira maintenance of the human species in its normal lished genetic pattern ? To what end does mankind "is prepared to undertake control of evolution," or to what purpose does he think "will surely take" eugenic counter measures "irreversible genetic deterioration" ? What does he see ahead ?

As a second question, may I ask him whet "methods of achieving highly selective reprod would be applied as a dictate of intelligent (a planning, or as the inevitable (and not freely result of mankind's instinct for self preservatio the former, again may I ask what is the aim of th If the latter, I wonder if this instinct itself is gen typed and likely to be influenced by mutations

Holt, Norfolk J N COZENS HA

THE DOCTOR, HIS PATIENT, AND T ILLNESS

SIR,—I read with great interest Dr Balint's of April 2 Most of us have met the patient wh a "bad" doctor, but I, as a consultant, only m once

It was one of my earliest consultations An elde came to me complaining of hairy black tongue I h the condition in dogs, but though I knew it occurred I had never met it I inquired about diet and I found ved largely on bread and meat and was therefore flatulent nd constipated.

He handed me two sheets of foolscap on which were catalogued the opinions and advice of 17 leading skin specialists n England France, and Germany and with great joy he old me they were no use at all Though not a leading specialist was considered worthy to contribute my scalp

I advised him to eat more vegetables and fruit and to have ultraviolet light (new in those days when there were no vitamin B preparations) His black tongue vanished at once, and he never forgave me His cherished symptom and his list of bad doctors were his *raison d'être* and reverting to his old ways, he did not live very long for which he was thankful, I believe.

Bitton, near Bristol. A. T TODD

CLINICAL STAGING OF CARCINOMA OF THE BREAST

SIR,—I should like to be allowed to add a footnote to Mr Michael Harmer's letter of March 26

There is associated with this department which is responsible for statistical analysis of data relating to cases of cancer registered in England and Wales, a committee under the chairmanship of Dr A H T Robb-Smith which advises on cancer statistics generally and on the national registration scheme in particular At recent meetings this committee which is a subcommittee of the Registrar General's Medical Advisory Committee (chairman Sir Ernest Rock Carling), has been much concerned with the problem of establishing uniform systems of staging Largely for the reasons enumerated by Mr Harmer it has selected the breast as the most suitable site for immediate study In doing this the committee is of course taking account of various existing methods of staging including those considered at the sixth congress of the International Union against Cancer

General Register Office
London, W C.2

R M BLAIKLEY

BURNS FROM ELECTRIC BLANKET

SIR—Dr Neville Davis (April 2) writes about a child ho received a shock from an electric blanket which had ecome wet with urine The danger is from using electric lankets heated directly from the mains. By far the fest plan is to have a blanket taking its current at a ltage not greater than, say 20 from the output side mains transformer Suitable transformers can be ght new, made up to specification, or obtained second and The transformer should have an output of about 00 watts the secondary side should be tapped to give 0 volts and 6 volts The cost of a new transformer is bout £4 and a second hand one about 35s

An electric blanket measuring 4 ft 6 in × 5 ft (suitable for double bed) can be made up from two bed sheets or any imilar material between which is threaded 45 yards of plastic overed bell wire (outside diameter 1 mm.) obtainable from Voolworths at $1^1/_2d$ per yard The wire is threaded backwards and forwards across the sheets and the sheets machined etween each turn and around the edges; the two ends of he wire are brought out of one corner

The transformer should be mounted in a good strong box the mains side wired in three-core rubber cable and properly earthed The secondary side should be switched to give the output either from 20 volts (high) or 6 volts (low) this side may be earthed to the frame of the transformer The transformer box is placed near the head end of the bed and the blanket plugged into a 2 amp. socket with a two pin plug

On a bitter cold night the bed will be warmed up to luxury comfort in about twenty minutes when switched on high If then switched to low and left it will be very pleasant all night On a less cold night it can be switched off altogether when about to go to sleep

The blanket is absolutely safe There is no danger from shock through passing urine in the bed or spilling water when washing or bathing an invalid The blanket can be made at home for about £1 The transformer can be mounted in a box and wired also at home if father is a competent craftsman, or it can be done outside for about £5 The total cost is about £6 as against about £12 charged for mains voltage electric blankets We have had one in our house throughout this past winter the comfort of it is wonderful

Twickenham Middlesex. J MADDISON

SURGERY IN HÆMOPHILIA

SIR,—Dr Walker's most interesting and full report (April 9) of gastrectomy in a hæmophiliac undoubtedly succeeds in its main object—that of underlining the extreme risk of surgery in hæmophilia, however mild Even minor operations should be avoided in these patients whenever possible, and only carried out under cover of transfusion and with full laboratory control Major surgery should be resorted to only if it provides the one hope for the patient's survival

Exchange transfusion, as carried out in Dr Walker's patient affords the best preoperative preparation at present generally available. In view of the admitted instability of antihæmophilic globulin in vivo as well as in vitro however, operation should be performed as soon as the exchange is completed. It is probable that Dr Walker's patient would have required less blood and plasma postoperatively had the gastrectomy been performed immediately after the exchange transfusion instead of twenty hours later

London S.E 1

R M HARDISTY

THE ACTION OF CHLORPROMAZINE

SIR,—I am glad that Professor Samson Wright (April 2) is prepared to suspend judgment on the unconventional explanations offered by French authorities In fairness to them I feel I must point out that it is difficult to set out in a brief review the results of twenty years research by a team of full time workers and it is possible I have not done full justice either to their experimental methods or their explanation of their findings. Furthermore, the fact that their work is little known in Anglo Saxon countries is explained in part by their isolation during the German occupation of France, and in part by their reluctance to publish their failures to achieve a satisfactory method of preventing the development, of their syndrome.

In 1935 O Shaughnessy and Slome [1] came to rather similar conclusions after their work which showed the effectiveness of spinal anæsthesia in preventing the development of traumatic shock in cats After noting the ineffectiveness of attempts to compensate for fluid loss by intravenous therapy they stated

> "Up to the present apart from perfunctory administration of morphia, too little attention has been paid to the nervous side The body possesses ample reserves of fluid and the shocked case who recovers does so because he has been able to replenish a diminished volume by drawing on natural resources. We have suggestive evidence that it is the continuance of abnormal impulses which prevents this natural reaction on the part of the organism and if these impulses can be controlled this favourable reaction takes place. Some better method of controlling nociceptive impulses may be devised—but control in some form is essential for the successful treatment of this syndrome.

Over 50 years ago George Crile reached rather similar conclusions on which he based his anoci association and kinetic theories of shock. Present-day opinion seems to agree about the specificity of the reactions of the organism to non specific aggression or "stress," although attention in this country and America seems to have been directed towards endocrine activity to supply the explanation In spite of this little significant progress has been made with endocrine extracts in the prevention of the evolution of these syndromes

---

[1] O'Shaughnessy L., Slome D *Brit J Surg* 1935 22, 617

It would appear, therefore, that neurogenic theories deserve re consideration, and it is hoped that Professor Samson Wright's restrained and open-minded attitude will encourage further study of French ideas in this country and America

London S E 11

D A BUXTON HOPKIN

IRON-DEXTRAN COMPLEX IN MICE AND MEN

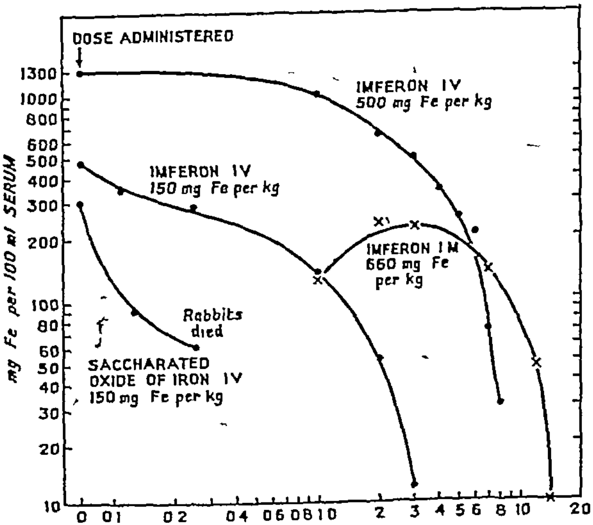
SIR,—We feel that certain comments are called for by the interesting observations reported by Dr Nissim in your issue of April 2 The administration of the iron-dextran complex 'Imferon' to mice in doses which provided 500 mg of metallic iron per kg of body-weight, *with survival of the animals*, was only possible because of the exceptionally low acute and chronic toxicity of this complex Such large doses permit a degree of experimental siderosis never hitherto achieved They are therefore of interest in relation to hæmochromatosis, post transfusion hæmosiderosis, and nutritional cytosiderosis

It should be emphasised, however, that doses of this magnitude bear no relation to even the greatest degree of therapeutic excess The usual *total* dose in man is 20 mg per kg, and in any event is unlikely to exceed 50 mg per kg As Dr Nissim has pointed out[1] in connection with intravenous saccharated iron oxide

> "The doses required for the production of lesions in the rat and mouse are not less than 1 0 g Fe/kg given over a period of 3 months This corresponds to 60 g Fe for a 60 kg adult, and would require some 50 courses of treatment in a case wrongly diagnosed as iron deficiency anæmia"

In Dr Nissim's experiments with imferon the maximum dose was increased up to 3 g Fe per kg over a period of six weeks or less—in animals which were neither anæmic nor depleted of their body-iron reserves

In the ordinary course of pharmacological testing of imferon its acute and chronic toxicity were studied Within the limits of dosage applicable to man, with a wide margin of safety, no depression of spermatogenesis was observed in mice and rabbits Single doses in mice ranged from 100 to 1375 mg Fe per kg intravenously The animals were killed six days later and the iron deposition in the testes was found to vary from a few granules in occasional interstitial cells (at the lower dose) to heavy infiltration associated with fluid staining blue by Perles's method (higher doses) In the rabbit a dose of 650 mg Fe per kg intramuscularly revealed



only a scanty retention of iron in the int
of the testes six weeks later In no insta
evidence that spermatogenesis was in any
The statement that the deposition of iron
following imferon is "more massive than
organ in the body" presumably refers to
iron after eleven weeks, since the initial
is of course heaviest in liver and spleen

The significance of the difference betweer
and saccharated oxide of iron becomes evid

DANGER OF VITAMIN-K ANALOGUES TO NEWBORN

SIR,—In connection with Dr Allison's disquieting observations on the hæmolytic effect of 'Synkavit' in premature infants (March 20), we have carried out studies, during the past year, on the effect of water soluble vitamin K substitutes on rats On the suggestion of Dr Allison intramuscular injections of synkavit were made, at the level of 10 mg per 100 g body weight into rats deprived for long periods of vitamin E Within a few hours most of the animals became listless or appeared uncomfortable, and an intense hæmoglobinuria ensued Except in a few cases the immediate injury was temporary and both the animals and their urine appeared normal on the following day

Hæmoglobinuria was never observed after injections of synkavit into normally nourished rats or into rats given a basal diet deficient in vitamin E but with adequate supplements of tocopherol When administered orally, synkavit appeared to be harmless even to rats deficient in vitamin E Injections of an aqueous preparation of vitamin K_1 were also harmless to such animals. Preliminary trials with vitamin K substitutes other than synkavit have indicated wide variations in their degree of toxicity, some appearing completely innocuous but others much more toxic than synkavit on a weight-for weight basis

Dunn Nutritional Laboratory,
University of Cambridge and
Medical Research Council
T MOORE
I M SHARMAN

SIR,—Dr Allison's views on the possible dangers of he administration of vitamin K analogues to premature nfants are of great interest. Recent experience in the Derby premature baby unit may perhaps lend clinical upport to these views

The routine care of all babies in this unit was modified recently and the dose of water-soluble vitamin K ynkavit) was increased from 10 mg once on admis on to 10 mg t.d.s. for three days. To my dismay hortly after the introduction of this routine six babies eveloped clinical signs of kernicterus and subsequently ied between the ages of 6 and 13 days. Their birth eights ranged from 2 lb 6 oz to 4 lb 7 oz. Blood investi ations did not show any evidence of rhesus or other lood-group abnormality At necropsy Dr G R Osborn ound typical yellow staining of the basal ganglia

It seems possible that the increased dose of vitamin K ontributed to the kernicterus in these babies, though bviously the condition may have arisen quite fortui ously

This was a most unpleasant experience but I hope Sir, hat others may consider and comment on the implica ions of Dr Allison's findings and this clinical report

Derby
BERNARD LAURANCE

PROTECTING THE MOTORIST

SIR,—In your leading article of Feb 26 you refer to arious ways of increasing the motorist's safety

I gave up a convertible (drop head) coupé and bought sedan (saloon) to secure the strength of steel should the ar overturn Next I purchased a pair of safety belts for he front seat While the central belts are anchored to he floor on either side of the shaft the lateral belts are astened by plates and screws to the rear edges of the ront doors (our doors are hinged at the front) As a result he more the doors tend to open in a crash the more securely one is held in place The belts are of the airplane type and are easily opened

You suggest that such belts might be uncomfortable, but I am very happy with them. Because one is held securely there is not the fatigue of spinal flexors and extensors constantly contracting and relaxing to maintain posture Unlike the airplane seat (deep and enclosed'), the motor-car seat—at least in American cars—is not of the bucket variety, and there is thus no sense of cramping as in airplanes I agree that a harness would be better—one large company of car makers is said to be planning its manufacture

Both in Congress and in various State legislatures Bills have been introduced to make obligatory the installation of safety belts in new cars

RUPTURE OF LAPAROTOMY WOUNDS

SIR,—During the last eight years like Mr Mills (March 20), I have used continuous nylon sutures for the repair of abdominal wounds and hernias; but, while I agree that this reduces to a minimum the risk of rupture of the wounds or of development of hernias, it does have some disadvantages.

The main disadvantage is the risk of infection and sinus formation, and if the method is used routinely then I think this complication is likely to occur more frequently than Mr Mills suggests In my units I have been very satisfied with this method of suturing in the case of hernias, but when it was being used in the repair of laparotomy wounds the incidence of sinus formation and the need to remove the nylon made us decide that it was not suitable in every case

Once infection starts it carries on until all the nylon is removed It is useless to delay removing the nylon or to try the effect of antibiotics The wound has to be opened up the nylon removed in its entirety and the wound lightly packed with tulle gras or similar dressing To be content with removing only part of the nylon or partly resuturing the wound after removing it, inevitably results in failure to heal. One of the disappointing features is that wounds that have apparently healed perfectly by first intention sometimes break down months afterwards

While sinus formation is the main disadvantage there are two other minor complications. A few patients complain that their wound feels tight and they do not seem to be able to stretch presumably due to the inelasticity of the nylon suture and an even commoner complaint is that the knot forms a lump often tender under the skin

There is no doubt that sinus formation does represent a failure in asepsis, and I have come to the conclusion that it is not a suitable technique for standard use in a busy teaching hospital in the dirty atmosphere of a city with the theatre full of students and many of the operations being performed by registrars. But I have continued to use it routinely when working under nearly perfect conditions in an air-controlled theatre outside the town, with a minimum of persons in the theatre and only one abdominal operation being done at a time Under these conditions I have had only two cases of wound infection in the last eight years.

I have found that no 7 nylon is rather stiff to use, feels lumpy under the skin—especially in thin patients—and the knots are frequently prominent and painful I prefer a 44 inch length of no 5 black nylon doubled, and the ends knotted With the double length there is no question of the needle coming unthreaded as it so often does with a single length When the suture is completed one width of nylon is cut, the final stitch is inserted and then the two ends are tied. This makes for a smaller knot, and the first and last stitches can easily be inserted so as to make the ends turn in to the deeper tissues

Liverpool
J B OLDHAM

BEHÇET'S SYNDROME

SIR,—The paper by Dr Phillips and Dr Scott (Feb 19) has attracted a great deal of attention The article, however, illustrates one of the main dangers of eponymous description It is not true that Behçet's syndrome "has seldom been recorded in this country" Under a large variety of titles many papers have been written about it in England and America A fuller bibliography was given by me in a paper which I wrote over 14 years ago,[1] and since then there has been an extensive literature on the subject

I myself have seen over a hundred cases of associated recurrent vaginal and oral ulceration, and in almost all of these patients the ulceration occurred with a definite relationship to menstruation—hence the title of my article was Cyclical Mucosal Ulceration None of my cases had eye lesions, but do they therefore belong to a different nosological group ? As I pointed out in that article, there is no doubt that many single girls suffer with this condition but do not report the vaginal ulceration to their doctors, often because of false modesty

Eight young women doctors who suffer from this condition have consulted me about treatment, and all of them have informed me that they know many people who are also afflicted The great majority of the large number of patients whom I have seen have been single women The marital state of their patients is not mentioned by Dr Phillips and Dr Scott

I have also seen over 30 cases of recurrent buccal ulceration in young men, none of whom had either eye or genital lesions But surely these cases also belong to the same syndrome, call it what you will

London, W 1 M H PAPPWORTH

A BARBITURATE ANTAGONIST

SIR,—The case reported by Dr Montuschi and Dr Wickenden (March 19), coupled with Dr Harris's paper (Jan 22), prompts me to report a recent experience with β,β- methyl ethyl-gluterimide (NP 13) in the treatment of barbiturate poisoning

An obese woman, aged 53, swallowed phenobarbitone gr 72 at 3 30 P.M on March 11, and was admitted to hospital at 5 P M. She was then deeply comatose and completely flaccid and areflexic, with small non reacting pupils, blood-pressure 90/60 mm Hg, pulse rate 60 per min , and respiration-rate 20 per min Barbiturate was found in the stomach washings Penicillin was administered, and physiotherapy, with repeated laryngeal suction, was carried out throughout the illness The patient was fed by an intragastric drip, and a self retaining catheter was inserted into the bladder At 9 15 P M the patient responded to severely painful stimuli but otherwise her condition was unchanged Barbiturates were not detected in the urine

On the fourth day after admission pneumonia developed and extensive adventitious sounds appeared in the chest , the temperature rose to 100 8°F, the pulse rate to 116, and the respiration rate to 36 This infection gradually resolved On the fifth day (March 15) the deep tendon reflexes returned, and the cough and swallowing reflexes were clearly present Mild hypokalæmia (serum potassium 3 3 m eq per litre) developed, which responded to increased intragastric potassium. The urine contained a large amount of barbiturate

On March 16 some deterioration was obvious and the deep reflexes were absent At 8 P M NP 13 240 mg was administered intravenously over 90 minutes ('Daptazole ' was not available) There was some transient deepening of the respirations but no other change On March 17 the patient was somewhat less comatose , the reflexes were again easily elicited, and tests for urinary barbiturates were weakly positive It was decided not to administer a further dose of the drug, because of her improved condition Coma gradually decreased, and by the evening of March 21 the patient was fully conscious

It is obvious, in view of the account by Dr Montuschi and Dr. Wickenden, that the absence of clinical improvement in this instance was due to insufficient d but I felt that caution should be exercised in ad ing this relatively unknown drug

I wish to thank Dr C E Kellott, under whose patient was admitted, for permission to publish th and also Dr N A Wynn, of the department of phy King's College, for his interest and for supplying the

General Hospital
Newcastle upon Tyne MORGAN MCELLI

GENERAL PRACTITIONERS' HOLIDAY

SIR,—Consultants in the National Health Serv entitled to six weeks' holiday per year During th they are not obliged to find a deputy, or if they one they are not obliged to pay him

No such consideration has been given to the h of the general practitioner, who, if he takes one has to find and pay a locum Consequently, un can get a partner or colleague to do his work f he may not get much of a holiday And why partners or colleagues be called upon to do this when they usually have quite enough to do alread

As there are many unemployed doctors in the c could not the Ministry form a pool, and allow practitioners to call on it for locums—the M paying the fees ? This arrangement would all general practitioner to have a well-deserved holiday of six weeks like his consultant coll Or the six weeks could be limited to senior practit while the junior practitioners and the junior cons could have four weeks

Littlehampton,
Sussex HUGH STEW

HOSPITAL STAFFS

SIR,—It is not clear what Dr Dickinson (Mar seeks to gain by adding further irrelevancies to an tangled problem His basic fallacy is the assu that the pay of junior hospital staff and the c difficulties experienced by senior registrars in obt consultant posts are in some way related On the con the number of senior registrars (which is the crux problem) is determined not by their salaries, w over liberal or otherwise, but by such factors needs of the hospital service, the number of consul in-training judged appropriate to the specialty, ar financial capacity of the National Health Servic reduction in the pay of registrars, up to a point, only have the effect of diminishing the *initial fi* candidates for ultimate consultant status and cr a bias in favour of those who have private mea who are prepared either to forgo marriage or to and live on their wives There is no evidence tha of these types necessarily make better consu than do more ordinary mortals On the other reducing the pay of registrars beyond a critical leve achieve what Dr Dickinson apparently envisages equanimity—that is, an increasing number of registrarships throughout the hospital service T the matter in the simplest terms two major of the National Health Service at present are (*a*) diffi in obtaining registrars for the less attractive hos and (*b*) a superfluity of candidates for principalshi general practice How then can increasing the bias in favour of general practice redress the balance

Ideally, the pay of the registrar, as of every of the community, should accurately reflect the l and expense of his training, the value of his se the attractiveness of his job, and similar considera Discussion based on such premises can be of real and those who conscientiously believe that are paid more than they are worth are fully entitle state their case (and indeed it may be a good one) let them first make their case, not assume it , and them not then proceed to apply their hypothe problem with which it has at the moment not the motest concern.

I have written throughout in terms of registrars nce it can hardly be argued that an economic deterrent would be used to discourage candidates from applying for house-appointments.

St. Mary's Hospital,
London W 2.

H McC GILES

INACCURACY IN THE LABORATORY

SIR,—Dr Bassir is less than fair to the chemical pathology laboratories in this country in his letter of March 26. He states that only a few laboratories participated in the recent international survey to which your annotation referred and he implies that most biochemists are complacent in the present situation. The facts are that 40 British laboratories took part—a number limited only by the number of samples which it was possible to prepare (a total of 200 for distribution to all the countries concerned). As organiser of the survey, I had to refuse many people who wished to coöperate.

In reply to Dr Bassir's query about the clinical value of extra effort towards accurate results, it is apparent that the interpretation of results is made more difficult by a large observed biological variation. This is made up of two parts: the natural biological variation and the superadded analytical uncertainty. We may be able to do little or nothing about the former, but we should not make matters worse by analyses which are less precise than they should be.

There has also been some progress towards standardisation of methods. For a long time the Association of Clinical Pathologists has issued broadsheets of recommended methods (including chemical analyses), while the Society for Analytical Chemistry has compiled a bibliography of standard methods applicable to chemical pathology.[1] The American Association of Clinical Chemists has recently published volume I of *Standard Methods of Clinical Chemistry*,[2] and further volumes are in preparation. Such publications are, of course, in the nature of recommendations only, and the responsibility for the method used remains with the director of the laboratory. In many circumstances the recommended method may be inappropriate.

The committee which is analysing the freeze-dried samples of serum was jointly constituted by the Association of Clinical Pathologists and the Association of Clinical Biochemists. Its function is to keep the whole subject of chemical laboratory accuracy under review and make recommendations. The secretary is Dr E M Darmady, of the Central Laboratory, Milton Road, Portsmouth.

Postgraduate Medical
School, London W 12

I D P WOOTTON
Secretary, International
Association of Clinical Biochemists.

SIR,—In connection with Dr Jordan's letter of April 9, may I say that prior to the international survey with freeze-dried serum a general invitation was extended to all laboratories by Dr Wootton and Professor King[3] in these terms:

"We intend to look further into the comparability of results obtained in different laboratories both in terms of absolute values and proportionality of results, and to investigate the possibility of some system of regular checks. Any laboratory which is willing to participate is invited to communicate with us."

Area Pathology Laboratory,
Westwood Hospital,
Beverley, Yorks.

O BASSIR

HOLES, KNOBS, AND WIRES

SIR,—There is no doubt that hetero-suggestion and auto-suggestion play a part in determining our attitudes towards works of art. But the forces of suggestion are not peculiar to the world of art (abstract or representational); they are equally influential for our attitudes in all spheres of life—e.g., in politics, morals, religion, and philosophy. However, more worthy of debate is Sir Henry Turner's implication (April 9) that only representational art can give genuine and lasting æsthetic pleasure. He says, for example, that surrealism is faring better than purely abstract art because it "uses recognisable objects." His paper is, in fact, an attack on abstract art in general, *not merely the expression of a personal* dislike for "holes, knobs, and wires."

One does indeed still meet people who seem to believe that unless a painting or sculpture can show a recognisable dog, horse, man, or tree, it cannot possibly yield æsthetic pleasure. All the same it is an undeniable fact that certain (by no means all) combinations of straight and curved lines, dots and dashes, triangles and squares—yes, even holes, knobs, and wires—can produce an effectively pleasing design. It may be "meaningless" in the representational sense; its only meaning is that it gives æsthetic satisfaction, and is not this the sine qua non of art? It is true that much in modern art is atrocious, but this is not because it consists of "meaningless objects," as Sir Henry suggests, but because it is ugly in form, design, and colour.

Park Prewett Hospital,
Basingstoke.

I ATKIN

SIR,—Sir Henry Turner in his analysis of abstract art has unconsciously begged the question—unconsciously because he has not taken into account his own unconscious. Clearly he is an abstract artist without knowing it. Whence did he derive his prescription for his work of art? From his unconscious. This produced the title *Time Passing*, which is to be represented by "three (or more) upholsterer's coiled springs." The spiral is almost too respectable a symbol for time. Note the significance of "three (or more)": this introduces the three dimensions of space, and the "more" indicates their expansion to the four or multi-dimensional space-time continuum. The inverted and illuminated aquarium bowl is a composite symbol of the sky and water into which the creation was first differentiated.

Abstract art, Sir, has scored off Sir Henry! He has designed a work of cosmic significance. *Time Passing* portrays the Universe.

If this interpretation is the result of hypnosis,

I am, &c.

Peckham, S.E.

HYPNOTISED

THE HAIR OF THE PILONIDAL SINUS

SIR,—If a visitor from outer space alighted [illegible] coniferous tree and decided to investigate its origin, he would reason somewhat like this. The pine-tree has stuck in the ground, having arrived from outer space like the visitor himself. In this view the visitor would be fortified when he recalled the frictional forces with which he had to contend during his flight. Did not the branches of the pine tree point in the same direction as the fins of his rocket?

Professor Scarff and Mr Page's picturesque arguments in their letter last week, now based on trauma, now on suction, now on friction, are not supported by factual evidence. In 19[illegible] they wrote [illegible] The [illegible] fact requiring explanation [illegible] required [illegible] pilonidal sinus is why [illegible] stantially in two [illegible] and the appearance of [illegible] tion which they [illegible] made [illegible] by the [illegible] sinuses [illegible] several other [illegible]

Bibliography of Standard, Tentative and Recommended or Recognized Methods of Analysis. Cambridge, 1949.

Wootton, I. D. P., King, E. J. *Lancet*, 1953, i, 471.

Comparison of hairs in the pilonidal sinus with those in skin follicles reveals that the scales in the latter are more prominent Hence their frictional resistance must be greater If then the frictional forces are as potent as we are led to believe, how does *any* hair ever reach the surface of the skin ? Why does it not just curl up on its papilla and give up in despair ?

We are asked to believe in frictional movements between the sides of the natal cleft, with the best will in the world these are difficult to demonstrate We are asked to confirm the theory by rubbing a hair in our palms, in my hands this does not work And we are asked to believe that the demonstration of hair-bulbs and root-sheaths in the depths of a pilonidal sinus is a freak of mechanics Surely, Sir, to have filled "the one gap in the case for the acquired origin of natal-cleft pilonidal sinuses" few would make bold to claim ?

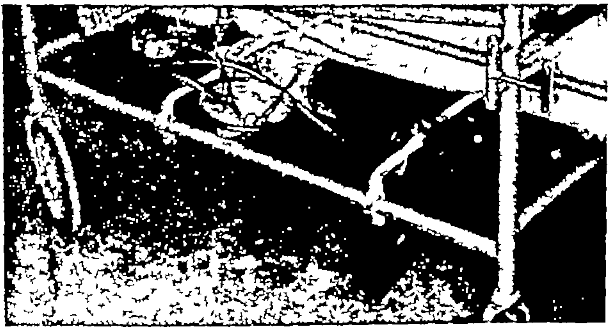
AN OXYGEN-CYLINDER CARRIER

Sir,—I was interested to see the oxygen cylinder carrier described by Dr Green and Mr Killick[1] A similar attachment has been in use on the *anæsthetic* trolleys at this hospital for about five years There is one useful addition—namely, a carrier for a stainless steel bowl to contain mouth-gag, tongue forceps, and swabs I suggest that manufacturers should consider making these as a standard fitment to all theatre trolleys



Solihull Hospital,
Birmingham.

BACKWARD IN READING

Sir,—Having long ago abandoned the mechanistic view of natural processes implicit in medical training for the organismic view, I adopt the same attitude to a reading disability in a child as I do to enuresis

All learning is a growth or maturation process The infant knows how to support his head on his neck and shoulders when, at approximately three months, his posterior neck muscles and the system of nerve with which they are integrated have matured sufficiently He stands walks, buttons his clothes, controls his bladder, and adds two and two when the organisation of brain, muscle, and gland have matured and differentiated to the extent necessary for these organised performances It is literally true that a child grows to read, as it is also true that he grows to control his bladder The rate of maturation of the organisation as a whole will be different in individual children and will also differ in respect of individual lines of development in the same child Experience suggests that the "norm" for bladder control by night is anywhere between a lower limit of three years and an upper of six or seven It is therefore as senseless to bring a child of three to a psychiatrist for "wetting" at night as to seek advice for inability to stand at six months As regards reading, Dundee Research Council found very many years ago that a child was not sufficiently mature to respond to formal phonic instruction in reading until he had reached a mental age of at least seven years

In ten years of child guidance under a local au I have dealt with several hundreds of cases of but I have never seen a case of delayed control th not already been subjected to mechanistic te punishment and reward or formal moralising In cases the child was charged with tensions induced punitive or anxious attitudes and personalities same applies in a modified form to my experi reading "disabilities" Where the previous histo attentively studied it will always be found that th child has been subjected to premature "training"

APPOINTMENTS IN THE WEST INDIES

Sir,—Recent issues of your journal have cont advertisements for specialist posts in the Col Medical Service (H M Overseas Medical Service many islands of the British West Indies Most of th posts call for specialist qualifications or experi The salary offered is on the average £1500, and may appeal to the person of registrar status ea around £1000–1300 in the United Kingdom, who anxieties as to his future in the National Health Se and may be enticed by the mention of "income at local rates" and by visions of sunshine

The advertisements do not mention the high cost of li in these islands—often as much as 50–75% higher than in U K In certain instances, a housing allowance is pro (maybe £100 p a), but in these cases it is virtually impo to obtain a suitable house for less than £250 p a In s places income tax rises to 7*s* 6*d* in the £ after £800 of tax income, and the allowances are similar to those in the U. Most appointees are rapidly disillusioned on arrival in particular Colony, and a few have cut their losses and retu to the U K. within a short time of arrival

I would strongly recommend intending applic for these posts to inquire carefully into the cost of liv the income tax rates, the housing difficulty, and conditions of local practice If at all possible, should obtain their information from someone on the s

TREATMENT OF SYPHILIS

Sir,—After your excellent leading article on subject[1] I should like to describe my observation treatment with penicillin of the later stages of la syphilis, and the possible Herxheimer reaction wh as you say, "cannot be prevented or diminished *starting with small doses of penicillin* The reacti of the 'all or none' type"

I administer 1,000,000 units of procaine penicillin G aqueous suspension daily for six days a week for two w and every second day in the third week—a total of 15,00 units of penicillin in three weeks In the first week I com in the same syringe with 1,000,000 units of procaine penicil 50 mg (2 ml) of cortisone acetate suspension ('Cort Merk), and in the second and third weeks 25 mg of suspension

In 87 consecutive cases there has been no Herxhei reaction Cortisone in the doses used does not inte at all with the treponemicidal effect of the penic because 1,000,000 units of procaine penicillin G is n above the minimal effective dose of penicillin my opinion this method helps also to prevent *dysfunction of vital internal organs, and especially o* cardiovascular system in the form of "therap paradox"

Thus, in summary, the combination of penicillin cortisone suspension (in the same syringe) permits treatment, prevents complications, including the H heimer reaction, and, in my view, makes obsolete preliminary administration of bismuth

RUPTURE OF THE DUODENAL STUMP AFTER GASTRECTOMY

SIR,—We read with interest the article by Mr Houson in your issue of March 10. We recently treated a case in which obstruction of the afferent loop occurred This obstruction was followed by gangrene of the loop but the duodenal stump remained intact

A man, aged 67 was admitted to the Metropolitan Hospital after a small hæmatemesis. A few hours after admission he had a further severe bleed. He was transfused and about 24 hours after he was first seen a partial gastrectomy of the Polya anti-colic type was done A large bleeding ulcer was found on the lesser curve.

Postoperatively the patient's condition was satisfactory Intermittent gastric suction through an indwelling Ryle's tube was used and bile was aspirated Fluids were given intravenously Oral fluids were started on the second postoperative day and the Ryle's tube was removed next day when his condition was satisfactory Late on this day he vomited and the tube was replaced On the fourth postoperative day he complained of severe abdominal pain which was colicky at times. Only a few millilitres of fluid was aspirated from his stomach and there was no bile in those aspirations. On examination there was no generalised distension but there was tenderness and guarding in the left upper quadrant of the abdomen Bowel sounds were normal By the following day there was a suggestion of a palpable mass in the left upper quadrant

Laparotomy was carried out on the sixth postoperative day An enormously distended loop of small intestine presented on the left side of the abdomen which was first thought to be the efferent loop but after decompression it was seen to be the afferent loop which had passed through the retro-anastomotic gap[1] The loop was gangrenous as far as the duodenojejunal junction and was resected Continuity was established by anastomosing duodenum to distal jejunum The patient died the same day

Post mortem examination confirmed that the duodenal stump was intact and in view of the condition of the bowel it is probable that untreated perforation of the afferent loop would have occurred rather than rupture of the stump

TUBERCULIN TESTS

SIR,—After reading your annotation of March 26 I feel more and more confused about the interpretation of a positive test. The W H O call many reactions to 100 T U non-specific you prefer non tuberculous If it can be shown (as I can) that school-children who have reacted to the jelly test (10 T U) (and were radiographed in consequence and thereby shown to have primary tuberculous infection in the thorax) have later failed to react to 100 T U then the W H O statement cannot always be true for these children must have passed through a phase of mild reaction to this concentration I know of a score of such positive X ray/negative Mantoux cases

Again in administering B C G by multiple puncture it was often observed that those pupils who were formerly positive to 10 T U., but who were now non reactive to 100 T U showed an earlier and more definite local vaccination reaction and were quickly rendered allergic—in seven days and sometimes less B C G (intradermal three or four years ago) reverters revaccinated by multiple puncture last week showed local reaction in forty-eight hours and allergy appeared simultaneously How are these phenomena explained if they were originally non tuberculous or non specific?

Regarding the bovine and avian mycobacteria it is interesting to note that only the human organism has been found in lesions in human beings in Lewis since 1940, when special steps were taken to type the organisms recovered from any tuberculous lesion

In 1949 I learned that hens dead of fowl pest had been found to have co-existing tuberculous lesions I tested a dozen hens and found one reactor and in 70 children who had reacted to the jelly test I did comparative Mantoux tests with P P D human and avian using 0·00002 mg Not all the children reacted to both: in 3 cases the erythema at the site of the avian test was somewhat more extensive than on the other arm where the human P P D had been injected

R STEVENSON DOIG

PARKINSONISM DURING TREATMENT WITH RESERPINE

SIR—As you observe in your leading article of March 12 reserpine the active alkaloid of *Rauwolfia serpentina* is being increasingly used in the treatment of hypertension and of psychiatric disorders[1 2] Clinical reports so far published have commented favourably on its lack of toxic effects. In the following cases, two inpatients receiving large doses of reserpine developed conditions clinically indistinguishable from parkinsonism which disappeared when the drug was discontinued.

CASE 1—A man aged 43 was admitted to hospital for treatment of a moderately severe obsessional and anxiety state which had been intermittently present for four years. On admission he was anxious, tense and mildly depressed and he had obsessional preoccupations with fears of insanity and of death. His blood pressure was 180/90 mm. Hg and he had a fine tremor of the outstretched fingers He improved somewhat after admission, and his residual symptoms were treated by reserpine (0·5 mg b.d for six weeks) During this time his condition changed very little although he put on 6 lb in weight When the reserpine was discontinued however his tension anxiety depression anorexia and obsessional symptoms returned. It was therefore decided to give him 15 mg of reserpine daily After four days he had become much more depressed and anorexic he was very restless, and he had suicidal ideas. He also had a fast coarse tremor of his trunk and limbs. The dose of reserpine was reduced to 7 5 mg daily and two days later his depression had markedly improved He was still restless and the tremor continued though it was less obvious Over the next five days he developed a mask like face and a bowed head on stooping shoulders, he complained of excessive salivation, and he did not swing his right arm on walking There was no rigidity Reserpine was thereupon stopped The tremor disappeared almost immediately and the facial expression became normally mobile within a fortnight but the patient did not swing his right arm freely for about six weeks. The original psychiatric symptoms returned within a week. The blood pressure was unchanged throughout.

EFFECT OF ANÆSTHESIA ON FIBRILLATION

SIR,—During an anæsthetic given for prostatectomy to an old man with auricular fibrillation (the anæsthetic including trichlorethylene), his fibrillation became intermittent and then stopped Rhythm, apart from a few extrasystoles, remained regular after 12 days

The patient, who was 79, was fibrillating slowly at about 80 beats a minute, and the blood pressure was around 170/80 mm Hg He had had digitalis folia (gr $^1/_2$ b d) for nine days, with no loading dose Premedication was pethidine (100 mg) and atropine (gr $^1/_{100}$) Thiopentone (0 25 g) and *d* tubocurarine (15 mg) (the latter repeated after cystoscopy) was followed by nitrous oxide, 40% oxygen, and 1–1$^1/_2$% trichlorethylene After 30 minutes, fibrillation became spasmodic (fast and very erratic), and 30 minutes later rhythm was completely normal at 60 a minute Shortly after this atropine gr $^1/_{100}$ raised the pulse to 120, and neostigmine 2$^1/_2$ mg hardly affected this

A patient with fibrillation may return to normal rhythm at any time Trichlorethylene is occasionally recorded as producing fibrillation Digitalis is likely to have been concerned in this case Stress may induce return to normal, and I wonder whether the marked response to atropine may be a hint that this was the main mechanism here

London, E 11

JOHN BARNARD

RABIES IN GERMANY

SIR,—Referring to the fourth reason in Mr Wells's letter of March 26 about why vaccination of dogs in Germany has been rejected, I suppose that some confusion has arisen In Germany the vaccinated dog is considered a source of danger, and this idea rests on the fact that a vaccinated dog is itself protected against clinical symptoms, but it is nevertheless possible that such a dog will secrete infectious saliva if it is contaminated subsequently

The Netherlands report on rabies in Western Germany, discussed in your annotation of Jan 1, has been published in its original form in the *Nederlandsch Tijdschrift voor Geneeskunde* [1]

Staatstoezicht op de Volksgezondheid

Obituary

ARTHUR FERGUSON MacCALLAN
C B E, M.D Camb, F R C S

As founder and director of the Ophthalmic Hospital of Egypt, and as ophthalmic surgeon to the Westminster Hospital and the Royal Eye Hospital, Mr MacCallan divided his career between two countries But in his particular subject his reputation was far wider, and was president of the International Trachoma Organisation

He was born in 1872, the son of the Rev J Ferguson MacCallan, vicar of New Basford, Notts, and was educated at Charterhouse and Christ's College, Cambridge With a university exhibition he continued his medical studies at St Mary's Hospital, qualified in 1898, and took the F R C S in 1899 For three years he was house-surgeon at the Royal London Ophthalmic Hospital, Moorfields, and then became chief clinical assistant In 1903 his name was suggested to the professor of ophthalmology at Cairo as the most suitable man to organise the new Egyptian ophthalmological service, under the trust established by Sir Ernest Cassel, with the object of conducting a vigorous campaign against trachoma throughout the country On appointment his first step was t study the different phases of trachoma, and he suggeste that this could best be done by observing the children the government primary schools But it was only aft great administrative difficulties that he was allowed 1907 to undertake the treatment of 464 boys in a scho at Tanta. He was so impressed by the importance of th work that he later arranged for all the 70–80 Egypti *doctors to whom he taught ophthalmology to serve* a time at a school, for he held that the treatment *crowds of patients attending a hospital clinic irregula did not give nearly so much insight into the stages of t* disease

Besides training a corps of ophthalmic surgeons fr *among the young Egyptian doctors seconded to him* the department of public health, MacCallan had also set up a chain of provincial hospitals He successfu used ambulatory *hospitals to advertise the need f* permanent hospitals In remote parts he also found more practical to bring the treatment to the *patie* His Cambridge M.D thesis, for which he was *award* the Darwin prize of his college, summed up his experien and described his system of classification by four stag It was published in 1913 as a monograph with the t *Trachoma and its complications in Egypt*

In 1912 by order of Lord Kitchener, then High Co missioner, MacCallan undertook a *survey of the inciden* of ankylostomiasis and bilharziasis in two provinces Egypt, and organised two travelling hospitals to d with these diseases As a result of this work he w *appointed, against his own wishes, head of the epidem* logical section of the department of public health in 19

When war broke out in 1914 he was on leave England, but he was ordered to return at once to Eg by Lord Kitchener In 1915 he reorganised the f ophthalmic hospitals in North Egypt to receive casual from the Gallipoli campaign, he also sent three of travelling ophthalmic hospitals to Ismailia and Suez receive Turkish wounded In 1916 he was *posted* senior medical officer, with the rank of major, R A M at the base at Mersa Matruh on the Mediterranean co *of the Western Desert province*

He returned to civil ophthalmic work in 1917, and 1923 the Egyptian government appointed him direc general of the epidemic services and general hospit but he resigned and returned to London, where he appointed ophthalmic surgeon to Westminster Hos and surgeon to the Royal Eye Hospital

But his interest and influence in Egypt continued, and in 1925 the Memorial Ophthalmic Laboratory at Giza near Cairo, was opened through his efforts as a memorial to the men of the Egyptian labour corps and camel transport corps who had fallen in the war of 1914–18 The original laboratory had been financed by the gifts of MacCallan's personal friends the new laboratory a fine modern building designed by Noel Dawson was planned and equipped internally with MacCallan s expert advice. His former pupils subscribed for a bronze bust of him by Doyle Jones, which was placed in the laboratory and unveiled by the British High Commissioner in 1931 His honours included appointment as O B E. in 1918 and C.B.E. in 1920 and membership of the Turkish Order of the Medjidieh (third class) and the Egyptian Order of the Nile (second class)

MacCallan took a prominent part in the international campaign against blindness, and he was elected president in 1935 of the International Organisation against Trachoma The following year he was given a seat ex officio on the International Council of Ophthalmology and he was re-elected to the presidency up to 1954 when he was elected honorary president for life

When MacCallan joined the staff of Westminster Hospital in 1924 he was nearly 53 years of age with an established reputation in the ophthalmological world

'It must be rare indeed,' writes A. A., ' that a hospital staff is called upon to welcome a newcomer substantially older than the majority of its members, yet MacCallan was rapidly incorporated and thoroughly enjoyed his thirteen years of close association When he retired in 1937 he was appointed consulting ophthalmic surgeon, and during the late war he returned for a period to act as supernumerary Slim with handsome clear-cut features and a placid expression he had an air of distinction to which care in dress and punctilious manners contributed. His diction his vocabulary his mannerisms were of a type—Charterhouse and Victorian Cambridge as a colleague expressed it A poor public speaker he became animated in individual conversation; and though only a few were admitted to his intimacy nobody could fail to recognise a desire to take every opportunity to perform a courtesy and kindness."

Of MacCallan's work in Egypt P D T R writes

"His battle against the trachoma virus was on a heroic ale. His personality was forthright and tireless, selfless, able nd enterprising so that he was ideally suited to driving rough the delays and inertia that had blocked progress in e development of health services in Egypt for centuries ast as founder of a succession of eye hospitals, and as eacher of a devoted *corps of Egyptian oculists he attained* he renown he so fully deserved

"His sense of duty was a constant companion from his arliest days in a Nottinghamshire vicarage to his later service chairman of his local parish council During the late war he eturned to carry the weight of the eye department at Westminster Hospital, then bereft of eye-surgeons, as well as being C.O. to his local Home Guard As a great personality he will e remembered by all who knew him—occasionally with awe or he was intolerant of inefficiency and obstruction but lways with affection and admiration—and by the countless ear blind of the Middle East with deep and well-deserved ratitude

Mr MacCallan married in 1918 Hester McNeil Boyd Carpenter whose father was Bishop of Ripon from 1884 to 1911 She survives him with two sons and a daughter He died on April 1 at the age of 82

Dr G F PETRIE

D W H writes: 'Petrie was by temperament a ecluse so appreciation of him must be restricted to the knowledge obtained in the short but sometimes highly ntertaining intervals when the barriers were down He had at least two qualities which were invaluable in ne so completely devoted to science as he The first as a profound respect for and deep knowledge of the nglish language This gave him a driving urge to imbue he young scientist who came under his direction with ome of his enthusiasm Many of us who have to edit cientific papers are at least now grateful for the memor ble midnight hours of discussion on the best way of xpressing it ' They led, I hope to an indelible improvement in our approach to the compilation and presentation of scientific data His second outstanding attribute was a keen power of observation By chance it did not lead to the fame of a Pasteur or a Fleming, but in this quality he was of their company Diffidence and a seemingly excessive caution might be regarded among his worst enemies He was a keen naturalist with a peculiar leaning for taxonomy With Sir John Ledingham he developed—late in life for a Scot—an ardent interest in golf I am eternally sorry that I missed the privilege of caddying for him. Even one such experience might have led to a much better understanding of his approach not only to the ball but to life He was a product of the Lister Institute, and like all of us who have had that honour, he was devoutly proud of it

Notes and News

A BILL FOR EMERGENCY TRANSPORT

In April of last year a resident on Ailsa Craig needed urgent medical attention, so on two occasions the local lifeboat was hired to take him to a doctor on the coast Ayrshire Executive Council had met the expense (amounting to £16) out of the local mileage fund, on the grounds that if the patient had not come to the doctor, the doctor would have had to go to the patient, and an arrangement existed whereby the hire of the lifeboat, in such circumstances, was paid out of the mileage fund for Ayrshire The Department of Health for Scotland, however, confirmed the view of its auditors that there was no provision under the Act for paying the cost of transporting a patient to a general practitioner Since the patient had not attended a hospital, the sum could not be charged to the ambulance service

The department suggested that the patient should be asked to pay, but this request he ignored Accordingly, the department recommended that the local medical committee be asked to agree to the item being paid out of the mileage fund for Ayrshire The local medical committee, however, refused to accept this proposal, and the executive council has now, at the suggestion of the Department of Health, made application for the amount to be made a first charge on the mileage fund for Scotland

AN UNSATISFACTORY PATIENT?

The Northern Ireland General Health Services Board has been considering (says the *Belfast News Letter* of March 31) the request of a woman and her family that the board should assign them to a doctor's list The woman was removed from her doctor's list at his request, and she has so far been unsuccessful in finding another doctor in the district willing to accept her and her children as patients The children are in need of medical care and she ha[illegible]ingly turned to the board for help The board [illegible]pted the recommendation of its advisory medical committee that the patient should be asked to make a further attempt to find a doctor, and if this failed that the secretary of the local medical committee should be approached to see whether some arrangement could be made The difficulty appeared to be, the committee added, that the patients refused to carry out their doctor's instructions on treatment

ical Aspects of Traffic Accidents

onference on this subject is to be held at McGill University, real, on May 4 and 5 Prof Wilder Penfield, O M, F R.S, ive the introductory address Further particulars may ad from Dr Harold Elliott, Queen Mary Veterans ital, 4565, Queen Mary Road, Montreal

nating Need for Doctors

Evidence is now being invited by the committee set up by Minister of Health and the Secretary of State for Scotland, he chairmanship of Mr Henry Willink, to estimate the number of medical practitioners and the appropriate f medical students Invitations are being sent to organisations, but the committee is also willing to written evidence from other sources. Any person to submit views should send them ttee's secretary, Mr Phillip Muston, Row, London, W 1

Guy's Hospital

On Friday, May 6, at 5 P M, at the Medical School, London S E 1, Prof J Z Young, F R S, will give the Fison lecture on Memory Processes

West Midlands Physicians Association

The spring meeting of this association will be held at the Warneford Hospital, Leamington Spa, on Saturday, May 7, at 11 A M

Medical Society for the Care of the Elderly

The annual general meeting of this society will be held at the Whittington Hospital, London, N 19, on May 6 and 7

General Board of Control for Scotland

Mr D B Donald, a principal in the Department of Health for Scotland, has been appointed secretary to the board in succession to Mr J A MacGregor, who has retired after 45 years in the service of the board.

International Congress of Comparative Pathology

This conference will be held in Lausanne from May 26 to 31 under the presidency of Professor Fluckiger, director of the Federal Veterinary Office Further particulars may be had from the general secretariat, 19 rue César Roux, Lausanne

Institute of Diseases of the Chest, London

Dr J G Scadding is to give clinical demonstrations at the institute (in the grounds of the Brompton Hospital, Fulham Road, S W 3) on Fridays at 5 P M from April 22 to July 8 They are open to doctors without fee

Mental After Care Association

The annual general meeting of this association is to be held at 3 P M, on Friday April 22, at Westminster School, Little Dean's Yard, London, S W 1 Dr Henry Yellowlees and Sir Percy Barter will speak

Claire Wand Fund

The trustees of this fund invite essays on Postgraduate Education of Newly Qualified Doctors in Preparation for Entry into General Practice

The competition is open to any qualified doctor and the first prize is 200 guineas and the second prize 75 guineas The closing date is Jan 31, 1956 Further particulars may be had from the secretary of the fund, B.M.A House Tavistock Square London, W C.1

Royal Society

At a meeting of this society at Burlington House, London, W 1, on Thursday, May 12, at 4 30 P M, a film will be shown illustrating some of the research activities of the Istituto Superiore de Sanità in Rome Prof D Marotta, the director general, will give an introductory address, and Mr E M. Chain, F.R S, will speak on recent advances in carbohydrate metabolism

Premature Baby Unit

A small party was held at the Hammersmith Hospital on April 5 to welcome the 1000th baby to be admitted to the unit

The unit was opened on Dec. 1, 1947 Most of the babies cared for in the unit have been born in the obstetric department of the Hammersmith Hospital but over a third of admissions have been of babies born at home or in other hospitals and nursing homes. About 800 nurses from Great Britain and nineteen other countries have received periods of training

Human Relations in Industry

The Scientific Film Association is holding a conference on this subject from May 24 to 26 at Ashorne Hill, near Leamington Spa The four main sessions will be on films used as introduction to the job, films on human attitudes to work, films as a means of communication within industry, and films used for the training of management-worker relations Further particulars may be had from the general secretary of the association, 164, Shaftesbury Avenue, London, W C

Cushny Lectures

These lectures will be held at the Department of Pharmacology, University College, London, at 5 15 P M on Tuesdays and Fridays during May Dr S E Dicker will give the opening lecture on Renal Clearances in Mammalian Kidneys on Friday, April 29 The other speakers are Miss Gr Eggleton, D SC, Prof F R Winton, Dr Mary Pickford, Mr L E Bayliss, PH.D, Dr J D N Nabarro, Dr H. Harr Prof R A McCance, F.R S, Prof M L Rosenheim, and Prof G M Bull

TREATMENT OF TEMPORAL-LOBE EPILEPSY BY TEMPORAL LOBECTOMY

A SURVEY OF FINDINGS AND RESULTS

EPILEPSY of temporal lobe origin is common and often disabling and may not be controlled by anticonvulsant drugs. Sometimes it is caused by a tumour angioma, or cyst, and it may cease when this is excised More often, however the underlying lesion is microscopic in size and hard to detect by clinical or radiological studies, or even when the brain is exposed at operation Indeed the clinical pattern of the seizures and their association with epileptic electro-encephalographic (E E G) discharges in one or both temporal lobes may be the only guides.

In the three years preceding March 1954 we treated 31 patients, with intractable epilepsy of this type by resection of the responsible temporal lobe and obtained cure or considerable relief of the epilepsy in 26 In all but 2 of these cases E.E.G had disclosed an epileptic focus confined to or predominantly in, one temporal lobe and the neurological and radiological investigations had not provided certain evidence of a space-occupying lesion Most of our patients had also exhibited a personality change or even a psychosis. As in the majority the epilepsy appears to have been improved, and in many the personality disturbances as well we feel that this method of treatment warrants a more extended trial.

Historical Background

It was Hughlings Jackson (1888) who first pointed out the association of the dreamy state" and the auras of psychical experience, of epigastric sensations, and of smell and taste hallucinations with lesions of the temporal lobe Since then attention has been directed to the type of seizure which may be ushered in by any of these auras, and which is neither petit mal † nor grand mal (although it may be associated with these) but is characterised by brief periods of dazedness with confused or semipurposive behaviour and by masticatory or sniffing movements.

This type of seizure which has been described variously as uncinate epilepsy psychomotor epilepsy psychical epilepsy and epilepsy with an intellectual aura, has come to be recognised as a common manifestation of temporal lobe epilepsy In its milder form however a temporal lobe seizure may consist merely in a sudden brief appearance of the sensory aura without dazing and in more severe attacks it may develop into a grand mal convulsion (Lennox 1951 Gastaut 1953 Falconer 1954) Further in possibly half the cases the victims of temporal lobe epilepsy develop an associated personality disorder or even a psychosis (Gibbs 1951, Mulder and Daly 1952, Hill 1953 Falconer 1953, Pampiglione 1953b), and in this respect temporal lobe epilepsy stands in striking contrast to focal epilepsy arising elsewhere in the brain The personality disturbance may take various forms, and often as the fits come under control with medication, the behavioural disorder increases The fits and personality disorder in patients under medical treatment thus often seem antithetic

An important advance in the recognition of this type of epilepsy resulted from E.E.G (Gibbs et al. 1948, Hill 1949, Jasper et al 1951 Gastaut 1953) Indeed foci of epileptic discharges can be demonstrated in one or both temporal lobes in from a quarter to a third of all patients with epilepsy This advance paved the way for the surgical treatment of otherwise intractable epilepsy by removal of the affected temporal lobe, especially when the E.E.G abnormality was confined to that lobe During the past four years several neurosurgical centres have reported their experiences of anterior temporal lobectomy in such circumstances and the published results have been encouraging especially as regards the control of the epilepsy but also as regards the amelioration of any associated personality disorder

Wilder Penfield in Canada is the chief pioneer in this field of surgery For many years his policy has been to submit patients with intractable epilepsy of various types to detailed neurological radiological, and E.E.G investigations, and to select for operation those in whom these preliminary investigations suggest a focal lesion (Penfield and Erickson 1941) Patients with pronounced psychological disturbances have been excluded (Penfield and Jasper 1954) The cranial operation has been performed under local anæsthesia to enable the surgeon to stimulate various parts of the cerebral cortex with electrical pulses while the patient is conscious, and so to ascertain from which regions of the brain the epileptic aura or even the epileptic fit can be provoked Penfield and Jasper (1954) have also taken electrical records from the exposed brain (electrocorticography) as an additional method of localisation.

Until very recently Penfield was loth to excise any part of the brain unless either an aura had been provoked from it, or there was some visible abnormality such as a scar an atrophic gyrus, or a small cyst Thus, Penfield and Flanigin (1950) reported that in 68 patients operated on between 1939 and 1949 macroscopic abnormalities had been observed in the great majority of cases: cortical excision had been carried out on E.E.G evidence in only 3 cases where there was no visible abnormality and in 7 cases no cortical excision had been done because no lesion was recognised and no aura or seizure provoked Although in 32 cases half or more of the temporal lobe was removed, the excisions generally did not include the deeper parts of the lobe such as the uncus, the amygdala, and the Ammon's horn (hippocampus). In the subgroup of 55 patients in which the epileptogenic focus was apparently identified success (i.e cure or only occasional seizures) was obtained in 29 and in a further 16 the frequency of seizures was lessened by at least half None of the patien who underwent craniotomy without excision was benefited and of the whole 68 patients only 1 died. Even after removal of the greater part of the temporal lobe Penfield and Flanigin found no alteration in behaviour no particular loss of memory no persisting aphasia and no defect in initiative or in capacity for decision.

Morris (1950) Bailey and Gibbs (1951) and Green et al (1951) all in the United States, were responsible for the nex advance—namely the removal of the affected temporal lobe o E.E.G evidence alone Unlike Penfield these workers include patients from mental hospitals, who had personality disorder as well as epilepsy Consequently they were forced to operat on their patients under general anæsthesia and were thereb precluded from studying the effects of stimulation in consciou patients as Penfield did. General anæsthesia in some patient proved advantageous, for it often increased the spike-di charges from the abnormal areas. Bailey and Gibbs (195 usually removed the greater part of the temporal lobe anteri to Labbé's (inferior anastomotic) vein, but spared the hip campal gyrus, the uncus the amygdala, and the Ammo horn. Morris (1950) performed a slightly less extensive op

† This term is used here in the traditional sense of minimal seizures irrespective of the accompanying electro-encephalographic pattern.

6869

tion Green et al (1951), however, usually removed both the hippocampal gyrus and the uncus

More recently Bailey et al (1953) reported their collective experiences in 64 patients with both epilepsy and personality disorders In 33 of their patients the E.E.G abnormality was unilateral, and temporal lobectomy on this side abolished the seizures in 21 and much improved the psychological state in 15, enabling 14 to be rehabilitated In their remaining 31 cases spike discharging foci were observed in both temporal lobes, and after unilateral temporal lobectomy on the side of the dominant focus 7 patients were rendered free from seizures, and in only 3 was the psychiatric state sufficiently improved for the patients to be rehabilitated.

Workers at other neurosurgical centres have also reported their experiences, including Petit Dutaillis et al (1953) in France, Obrador (1953) in Spain, and our own group (Hill 1953, Falconer 1953, Pampiglione 1953b, Falconer et al 1953, Falconer 1954, Mitchell et al 1954)

The general experience has been that, as regards rehabilitation of patients, the surgery of temporal-lobe epilepsy compares favourably with the surgery of brain tumours or psychosurgery

Most of these neurosurgeons have performed these lobectomies by excising the superficial temporal gyri and then sucking out the deeper convolutions Usually the deepest parts of the temporal lobe, comprising the Ammon's horn, the amygdala, the uncus, and the hippocampal gyrus, have been left in situ Reports on the pathological changes present in the depths of the lobe have therefore been based on macroscopic impressions reinforced sometimes by fragmentary biopsies Penfield and his colleagues (Earle et al 1953, Penfield and Jasper 1954) emphasise the need to remove the uncus and the hippocampal gyrus in addition to the more superficial parts of the lobe, and describe cases which were not benefited by a superficial removal but were improved when these deeper structures were removed at a second operation

These workers also claim that the common pathological lesion underlying temporal-lobe epilepsy is "incisural sclerosis," which may involve most of the temporal lobe but affects particularly the uncus, the hippocampal gyrus, and the anterior part of the superior temporal gyrus They state that this condition was observed in 100 (66%) of 151 patients submitted to operation, but do not specify whether this sclerosis also extended to the Ammon's horn They hold that it is caused principally by birth trauma, and suggest that, during parturition, the mesial portions of one or both temporal lobes may become herniated through the tentorial opening as the result of head moulding, the anterior choroidal artery then becomes compressed against the free edge of the tentorium, causing local anoxia, and the sclerosis that follows this local anoxia develops in later life into an epileptogenic lesion

This is an attractive hypothesis, but from our own thological studies we believe that other processes also en involve the temporal lobes and thus give rise to epsy, birth trauma not being the exclusive cause of sclerosis Later events in childhood and adult life, as convulsions complicating childhood fevers, ular lesions complicating infections, the cyanosis iated with severe whooping cough, and head ies play at least an equal rôle (Meyer et al 1954) therapeutic results of surgery in Penfield's larger more recent series of cases have not yet been shed

Selection of Cases

e 30 patients ‡ whose relevant clinical features are ed in table I were referred from two sources 23 came from the epileptic practice of a psychiatric (Maudsley Hospital) and the remainder from a hospital (Guy's Hospital) Hence it is perhaps not prising that all but 1 of them also had a definite ality disorder The sexes were equally represented ages, at the time of operation, varied from 2½ to 56 years with 1 patient in the first decade of life, 5 in the second 9 in the third, 4 in the fourth 9 in the fifth, and 2 in sixth decade In 14 patients the epilepsy had b during the first decade of life, in 8 during the second decade, and in the remaining 8 patients at variable times between the ages of 20 and 50

The types of seizures conformed to the usual pattern of temporal lobe epilepsy, and some of the case histories have already been published (Falconer 1954, Falconer et al 1953, Mitchell et al 1954) Each patient exhibited a variety of attacks Amnesic seizures without a major convulsion but associated with auras of an epigastric, olfactory, gustatory, cephalic, or psychical character (psychomotor attacks) occurred in all Many patients had also noticed that these auras sometimes appeared without any dazedness or amnesia Grand mal (major convulsive) seizures, however, had occurred in 12 patients several times, in 9 they could be excluded, and in the remaining 9 they had either been very occasional or else the history was not sufficiently comprehensive to exclude them

The character and severity of the associated personality disturbances also varied considerably 10 patients exhibited psychopathic behaviour of the aggressive impulsive type with associated irritability and emotional lability Paranoid symptoms were observed in 9, and hysterical, anxiety, and depressive features in 7 A characteristic feature was a long history of emotional disorder and of poor adaptation to social demands, work, and sexual life Psychotic episodes in association with fits, necessitating admission to observation wards or mental hospitals, had occurred in 7 2 patients had been confined in mental hospitals as certified patients for more than a year, and 3 had been in remand homes or before the courts because of antisocial behaviour

Most patients had been under medical supervision for many years, and their attacks had continued in spite of long and adequate trials of various anticonvulsants Exceptions, however, were 3 cases (nos 9, 20, and 30 in which the suspicion of tumour was aroused because the seizures had appeared only recently in an adult patient, because the temporal horn was slightly distorted in the pneumo encephalograms, or because the E.E.G showed irregular slow-wave activity in the temporal region In several other patients the preoperative radiological investigations indicated either a definite space-occupying lesion—e g, a tumour, and an angioma—or porencephaly, but, as the operation on these patients was limited to local excision of the lesion, they have been excluded from this present study The various patients which we have included in table I have now all been followed up for periods of one to four years

Methods of Study

Before operation, all our patients, besides having a comprehensive psychiatric assessment, were submitted to detailed neurological, electro encephalographic, and neuroradiological examinations These inquiries were always supplemented by interrogation of the relations as well as by summaries of the notes from other hospitals Many patients also underwent detailed psychometric tests

Neurological Findings

In most patients neither the neurological examination nor the analysis of the cerebrospinal fluid showed any significant abnormality There were, however, 3 exceptions Two patients (cases 7 and 18), both of whom had sustained severe closed head injuries, exhibited various residual cranial-nerve palsies, and an adolescent patient ase 17) presented an infantile hemiplegia which had ppeared at the age of 3 years as a complication of easles.

---

‡ unately the second patient on whom we operated died ly after operation our only fatality to date Although ioned in earlier communications (Hill 1953 Falconer 1953 iglione 1953b Meyer et al 1954) she has been excluded his review because there was no opportunity of observing [illegible] ave followed the operation had she

E G Findings

Each patient had been repeatedly examined, often ver many years with scalp electrodes placed in various ombinations over the convexity of the skull Generally uch routine studies disclosed spike or sharp wave dis harges around the sylvian inferior frontal or anterior r mid temporal regions Occasionally however such outine studies were indeterminate In all cases we found hat special E.E.G techniques were necessary before the bnormality could be clearly and properly located (Hill 1953 1955 Pampiglione 1953b) These techniques include the placing of needle electrodes beneath the *temporal lobes (sphenoidal electrodes), and a midline* basal lead (chin nasopharyngeal or nasal) in addition to the usual scalp leads over the convexity as well as the use of induced narcosis (resulting from either quinalbarbitone by mouth or thiopentone intravenously) for often the epileptic discharges become activated as the patient passes into sleep

In 28 of our 30 patients a definite spike or sharp wave discharging focus was demonstrated in the temporal regions (table I) In 19 patients the focus was confined to one side generally being apparently closer to the sphenoidal lead than to the leads over the temporal convexity

TABLE I—CLINICAL MATERIAL AND RESULTS OF OPERATION

			Clinical features						Pathological features			Postoperative Results			
Case no.	Sex	Age (year)	Age at onset of epilepsy (years)	Family history of epilepsy	Other possible causal factors	Grand mal in addition to psychomotor seizures	Personality disorder (P = psychosis)	Temporal-lobe E.E.G focus	Side of operation	Small macroscopic focal lesions	Sclerosis of Ammon's horn	Fits	Personality	E.E.G	Working ability (preoperative to postoperative)
1	F	5½	1½			–	++	Unilateral	L	Hemangioma calcificans		Free	Improved	Slightly improved	Infant→at school
3	M	25	18		Difficult birth and pugilism	++	++	Bilateral	R & L		–	Occasional—died 6 *months* after second lobectomy of grand mal status	Worse	Not better	Some→ none

31	F	[illegible]	1		Scarlatina, whooping cough, and otitis	–	+	Unilateral	R		+	Occasional	Slightly improved	Improved	Some→ full

The frequency of these discharges varied from only a few times in each record of half an hour's duration to a firing rate of more than 100 times a minute Sometimes *subsidiary discharges were also evident in the suprasylvian regions* In 9 *patients spike discharges were* evident in both temporal lobes, but there was a predominance on one side, and this side was selected for operation Cases in which equally active and independent discharging foci were present on the two sides were rejected for operation In the remaining 2 patients a focus of 5–6 cycles per sec was present in 1 (case 27), while no epileptic activity was observed in the other (case 20), even on several occasions In case 20, however, the fits were of recent onset, and pneumo encephalograms showed that, although there was no localised distortion of the ventricles, the septum lucidum was shifted 2 mm to the opposite side A tumour was suspected, but at operation no tumour was seen Temporal lobectomy was performed because the anterior temporal region looked pinker than normal and electrocorticography showed diminished electrical activity there The patient was subsequently relieved of seizures, and pathological examination disclosed a small infarct

Radiological Findings

Straight radiographs of the skull were usually normal, but in a quarter of the cases one half of the cranial cavity was slightly smaller than the other, owing particularly to smallness of the middle cranial fossa, and indicating a defect of development dating back to early childhood In cases 1 and 19 patchy calcification was visible near a vascular lesion Carotid arteriography was performed in a few patients, usually with normal findings, even in 2 with angioma Pneumo encephalography, however, proved more helpful, and was done in all the patients, care being taken to outline the temporal horns of the lateral ventricles Although cases with definite distortion of the ventricular outlines, indicating a space occupying lesion of an appreciable size, were excluded from our series, *close scrutiny of the films showed slight asymmetry* in a high proportion of cases Thus pneumo-encephalographic evidence of either a slight smallness of one cerebral hemisphere or a focal dilatation of one temporal horn was seen in half the cases Almost always these radiological signs were on the same side as the E E G focus, but in 4 cases (nos 5, 18, 28, and 30) they seemed to be divergent, the temporal horn on the side of the E E G focus appearing smaller In all 4 cases we operated on the side of the electrical abnormality, and our action proved correct, for in each case a small macro-copic lesion was found (hæmangioma calcificans 1, icatrix 1, oligodendroglioma 2), and subsequently the itients were relieved of epilepsy When, therefore, the entricular outlines are asymmetrical, and one wonders whether one side is slightly dilated or the other side ightly narrowed, the pneumo encephalographic appearances should be interpreted in the light of the electro-ncephalographic findings If the ventricle on the same ide as the focus is small, a tumour may be present

Conduct of Operation

rom the work of Penfield (Penfield and Erickson 1941, field and Rasmussen 1953) as well as from our own erience of tumour surgery, we knew that the temporal anterior to Labbé's (inferior anastomotic) vein can erally be removed, even on the dominant side, without ucing permanent aphasia At the outset we therefore pted the policy of removing in one piece as much of ffected temporal lobe as possible without harming the t In this way we hoped not only to eradicate the ogenic lesion but also to secure the tissue in a itable for detailed histological examination

a

ion is usually done under local analgesia but, if the patient is very apprehensive or difficult to control, general anæsthesia is used. (Endotracheal nitrous oxide, oxygen, and trichloroethylene constitute a useful *non-explosive* anæsthetic which disturbs the E.E G patterns but little and allows electrical equipment to be used without risk of an explosion.) An intravenous saline drip *is set up so that during* electrocorticography an intravenous injection of thiopentone (0 10–0 15 g) can be given via the drip for its potentiating effects Also, if the operation has been started under local analgesia, its later *painful stages* can readily be completed under intravenous anæsthesia The pain incidental to the later stages of removal of the temporal lobe can also be lessened by injecting the gasserian ganglion with a *local* analgesic solution (Penfield and Baldwin 1952)

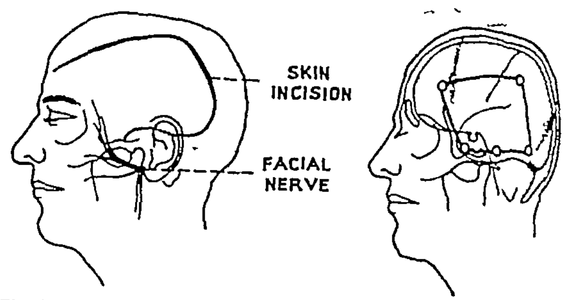

Fig 1—Siting of scalp and bone flaps for anterior temporal lobectomy

Incision and Bone Flap

The positions of the scalp incision and of the bone flap are shown in fig 1 The use of this particular incision avoids damage to the uppermost branches of the facial nerve, and the bone flap pedicled on the temporal muscle affords a maximum exposure of the temporal lobe and of the adjacent portions of the frontal and parietal lobes Occasionally an unsuspected lesion, such as a tumour or an angioma, will then present, in which *case it should be excised Usually, however, the surface* of the brain looks normal, although fairly often the temporal lobe looks small

Electrocorticography

This is not essential if the preoperative E.E G studies have been adequate , for an anterior temporal lobectomy can be confidently done on their evidence alone It is, however, very helpful in confirming the site of the focus and the presence of any abnormal cerebral tissue

Flexible electrodes (insulated except for their tips) are placed underneath the temporal and frontal lobes and at the temporal pole, and several standard electrodes are placed over the surface of the exposed brain A common finding is of spike discharges located at the pole, at the convexity close to the pole, or in the anterior part of the hippocampal gyrus In some cases spike discharges may also be observed outside the projected area of the excision—e g , in the posterior temporal and suprasylvian regions The significance of such discharges is not known, but our experience so far *indicates that, provided the main focal abnormality lies within* the part of the lobe which is to be excised, relief or improvement of the epilepsy can subsequently be expected. A most useful finding is that of areas where fast rhythm activity is not induced when intravenous thiopentone 0 10–0 15 g is given Such areas are found fairly often in the anterior temporal region and suggest the presence of diseased cerebral tissue in the vicinity (Pampiglione 1953a) Indeed it is our impression that such areas, if present, give a better clue to the location of the underlying pathological lesion than do *areas of frequent spike-discharges*

Stimulation Tests

In patients operated on under local analgesia we have then stimulated various parts of the temporal lobe with a pulsating electric current, as does Penfield In several instances we have provoked hallucinatory phenomena from the temporal lobe, but not consistently We have found, however, that local epileptic discharges, which are sometimes associated with ictal phenomena, can be induced from various parts of the cortex both in and remote from the temporal lobe, as well as from the region of the Ammon's horn (hippocampus) and the amygdala. The induced seizures sometimes resemble the patient's spontaneous seizures or they may differ. The induction of an aura or a brief seizure therefore from a point on the cortex, should not be taken as evidence that that point was the site of the epileptogenic lesion unless the induced attack is identical with the spontaneous seizures.

Technique of Operation

The steps of our operative excision are outlined in fig 2. The extent of this resection is similar to that practised by Penfield (Penfield and Baldwin 1952), but instead of removing the deeper parts of the temporal lobe by suction we try to excise the lobe in one piece. We also now spare more of the superior temporal convolution than we did originally (Falconer 1953), both to obviate aphasia and because this gyrus usually seems free from pathological change.

Starting at the sylvian point the incision runs obliquely to the inferior border of the lobe just in front of Labbé's (inferior anastomotic) vein a distance of usually 6–7 cm. from the pole. It is then deepened to uncover the lower and anterior portion of the insula (island of Reil). The section of white matter is made with a fine bore metal sucker (2–3 mm in diameter) hæmostasis being secured by finely controlled diathermy. The surface of the insula is protected by leaving in situ the pia mater investing the temporal operculum. Next the white matter between the lower border of the insula and the roof of the temporal horn is divided thus laying open the temporal horn with the Ammon's horn in its floor and the choroid plexus above this. The removal of the lobe is then completed by continuing the incision across the hinder end of the Ammon's horn on to its medial border and by dividing the most medial portion of the uncus and the fimbria hippocampi. During this last stage care is taken to keep inside the pial covering of the uncus and the hippocampal region to avoid damage to the third cranial nerve the posterior cerebr artery and the mid brain. An attempt is made to include i the specimen much of the amygdalar complex which lies abov and medial to the tip of the temporal horn. In closing th craniotomy the dural incisions are sutured to prevent bloo from the bone and scalp flaps from seeping into the ventricul system.

Incidental Effects of Operation

Immediate Postoperative Effects

We had 1 death among more than 40 patients, an Penfield and Flanigin (1950) had 1 in 68. Although th postoperative convalescence has generally been smoot a few focal motor seizures, usually involving the fac have been observed in about a third of our patients a some time during the first ten days following operatio Penfield and Jasper (1954) report similar observation These seizures are presumably due to reactionary œdem in the brain bordering on the area of excision, and the occurrence does not indicate that the patient's pre operative seizure will persist or return. Again in mos patients after removal of the greater part of the le temporal lobe, transient aphasia occurs which disappear in a week or ten days. Transient diplopia, and occasionall even ptosis, both due presumably to traction on th third nerve during the elevation of the temporal lobe have been seen in a few patients but have alway disappeared.

Permanent Neurological Effects

Most patients exhibit a partial homonymous hemi anopia generally limited to the upper quadrants. Penfield (1954) states that, if the excision is limited to less than 6 cm from the temporal lobe no defect of the visual field results. If however 6 cm or more is removed, an upper quadrantic homonymous hemianopia results and if more than 8 cm is removed a complete homony mous hemianopia follows. Our own experience shows a much greater variation than this because 1 patient even after a 6-cm. excision showed a nearly complete homonymous hemianopia while others after an 8-cm excision showed scarcely any loss.

As regards speech, in a third of patients in whom the dominant temporal lobe has been removed there was a slight but permanent nominal aphasia. The [illegible] of the difficulty was usually apparent in naming [illegible] one of ten common objects. 2 patients have noticed their speech difficulty themselves but [illegible] has been appreciably [illegible] by them. Penfield [illegible] (1954) report [illegible] persistent aphasia [illegible] temporal lobe [illegible] part of the [illegible]

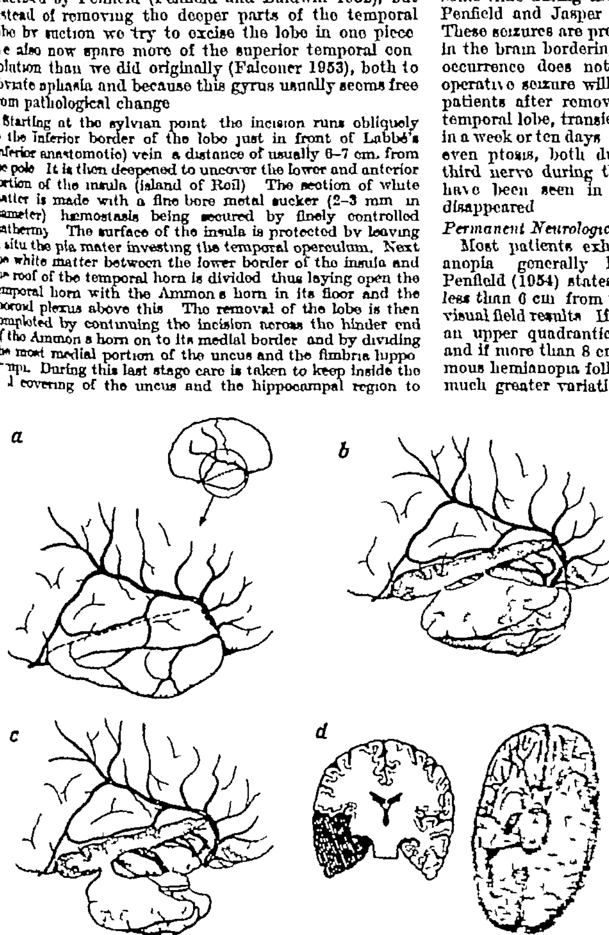

Fig. 2—Stages of temporal lobectomy: a, first stage showing the line of incision in relation to sylvian vessels and Labbé's vein; b, second stage, showing insula uncovered and temporal horn entered posteriorly; c, third stage showing temporal horn opened along its roof, Ammon's horn in its floor with choroidal plexus lying above it; d, representation of extent of removal of temporal lobe on completion of operation.

TABLE II—OVER ALL RESULTS OF OPERATION

As regards epilepsy (30 patients)			
Fit-free	12	Marked improvement	26
Occasional seizures only	14		
Still continuing fits, but frequency less		Slight benefit only	2
Improvement in epilepsy but not in personality or working ability (died later of grand mal status)			2
As regards personality disorder (29 patients)			
Much improvement	17	Definite benefit	20
Slight improvement	3		
No benefit or worse			9*
As regards working ability (30 patients)			
Regained full ability (including schooling)	14	Working	24
Partial improvement (no working ability to some)	5		
Previous ability to work unchanged (Full ability 3 some 2)	5		
Still no working ability			6*

* Includes the 2 patients who subsequently died of status epilepticus

(1955), however, have observed that, after removal of the dominant temporal lobe, there is usually a slight impairment in the patient's ability to learn new verbal material This difficulty is not present after removal of the non dominant temporal lobe It occurs even in the absence of aphasia Only 2 patients, however, have noticed it themselves one was a furniture packer (case 4) who found himself slow to learn new techniques of packing, and the other was a business man (case 9) who found it hard to describe his way through the streets of London, although he himself could find his own way, either on foot or by motor-car, without difficulty No difficulty exists in learning new material which is presented visually rather than auditorially

Therapeutic Effects of Operation

General

The salient data for our various patients are set out in table I, the follow up period varying from one to four years In assessing the results we have discounted any fits or behavioural disturbances observed during the early postoperative period Many patients have continued to take anticonvulsants, usually in smaller amounts than before, because our general policy has been to wait for two or more years' complete freedom from seizures before ceasing such medication altogether Several patients, however, ceased taking drugs on their own initiative, and a few did this without untoward effect, although 5 others exhibited an occasional fit (table III) One must remember, of course, that before operation all the patients had continued having fits in spite of regular and adequate medication

The over all results are summarised in table II They show that 26 patients were much benefited as regards their epilepsy, and 20 of the 29 who had a personality disorder were correspondingly improved Thus, whereas some improvement in the epilepsy was often observed, improvement in personality was less certain, and a third of the patients derived no benefit in this respect 12 patients are now fit-free, and 14 others have had occasional seizures The nature of these occasional seizures is summarised in table III, where it will be seen how frequently their appearance was related to the cessation of drugs, which were then generally reinstituted Of the 2 patients whose seizures were only slightly reduced case 7 showed radiological evidence of bilateral cortical atrophy following a severe head injury, and case 14 had a recrudescence of seizures during a pregnancy

As regards the postoperative psychological changes, in more than half our patients the improvement was striking, even in 3 of the 7 who had a psychosis Some patients whose epilepsy and concomitant mental difficulties have plagued them most of their lives need social measures or superficial psychotherapy to assist their timorous steps to establish themselves in a new and fit-free li [illegible] in all non analytic psychotherapy, precautions must be taken against a state of morbid dependency developing which will prevent rehabilitation of the patient In 5 patients (cases 7, 15, 23, 26, and 31) electroconvulsion therapy has been given for postoperative depressive states, and in 3 has been efficacious

Clinical improvement was often associated with improvements in the E.E G and in working capacity This last, however, more closely paralleled the changes in personality than the changes in the epilepsy Thus before operation only 3 patients had full working ability, and 15 had almost none After operation 24 are working and 17 have full working ability The 6 patients who are still not working are all handicapped by their persistent personality disorder rather than by epilepsy

In view of the often cited observations of Klüver and Bucy (1939) on the indiscriminate hypersexual behaviour shown by monkeys after bilateral temporal lobectomy, some observations on the sexual attitudes of our own patients may be pertinent

The necessary information could be obtained in 15 of our patients, and two clear patterns could be discerned those who did very well both in the epileptic and mental spheres showed an increase of sexuality by either intercourse or masturbation, and those who did poorly were impotent to various degrees Case 12 with fetishism (Mitchell et al 1954) and case 13 (Pond and Bidwell 1954) with sexual perversion were relieved of these disabilities Another patient (case 5) who masturbated openly several times a day and made homosexual advances during the second postoperative month, showed no improvement in his preoperative personality Our 1 patient with bilateral temporal lobectomy (case 3) has shown no sexual interest

TABLE III—ANALYSIS OF PATIENTS WITH OCCASIONAL FITS AFTER OPERATION

Case no	Follow up (years)	Particulars of fits
6	3½	Averages 4 amnesic seizures a year
10	2	2 amnesic seizures during first year
11	2	1 amnesic seizure recently on stopping drugs
16	1¾	2 minor focal motor seizures
18	1½	4 amnesic seizures on day of father's death
19	1½	1 amnesic seizure when drugs stopped abruptly
20	1½	5 amnesic seizures plus occasional olfactory hallucinations
23	1¼	Possibly 5–6 convulsive seizures but has not taken drugs
24	1¼	1 amnesic seizure at time of emotional stress
25	1	1 amnesic seizure recently plus occasional illusory sensations
26	1	1 amnesic seizure when off drugs plus auditory hallucinations on 3 occasions
28	1	Possibly 10 amnesic seizures, a reduction of more than 75%
29	1	1 amnesic seizure plus occasional dizzy sensations
31	1	1 focal motor seizure on stopping drugs

So far our experience of bilateral temporal lobectomy has been limited to 1 patient, who was not improved as regards personality, although after lobectomy on the second side he seemed relieved of his epilepsy Our patient exhibited a profound disturbance of memory but no aphasia He died, six months later, of status epilepticus Few details of similar cases have been published Scoville and his associates (Scoville 1954 Scoville et al 1953) report that after resection of the mesial portions of both temporal lobes in patients with mental illnesses but without epilepsy there is usually no great physiological or behavioural disturbance, although 1 of their patients suffered a grave loss of memory Bailey et al (1953) report having performed a two stage bilateral temporal lobectomy in 4 patients, of whom 2 were improved slightly and 2 were unchanged No-one has yet reported a case which was much benefited by bilateral temporal lobectomy

One other patient in our series (case 8) died of a grand mal status epilepticus twenty-five months after operation Until that time he had described himself as seizure free He had, however, a psychopathic personality which had not been improved, as well as a discharging focus in e opposite temporal lobe. Furthermore, towards the d of the first year he had presented a localised disten on of the operative cavity due to the development of a embrane across the cut end of the temporal horn with ontinued secretion of cerebrospinal fluid by the choroid lexus which had been left in situ. This distension had d to hemiparesis. The mechanism strongly suggested he local hydrocephalus of the temporal horn described y Cairns et al. (1947) as occasionally following gunshot ounds involving the trigone of one lateral ventricle. This complication so far has only occurred once in our experience, and it was treated by diathermy coagulation of the offending portion of the choroid plexus and was followed by an apparently successful recovery from the hemiparesis.

Correlation between Preoperative and Therapeutic Results

When the preoperative data were analysed in the light of these postoperative results, interesting correlations appeared (table IV). Such factors as age, sex, duration of symptoms, and whether the focus was on the right or left side were without obvious influence; but the presence of a second although subsidiary discharging focus on the opposite side and the occurrence of grand mal seizures (even only a few each year) definitely influenced the results for the worse. Repeated sphenoidal E.E.G. investigations under narcosis spaced over several weeks are necessary to exclude a contralateral focus. The best results were obtained in 13 cases in which the epileptic discharges were strictly confined to one temporal lobe and there had been only an occasional grand mal seizure or none. Every such patient was much benefited as regards his epilepsy and all but 1 as regards his personality also. This exception (case 6) is a man aged 45 with a history of psychomotor attacks and a paranoid personality disturbance dating back to early childhood. He has never had a satisfactory personality, and although employable he is still paranoid. It might be argued that, had this man been operated on while still in his teens or even earlier, the end result might have been better. To restore a normal personality to a patient who has not had one since early childhood might seem impossible; but this was accomplished in at least 2 patients (cases 13 and 21) who were operated on at the ages of 13 and 22.

A history of an occasional or uncertain attack of grand mal had little influence, for the results were no different from those obtained in cases in which grand mal could be excluded. The occurrence of separate bilateral discharging E.E.G. foci or of more frequent grand mal seizures (even only one or two each year) worsened the results slightly. But our worst results were when these two factors were combined, for in the 5 cases in which this conjunction occurred only 2 patients were benefited as regards epilepsy, and none as regards personality.

BLE IV—CORRELATIONS BETWEEN PREOPERATIVE DATA AND RESULTS OF OPERATION

Data	No of cases	Epilepsy		Personality disorder	
		Marked improvement	Little improvement	Definite benefit	No benefit
e of electro-encephalographic focus					
Unilateral	20	19	1	15	4
Bilateral	9	6	3†	3	6†
currence of grand mal					
No grand mal	8	8	0	6	1
Very occasional or uncertain grand mal	10	10	0	9	1
Grand mal	12	8	1†	3	†
ccurrence of electro-encephalographic focus with grand mal					
Unilateral focus with no, occasional or uncertain grand mal	13	13	0	11	1
Unilateral focus with grand mal	7	6	1	5	2
Bilateral focus with no, occasional or uncertain grand mal	4	4	0	3	1
Bilateral focus with grand mal	5	2	3†	0	5†

One patient had no personality disturbance either preoperatively or postoperatively.

Includes 2 patients who after apparent improvement died from grand mal status epilepticus.

Pathological Findings

In every case some pathological change of varying nature and degree was found in the resected temporal lobe. A preliminary report on this subject has only recently appeared (Meyer et al. 1954) and we shall therefore offer only a few generalisations. The pathological lesion has usually been microscopic rather than macroscopic; but the variety of lesions observed has been wide, in keeping with the long-established dictum that epilepsy depends more on the situation of a lesion than on its precise pathological nature, and that epilepsy can result from different processes.

In 9 cases a small macroscopic lesion was found (cerebral tumour 3, hæmangioma calcificans 2, angioma 2, infarct 1, cicatrix 1). The 2 cases of hæmangioma calcificans (cases 1 and 5) have already been reported (Falconer et al. 1953). These 9 cases, as might be expected since the whole lesion was excised, were all greatly benefited as regards epilepsy; but in 2 there was no corresponding improvement in personality. In 1 of these patients (case 18) there was radiological evidence of a widespread post-traumatic cerebral atrophy in addition to the localised cicatrix. In the other (case 11) a tiny capillary angioma was found in the uncal region, and this patient has continued to have a paranoid personality which has now lasted ten years. In this case, as in the other case of angioma (case 19), a second but subsidiary E.E.G. focus in the opposite temporal lobe disappeared after operation. Presumably the presence of such a focus in the opposite temporal lobe cannot be regarded as evidence of pathological change in that temporal lobe. In only 4 cases had we suspected from preoperative investigations that there might be a space-occupying lesion. In 2 of these (cases 9 and 30) pneumo-encephalography suggested slight indentation of the temporal horn; in the 3rd (case 1) an area of calcification was visible in the radiographs but without indentation of the temporal horn; and in the 4th (case 10) a calcified angioma had been removed from the superficial part of the temporal lobe at another neurosurgical unit, but the fits had continued without abatement. It was only after the deeper parts of the temporal lobe, including the uncus and the Ammon's horn, had been removed that her fits ceased and her personality was much improved.

In the remaining 21 cases the lesions were microscopic and less circumscribed. The complexity of these changes has been previously emphasised (Meyer et al. 1954) and the present analysis is no more clarifying. In all the cases the non-specific changes of meningeal fibrosis, focal or diffuse cortical atrophy, marginal gliosis, and gliosis of the white matter were present in various proportions. In 6 cases (cases 3, 7, 12, 14, 26, and 27) such lesions were the only ones observed, and the intensity of the changes was often comparatively slight. Degenerative arterial changes were prominent in case 29. In 12 of the 21 cases, however, sclerosis of the Ammon's horn was a conspicuous feature. In our more recent material we are learning that sclerosis and other changes may also be present in the amygdalar region. Pathological changes in this latter region have not hitherto been reported; but sclerosis of the Ammon's horn has been described by many observers during the past seventy years as occurring with this same degree in the brains of chronic epileptics who come to necropsy. The case material for most such studies, however, has usually been provided from institutions for chronic mental patients and so may well have contained a very high proportion of temporal-lobe epilepsy (Sano and Malamud 1953)

The ætiology of the various lesions in this subgroup of 21 cases with "microscopic" changes is obscure 6 patients had a known family history of epilepsy, and this proportion agrees with most published statistics regarding "idiopathic" epilepsy (Wilson 1940) It probably indicates a hereditary predisposition leading to lowering of the neuronal thresholds for epileptic activity rather than the actual inheritance of structural lesions Difficult birth was noted in 5 patients (a proportion which is undoubtedly of statistical significance) and precipitate birth was recorded in 3 other patients According to Penfield's hypothesis (Earle et al 1953, Penfield 1954) sclerosis of the Ammon's horn is due principally to birth trauma, whereas according to the classical view of Spielmeyer (1930) it is provoked by anoxia of the brain during the cyanotic stages of grand-mal seizures In our material, however, only 4 of our 12 patients with sclerosis of the Ammon's horn had had a pathological birth, and in 6 others the birth was reported as definitely normal In 7 cases grand-mal seizures had been observed, but in 4 they could be excluded A possible alternative cause in 4 patients had been a period of coma, cyanosis, or convulsions associated with an acute febrile illness in early childhood In 3 patients with sclerosis of the Ammon's horn no obvious cause was forthcoming Encephalitis did not appear to be a factor

Thus the pathological findings in our cases indicate that there is no one preponderant lesion in temporal-lobe epilepsy, but that the clinical picture can be provoked by different lesions due to differing causes

Illustrative Case-report

The case histories of several patients have already been reported (Falconer et al 1953, cases 1 and 5, Falconer 1954, cases 8, 13, and 20, Mitchell et al 1954, case 12, Pond and Bidwell 1954, case 13) The following case, not previously published, illustrates a striking recovery in both epilepsy and personality

Temporal lobe epilepsy, associated with a paranoid hallucinatory psychosis, relieved by anterior temporal lobectomy Pathological lesion sclerosis of Ammon's horn

Case 21—A woman, aged 22, referred by Dr L C Cook and Dr D M Lieberman, had had her first fit, a grand mal status epilepticus at the age of 19 months, a month after an apparently uncomplicated attack of whooping cough Her birth had been normal, and family history clear of epilepsy Shortly afterwards she started having frequent attacks of a psychomotor type without convulsions

The attacks usually began with an epigastric sensation, and in later childhood with also a vision of a "silvery man in armour" They would last from a few seconds to a few minutes, and during them she would appear frightened, wring her hands, and make swallowing movements In the longer attacks she became violent Various drugs had been tried but did not control the attacks, and between the ages of 7 and 12 years she was cared for in an epileptic colony From early life her personality had been abnormal she was liable to frequent temper tantrums and delinquency, and at times to sexual exhibitionism At puberty she had a schizoid personality, and this and her epilepsy rendered her unemployable During the past two years she had developed a paranoid hallucinatory psychosis She sat withdrawn and solitary, alternately smiling and grimacing, punctuating this with anxious glances, and listening to imaginary voices She said that people were controlling all her actions with wireless in the floor and roof, that people were always looking at her because she was a whore, and that other people were accusing her of stealing money She had attempted suicide and recently had been certified

On admission neurological examination was negative Repeated E E G examinations had always revealed a spike discharg[illegible]s in the left anterior temporal region, most clearly [illegible] the convexity but also evident at the sphenoidal lead Radiography of the skull and pneumo-encephalograms were normal

At operation the left temporal lobe appeared small, and electrocorticography confirmed the presence of spike discharges in the anterior temporal region The anterior 6 cm of the lobe was resected, gross sclerosis of the Ammon's horn being subsequently confirmed histologically, together with fairly heavy marginal gliosis and moderate gliosis of the white matter throughout the specimen.

Postoperatively the patient made a dramatic recovery She had two minor "blank" spells, coinciding with the first and second menstrual periods following operation, but subsequently she became seizure free She gradually lost all her hallucinations and became friendly and active in her home. Three months after operation she became a shop assistant, and seven months later she changed her occupation to that of agricultural worker Thirteen months after operation, when she reported back to hospital for review, she appeared shy but mentally normal, neat and careful of her appearance. She had given up her tablets several months previously Her work reports were good She had gained a stone in weight and looked robust and healthy Her menses, which previously had always been scanty and irregular, were now regular and normal Her only neurological sign was a right upper quadrantic homonymous hemianopia, which had persisted since operation The E.E G findings were considerably improved, focal spike discharges being no longer evident The patient and her family were delighted with her recovery

Discussion

The high frequency with which pathological changes have been found in the resected temporal lobes, and the high rate with which relief or improvement, particularly of epilepsy, has followed operation, suggest that the lesions observed and the symptoms relieved were related In those cases where discrete lesions were found in the temporal lobe, either of small space occupying character or of localised sclerosis, it seems likely that these lesions were the major factor in the production or continuance of the epilepsy, and more indirectly in the causation of the personality disorder The fact that with accessible space occupying lesions temporal lobectomy is not necessary, because mere excision of the space occupying le[illegible] generally relieves the epilepsy (Falconer 1954), favours such a view On the other hand, in cases where histological study suggests that the change in the temporal lobe may be only part of a general process, this question remains sub judice, for an alternative explanation may be th[illegible] we have relieved the epilepsy by interrupting important links in the neuronal circuits responsible for the production of a seizure

Case 17 is important in this connection because th[illegible] whole of one cerebral hemisphere was grossly diseased but only a temporal lobectomy was performed, and th[illegible] has apparently relieved the symptoms

This patient, referred by Dr Macdonald Critchley, h[illegible] developed a sudden right sided hemiplegia and aphasia at th[illegible] age of 3 years as a complication of measles Her spe[illegible] gradually returned, but she has since been backward, and gross infantile hemiplegia has persisted From the age [illegible] 4½ years she exhibited frequent psychomotor and grand m[illegible] seizures and became difficult to manage Pneumo enceph[illegible]graphy showed a much reduced left cerebral hemisphere w[illegible] considerable uniform enlargement of the left lateral ventric[illegible] Her clinical picture was thus of a type which nowadays [illegible] often considered for hemispherectomy, but we were chary [illegible] such a radical procedure because there was sparing of [illegible] fields of vision, and we could not tell whether her spe[illegible] functions were still located in the left hemisphere Furth[illegible] our E.E G studies, although they showed widespread abn[illegible]malities in both hemispheres, revealed spike discharges [illegible] in the left temporal region We therefore contented ours[illegible] with a temporal lobectomy, arguing that, if necessary, [illegible] could remove the rest of the hemisphere later The resec[illegible] specimen showed gross atrophy and gliosis of all th[illegible] convolutions and gross sclerosis of the Ammon's horn

Follow up since then has been by correspondence, but th[illegible] patient's father reports that she is seizure free, more amenab[illegible] and progressing better at her studies The girl is evident[illegible] still retarded but has learnt to write in English, which is er a foreign language Two explanations are possible for her mprovement: either the sclerosis of the Ammon s horn ather than the atrophy elsewhere was the epileptogenic rigger or the neuronal circuits underlying her seizures were nterrupted by the lobectomy

The frequency with which improvement took place postoperatively in our cases is greater than in most published series We feel that this is due to our policy of including the uncus and the Ammon s horn (and more recently the amygdala as well) in the tissue excised Certainly it is those regions which generally show the greatest pathological changes (5 of the small macroscopic lesions involved those regions in addition to the 12 cases of sclerosis of the Ammon s horn) The therapeutic results in case 10 in which the temporal lobe was excised in two stages support this view Penfield and Jasper (1954) describe an even more illuminating case which was not benefited by a superficial lobectomy but was relieved when the deeper structures were removed at a second operation

We are now on the threshold of a wide expansion in our knowledge understanding and therapeutic control of this ancient scourge of mankind. Various neurophysiologists have reported that in animals electrical stimulation of the hippocampal and amygdalar regions will produce behavioural changes and confusion similar to those observed in temporal lobe epilepsy in man (Gastaut 1953, Kaada et al 1953 1954 MacLean 1954) Similar disturbances can also be provoked by electrical stimulation of the Ammon s horn (or its vicinity ?) in patients at operation (Passouant et al 1954 Pampiglione Falconer and Mitchell unpublished observations) Our knowledge of the physiological functions of these structures is still very incomplete but it is receiving fresh impetus from these experiments on animals as well as from studies of patients with temporal lobe epilepsy

In pioneering any new form of therapy its sponsors must realise that several years must elapse before its merits can be accurately assessed In the past five years we have investigated many epileptics with temporal lobe seizures and it is only in some of these (probably less than half) that the criterion of a unilateral E.E.G focus or bilateral foci in which one side is predominant, can be upheld In many others evidence from the E.E.G of multiple cortical foci and of subcortical epileptic discharges are found All these have appeared unsuitable for surgery However in view of the grave disabilities shown by patients with severe and intractable temporal lobe epilepsy and their unresponsiveness to drug therapy the published results of temporal lobectomy in suitable cases are very encouraging It is therefore incumbent on us to persevere in this field especially as the operative risks are slight

Further developments are likely to be along the lines of better clinical recognition of this malady, of better understanding of its psychiatric aspects of better standardisation of E.E.G criteria for operation and of better correlation of the various clinical radiological and E.E.G changes in the light of the pathological findings It seems that good results are to be expected in any case of psychomotor ' epilepsy in which the focus is confined to one temporal lobe and major convulsive seizures have been absent or infrequent The prognosis for surgery worsens when grand mal becomes frequent or the focus becomes bilateral Early surgery should always be considered if there is a likelihood of an underlying cerebral tumour In other cases it should be considered if the seizures prove disabling and resistant to medication and especially if a personality disorder develops In many of our patients seizures had been present since early childhood but operation had not taken place until adult life One cannot help feeling that if through greater wisdom and knowledge it had been possible to operate on these patients earlier many years of wasted life would have been avoided

Summary

Of 30 patients with intractable temporal lobe epilepsy submitted to temporal lobectomy 12 became fit-free and 14 others greatly improved as regards their epilepsy 20 were benefited as regards their personality changes 17 markedly so

The historical background to the operation the basis of selection of patients the conduct of the surgical intervention, the various pathological findings, and the therapeutic and incidental effects of the operation are discussed

When society begins to invest academic work with a mystique and to regard the latter-day scholar as a latter-day priest then the university should respond by emphasising the relevance of knowledge to the problems of society, by coming into the market place demonstrating that science is only organised common sense encouraging the study of its applications debunking the expert And when society swings the other way and begins to undervalue pure scholarship to press for quick and tangible results, to let loose the Philistines on the university then the university should respond by withdrawing it should emphasise that the higher learning cannot be justified by profits or popularised without losing some of its precision it should remind society that the scholar must inevitably belong to an *élite* it should assert that there is a timeless quality about some kinds of knowledge Such an attitude as this may sound to be inconsistent and opportunist; but in point of fact for each succeeding climate of opinion such a response as this from the university would be perfectly consistent and anything but opportunist, indeed, it would put the university perpetually in opposition, as it were to the currents on the surface of society And I believe that is as it should be"—ERIC ASHBY D.SC *Listener*, March 17, 1955 p 468

BLOOD-AMMONIUM LEVELS IN LIVER DISEASE AND "HEPATIC COMA"

POSTGRADUATE MEDICAL SCHOOL OF LONDON

NEUROLOGICAL complications have been induced in patients with hepatic cirrhosis by the administration of large doses of ammonium chloride (van Caulaert et al 1932, Kirk 1936, Phillips et al 1952), and high blood-ammonium levels have been found during episodes of spontaneous hepatic coma complicating cirrhosis (Traeger et al 1954, Riddell and McDermott 1954, Sherlock et al 1954) In this paper we report blood-ammonium levels in a representative series of patients with liver disease with and without neurological changes An attempt has been made to determine the mechanism of the changes in blood-ammonium levels, and to assess the usefulness of blood-ammonium estimations as a routine clinical procedure

Case-material

We studied 66 patients with liver disease, 33 of whom showed neurological changes (table I), and 33 control subjects The latter were hospital staff and patients with chronic pulmonary or cardiac disease who had no clinical evidence of liver disease and normal liver-function tests

Methods

Neurological changes were similar, regardless of the ætiology of the liver disease The neurological status was graded as 0 (normal), 1 (minor disorder of consciousness and the motor system), 2 (gross disorder of consciousness and the motor system), or 3 (coma) Mental changes, which included apathy, confusion, inappropriate behaviour, and excitement, were regarded as the more sensitive index The common motor system signs were "flapping" tremor of the outstretched hands, altered muscle tone and tendon-reflexes, ankle clonus and extensor plantar responses

Impairment of liver function was assessed by clinical history, presence of jaundice and ascites, and serum-bilirubin and serum albumin levels

Extent of the portal venous collateral circulation was assessed clinically, by barium swallow, œsophagoscopy, and percutaneous transplenic venography (Atkinson et al 1955)

Venous catheterisation was used in 28 subjects to estimate the blood-ammonium levels in the hepatic and renal veins In the group without liver disease, readings were made when catheterisation was otherwise indicated for a necessary assessment of cardiovascular, metabolic, or renal function In 7 instances portal vein blood was obtained from abdominal-wall-collateral veins or at operation

TABLE I—PATIENTS STUDIED

Disease	No of cases	No with neurological complications
Acute icteric virus hepatitis	16	8
Portal cirrhosis	42	20
Biliary cirrhosis	5	2
Obstruction to hepatic veins	1	1
Low-output cardiac failure with hepatic necrosis	1	1
Obstructive jaundice with hepatic malignant deposits	1	1
Extrahepatic obstruction to portal vein	2	0

Blood ammonium levels were determined by Conway's (1950) microdiffusion method

0 5 ml of blood was delivered from a calibrated straight bore pipette into the outer chamber of a scrupulously clean Conway unit containing 1 ml of saturated potassium carbonate. A well greased lid covered the unit, and the ammonia liberated by the alkali was absorbed by 0 7 ml of $\frac{N}{4000}$ HCl in the central chamber during 15 minutes' incubation Using Tashiro's indicator, residual HCl was titrated with $\frac{N}{4000}$ Ba(OH)$_2$ delivered from a microburette Results were calculated as described by Conway and expressed in microgrammes of ammonium nitrogen per ml of blood

There is probably no measurable free ammonium in normal circulating blood (Conway 1950) but it is liberated very rapidly after shedding The observation of Conway and Cooke (1939) and Strehler et al (1942) that carbon dioxide prevents the liberation of ammonia was not confirmed, and 6 serial estimations were made on each blood sample in air These represent points on an asymptotic curve of ammonium concentration (White et al 1955)

TABLE II—BLOOD AMMONIUM LEVELS DETERMINED IN HEALTHY PEOPLE BY MODIFICATIONS OF CONWAY PROCEDURE

Reference	Preservative	Time between shedding and introduction into unit	Diffusion time (minutes)	No of observations	Mean blood ammonium nitrogen (µg per ml)	S.D.
Mann et al (1954)	None	30–40 min	60	21	1 14*	0·37*
McDermott and Adams (1954)	None	"Rapid"	10	10	0 61	0·10*
Singh et al (1954)	CO$_2$ and low temperature	10 min	?	34	0 11	0·03
Traeger et al (1954)	CO$_2$	"Rapid"	60	23	1 2	0·43*
Present work	None	40 sec	15	33	0 77	0·12

* Calculated from histograms given in text

Each estimation was timed from the moment of beginning the collection of blood until an aliquot was pipetted into the chamber Conway found progressive liberation of ammonium from exposed blood, and it is therefore imperative to pipette the blood rapidly It was possible to introduce an aliquot into the chamber in less than 40 seconds after withdrawal. Although zero time ammonium may be most significant, estimation of this depends on back extrapolation from only two points By 3 minutes, ammonium concentration had reached a maximum, and this value was chosen as most reliable and representative We did 3 estimations before and 3 after this time, and we have considerable confidence in this value, although values after the maximum had been reached occasionally deviated by as much as 0 1 µg per ml

Table II compares values obtained in healthy people with those obtained by other workers using the same method Large discrepancies are observed either when standards are not run simultaneously or when the blood is not pipetted immediately Older methods, which give very variable values for blood ammonium, are well reviewed by Bénard and Gajdos (1952)

Blood-ammonium Levels in Virus Hepatitis and Cirrhosis

In control subjects the mean peripheral-vein blood ammonium level was 0 77 µg per ml of ammonium nitrogen, and the value never exceeded 1 00 µg per ml The mean hepatic-vein blood ammonium level was 0 74 µg per ml (fig 1)

In virus hepatitis the mean peripheral vein blood-ammonium levels were higher than in normal subjects

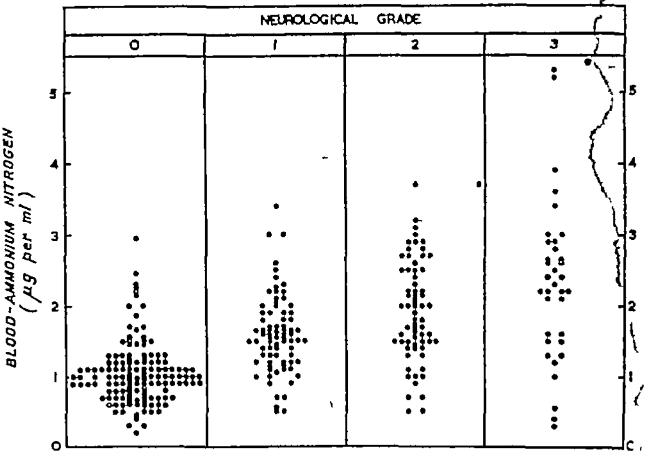

Fig 2—Blood-ammonium levels related to grade of neurological disability Solid circles neurological signs present or past ; open circles no neurological signs.

but this was due to the high levels found in patients with neurological complications no deviation from normal being found in uncomplicated cases (fig 1) The blood ammonium level was always higher in the hepatic vein than in the peripheral vein

In cirrhosis of the liver the mean peripheral vein blood ammonium level was raised slightly in patients without neurological complications and significantly in patients with them. The mean level in the peripheral vein exceeded that in the hepatic vein (fig 1)

In both hepatitis and cirrhosis the scatter was wide, and 3 patients with hepatitis and 2 with cirrhosis all with neurological complications showed little or no rise in the blood ammonium level.

In 6 of 7 subjects the blood ammonium level was much higher in the portal vein than in the peripheral vein The other blood sample came from a gastric vein High values were also common in the right renal vein (fig 1)

These observations support the conclusions previously reported (Kirk 1936, White et al 1955) that portal blood and to a lesser extent renal blood are important sources of peripheral vein ammonium In patients with severe virus hepatitis the failing liver allows ammonium to pass into the peripheral blood. In patients with cirrhosis in addition to impaired hepatic function the collateral circulation delivers portal vein blood directly to the peripheral blood-stream before it can be metabolised by the liver

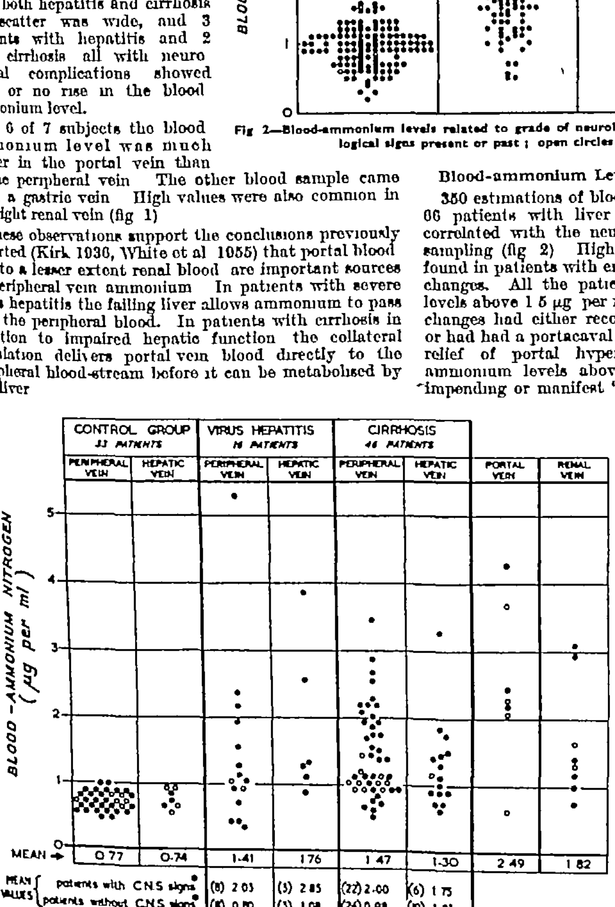

Fig. 1—Blood-ammonium levels in peripheral hepatic, renal and portal veins in controls and in liver disease.

Blood-ammonium Levels and Neurological Status

350 estimations of blood ammonium were made in the 66 patients with liver disease, and the values were correlated with the neurological status at the time of sampling (fig 2) Higher blood ammonium levels were found in patients with either present or past neurological changes. All the patients who had blood ammonium levels above 1 5 μg per ml but no objective neurological changes had either recovered from these complications or had had a portacaval anastomosis constructed for the relief of portal hypertension Those with blood ammonium levels above 2 0 μg per ml had either impending or manifest "hepatic coma" (*portal systemic encephalopathy*) at the time of sampling The proportion of patients with high levels rose as the neurological condition deteriorated However about 10% of estimations in each of the grades 1 2, and 3 were within the normal range

In individual patients the correlation of the blood ammonium levels with fluctuations in the neurological status was variable but never exact Estimations in 14 patients in terminal hepatic coma showed wide fluctuations unrelated to the neurological condition (fig 3) Of 38 estimations, 8 were within the normal range but in no patient was the blood ammonium level consistently normal This demonstrates the unsuitability of blood ammonium estimations in diagnosis, prognosis and assessment during terminal hepatic failure

In contrast 2 patients were studied with cirrhosis of the liver complicated by portal vein thrombosis and an extensive collateral circulation but only moderate impairment of

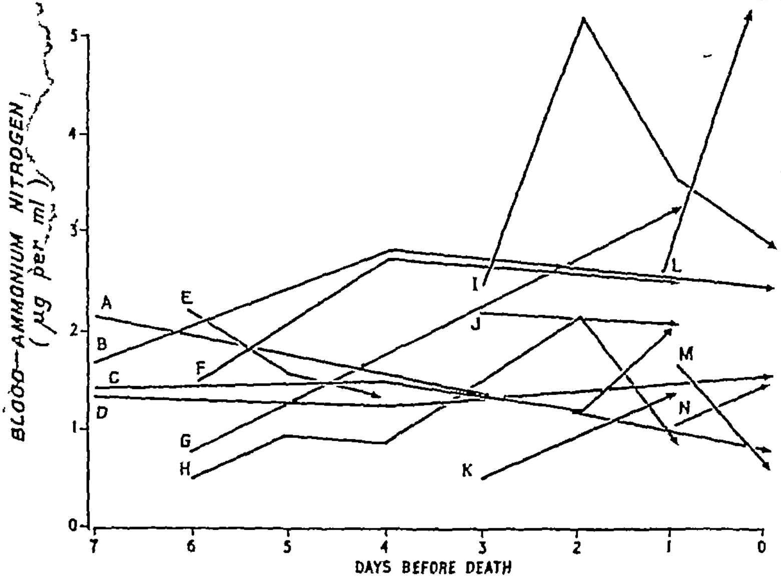

Fig 3—Blood-ammonium levels in 14 patients during last week of irreversible hepatic coma.

liver function Raised blood ammonium levels and neurological signs were always found

In case 1 (fig 4) the height of the blood ammonium correlated approximately with the severity of the neurological changes and with the therapeutic intake of nitrogenous substances (dietary protein, *dl*-methionine, and ammonium chloride) When ammonium chloride was administered, the blood ammonium level was raised for six days before neurological deterioration took place Eventually, on the twelfth day, the patient was still showing severe neurological changes, but the blood ammonium level was lower than on the previous two days. On the second occasion that ammonium chloride was given, the neurological status and the blood ammonium level improved simultaneously Worsening of the neurological status by oral *dl* methionine was associated with a rise in the blood-ammonium level

In case 2 (fig 5) there was again a fair correlation between the neurological condition and the blood ammonium level. During the first three weeks in hospital, restriction of dietary protein was followed by clinical improvement and a fall in the blood ammonium level As in case 1, therapeutic administration of ammonium chloride caused the blood ammonium level to rise before clinical deterioration took place, and again recovery coincided with a fall in the blood ammonium level. Following oral *dl* methionine, a relapse was associated with a rise in the blood ammonium level.

Blood-ammonium levels cannot be used to assess the long-term prognosis of patients with chronic liver disease and neurological complications We have observed consistently raised blood-ammonium levels for periods of three to ten months in 4 patients with cirrhosis and an extensive collateral circulation without any deterioration in neurological or hepatic function

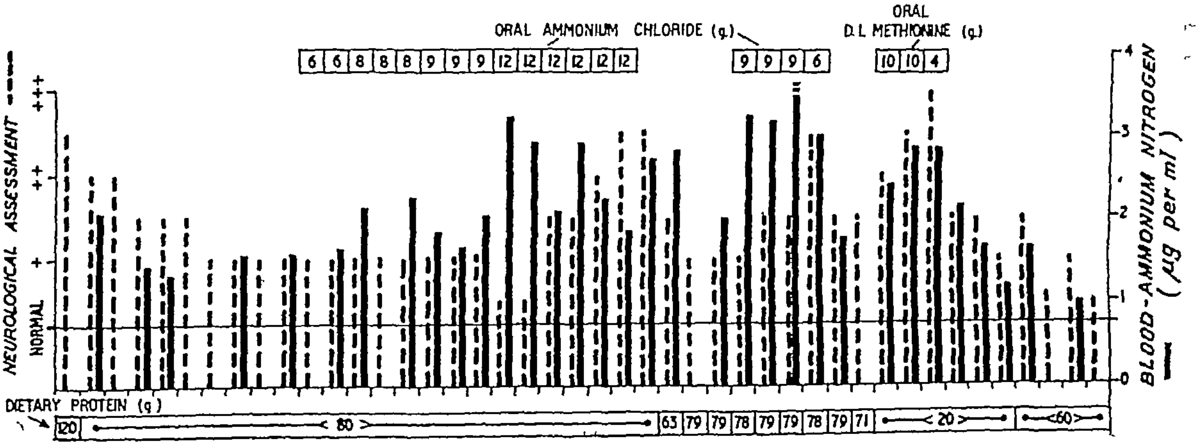

Fig 4

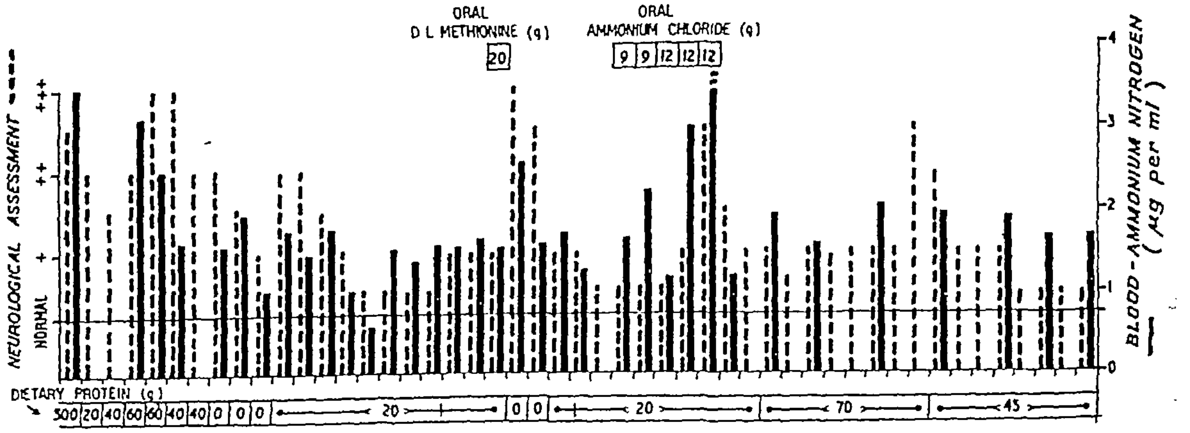

Fig 5

blood-ammonium levels in 2 patients with cirrhosis and persistent although variable neurological changes

TABLE III—BLOOD-AMMONIUM LEVELS IN PATIENTS WITH PORTAL-VEIN OCCLUSION AND GOOD LIVER FUNCTION

Case no	Sex	Age (yr)	Diagnosis	Serum bilirubin (mg per 100 ml.)	Serum albumin (g per 100 ml)	Blood ammonium nitrogen (µg per ml)
3	F	8	Congenital obliteration of portal vein	0 7	3·6	0 8
4	M	16	Pylephlebitis portal vein thrombosis	0 7	4 9	0 9
5	F	49	Cirrhosis thrombosed portal vein	0 9	3 7	0 8
6	M	55	Cirrhosis thrombosed portal vein	0 7	4 6	1 1
7	M	25	Cirrhosis thrombosed portal vein	1·0	4 1	1·0

Blood ammonium Levels in Relation to Portal Collateral Circulation and Hepatocellular Function

In 5 patients there was evidence of an extensive portal systemic shunt the liver was normal in 2 and in 3 there was histological evidence of cirrhosis, but liver function tests were normal (table III) Blood ammonium levels were not raised and there was no neurological change even after feeding increased dietary protein, methionine or ammonium chloride An extensive portal-systemic shunt is therefore not necessarily accompanied by either raised blood ammonium levels or neurological changes we have never seen these complications with a histologically normal liver, and there are no reports of them in the literature Blood-ammonium levels may be high in the absence of an extrahepatic portal collateral circulation in patients with severe virus hepatitis (fig 1)

Between these extremes, high blood ammonium levels may be found in patients with extensive portal collaterals and moderate hepatocellular failure and in patients with more severely impaired liver function and smaller collateral circulations. Therefore abnormal hepatic function is essential before the blood ammonium level rises, and this rise is greatly accentuated by the presence of a portal systemic collateral circulation

Discussion

Estimation of blood-ammonium has the disadvantage of uncertain specificity In fasting subjects without liver disease there is probably no measurable free ammonium in the circulating blood (Conway and Cooke 1939) Values represent points on ascending curves of ammonium liberation and include ammonium liberated during the breakdown of certain compounds in blood as well as "free" ammonium. Technical difficulties account for the different values obtained in various laboratories using the same basic Conway procedure (table I) Each laboratory must therefore determine its own normal value remembering that inaccuracies increase with the time allowed for evolution of ammonium after the shedding of blood The impossibility of preventing this liberation of ammonium from blood after it has been shed is a disadvantage and timed pipetting of blood into the Conway chamber must be done at the bedside The rapid serial estimations used in the present work reduce inaccuracies inherent in microtitration of ammonium but the procedure may be unreliable in the hands of laboratory assistants inexperienced in the method

Previous investigations have been confined largely to patients with cirrhosis, and the total number of estimations published is small Raised blood ammonium levels have been attributed to portal systemic shunting (Kirk 1936 Singh et al 1954 Mann et al 1954) but accurate assessment of the portal circulation has not been attempted. In our patients transplenic portal venography was used to assess the extent of the collateral circulation and it has been shown that mere shunting of portal blood with a high blood ammonium level into the systemic circulation is insufficient to raise the peripheral blood ammonium level if liver function is normal In virus hepatitis Traeger et al (1954) found normal blood ammonium levels in 5 patients, and Riddell and McDermott (1954) found a high blood ammonium level in 1 comatose patient In the present series a high level was found in 7 of 18 patients with virus hepatitis, of whom 6 had portal-systemic encephalopathy

Patients with neurological signs have a higher mean blood ammonium level than those with uncomplicated liver disease This finding applies to all groups regardless of ætiology Furthermore, when a large series is studied there is some association between the blood ammonium level and the severity of the nervous disorder, but there are exceptions These observations however can rarely be applied to individual patients. In acute terminal cases where death in coma is due to liver failure, no relation between blood-ammonium levels and the neurological changes is found although the blood ammonium may be raised this is not always above normal and varies widely In patients with persistent neurological signs on a controlled diet there is often a correlation between blood ammonium level and neurological status all these patients having large portal systemic collateral channels and only slight impairment of liver function They form a fascinating but restricted aspect of the problem of hepatic coma

The clinical value of blood ammonium estimation is therefore limited If the level is above 2 µg per ml (twice the upper limit of normal) the patient will be either suffering or recovering from the neurological complications of liver disease If it is below 2 µg, few useful conclusions can be drawn in diagnosing neurological changes and coma either in a patient with known liver disease or where evidence of liver disorder is equivocal Early diagnosis is made more readily by the clinical picture of personality change, "flapping" tremor on sustained posture, increased tendon reflexes with rigidity and usually flexor plantar responses (Adams and Foley 1953) The estimation of blood-ammonium has no place in prognosis and is not a practical test of liver function

Nevertheless the blood ammonium level in liver disease is of considerable theoretical interest In patients with liver disease a high blood ammonium level is mainly of intestinal origin ammonium reaching the systemic circulation by portal systemic venous channels and/or passing through a damaged liver Ammonium may be of importance in the pathogenesis of hepatic coma When ammonium chloride is given by mouth or intravenously to some patients with cirrhosis, the characteristic neurological changes of liver disease are reproduced (Phillips et al 1952, Seegmiller et al 1954) However these neurological changes can occur without significant raising of the blood ammonium level, and this discrepancy demands consideration From the clinical standpoint disadvantages have already been mentioned On theoretical grounds it might be possible for intracellular intoxication with ammonium to occur in the brain when normal peripheral vein blood ammonium values are found by current unsatisfactory techniques Alternatively, blood ammonium levels may reflect only the amount of portal venous blood reaching the systemic circulation without being adequately metabolized by the liver Portal blood might contain some toxic factor at present unknown Identical neurological changes can be precipitated by administering oral methionine without producing a constant rise in the blood ammonium level (Phear et al 1955) The relation of blood ammonium levels to liver coma might thus be similar to the relation of blood urea levels to clinical uræmia (Singh et al 1954): in both cases a correlation can be established, but in neither is the relationship causal

Summary

350 blood ammonium estimations were made on 66 patients with liver disease of whom 33 showed neurological complications, including hepatic coma

High blood-ammonium levels could be related to impaired hepatocellular function and a portal-venous collateral circulation Raised levels were found in some patients with severe virus hepatitis without a collateral circulation, but extrahepatic portal-venous obstruction with good liver function were compatible with normal values In cirrhosis raised levels could be attributed to both, the collateral circulation and impaired liver function

In patients with neurological changes, the blood-ammonium levels were usually correlated with the severity of the neurological disturbance, but 10% of values were in the normal range regardless of the degree of neurological involvement Levels above 2 µg per ml (twice the upper limit of normal) were invariably associated with neurological changes

The technique of estimating blood ammonium levels has both theoretical and practical disadvantages It cannot be recommended as a routine method of diagnosing the neurological complications of liver disease (particularly hepatic coma) or of assessing prognosis Once the clinician is familiar with the clinical sequence it is unmistakable

The relation of ammonium toxicity to hepatic coma is briefly discussed

We wish to thank the Medical Research Council for a maintenance grant to one of us (E A. P), Dr Laurens P White for help in evolving the method of estimating blood-ammonium, and Miss Marjorie Cole, B SC, for biochemical assistance

ACHALASIA OF THE CARDIA IN ADOLESCENTS PRESENTING WITH RESPIRATORY SYMPTOMS

DEWI DAVIES
M.D Lond, M.R C.P
SENIOR MEDICAL REGISTRAR

JOHN C ROBERTS
M D Lond, M R C P
PHYSICIAN

HAREFIELD HOSPITAL, MIDDLESEX

USUALLY the diagnosis of achalasia of the cardia is made in adults presenting with difficulty in swallowing and regurgitation of food On questioning, they often admit to some difficulty in swallowing for many years, but the early symptoms are so slight and the deterioration so grad[illegible] that they do not seek medical advice for a lo[illegible] Even these cases, presenting in adult life, [illegible]lation about the time of development of the disorder and raise the possibility that it may b congenital

It is not uncommon, however, for the discovery to b made in childhood Thus Olsen et al (1953), reviewin 601 cases, found 17 to be under the age of 16 at the tim of diagnosis, the youngest being 2 years old. In 24 o them the symptoms had developed before the age of 10 Such children grow up with a disordered swallowin mechanism and may not realise how much they depar from the normal They often acquire habits to overcome their difficulty, and may take gulps of fluid, breathe deeply, or crouch forwards while eating

Andersen et al (1953) found pulmonary complication in 63 of their 601 cases In most of these the compli cations were preceded by dysphagia But it has bee recognised for a long time that achalasia may be mistake for respiratory disease, particularly in children (Moersc 1929) Belcher (1949) collected 34 cases with pulmonar complications from his own experience and from th literature In 6 of these the œsophageal disturbance wa virtually silent, not arousing complaint by the patient and in some others dysphagia was slight

The purpose of the present paper is to emphasise aga that patients with achalasia can present with respirator disease from spill over of œsophageal contents This i particularly so in children and adolescents, and con siderable vigilance may be required to arrive at the caus of the trouble

Illustrative Case-reports

Case 1 —At the age of 13 this boy coughed up blood o two occasions, and investigation revealed no cause for th At the age of 14, and in the summer, he developed a dr cough During the following winter he began to produc purulent sputum, but this again cleared with the advent o summer He was then admitted to hospital, at the age of 1 as a possible case of bronchiectasis While being investigate for this, he was observed to take a long time over his foo and to swallow water after each mouthful A history o indigestion was obtained, and it appeared that for abou two years he had had some difficulty in getting food dow He had developed the habit of gulping fluids with h meals

On clinical examination no gross abnormality was foun Radiography of nasal sinuses and chest was normal, and were bilateral bronchograms A barium swallow show achalasia of the cardia with œsophageal dilatation and pylor spasm

After dilatation of the cardia with a Negus hydrostati bag, the cough cleared and swallowing improved At the e of two years a barium swallow passes down the œsophagu into the stomach without any suggestion of obstruction, an the lumen has returned to normal No further treatment h been required

Case 2 —A boy of 14 lived in a caravan on a fa ground Neither he nor his parents could give a prec history

At about the age of 10 he swallowed some petrol, he h some cough and vomiting afterwards, but his symptoms we not severe and soon cleared At about the age of 12 he had cough with vomiting for three or four days and spent a night in hospital At the age of 13, and about a year bef admission, he had pneumonia He had fever, right sided ch pain, cough, and vomiting Cough with mucoid sput persisted after this, and his breathing became rather no Three weeks before admission he became ill again with fev right-sided chest pain, cough, and frothy sputum He w admitted to hospital with a provisional diagnosis of pneumo complicating bronchiectasis

On admission his temperature was 103°F and his breath was rapid The mediastinum was displaced a little to t right, and there were signs of consolidation at the right ba He had marked polymorph leucocytosis, and his mucopuru sputum gave a growth of *Hæmophilus influenzæ*

The response to penicillin was rapid During recovery vomited while doing postural tipping Radiography of chest showed a little persistent consolidation at the right b with widening of the upper mediastinal shadow A bar swallow confirmed the presence of considerable dilatatio the œsophagus and constriction at the cardia. After a short period the sphincter relaxed and allowed a fair flow of barium into the stomach. The boy then admitted that food tended to stick at the lower end of his sternum, and that he could help it down by breathing deeply Bronchography showed no abnormality

His symptoms were relieved by Heller's operation. The appearances at operation and during barium swallow confirmed the diagnosis of achalasia. When seen at Henley Regatta eighteen months later, he was symptomless.

Case 3—In 1944 at the age of 18 this patient spent three months in a military hospital with severe cough, copious bloodstained sputum retrosternal pain, and vomiting after food. Bronchitis was diagnosed His symptoms recurred and he was invalided from the Army in 1945 with a diagnosis of bronchiectasis. He spent several periods in hospital after this.

In 1947 he still had a troublesome cough and produced 3 or 4 oz. of foul sputum daily He complained of some vomiting particularly during the bouts of coughing and he also had some difficulty *in swallowing solid food* In October 1947 his bronchiectatic left lower lobe was removed. His cough and sputum then improved, but dysphagia persisted A diagnosis of achalasia of the cardia was made in December 1947 Dilatation with mercury bougies only produced a little relief so Heller's operation was eventually done Four years later he had a slight cough with a little purulent sputum. A little dysphagia persisted and a barium swallow still showed some hold up at the cardia.

This patient's chest X rays showed widening of the upper mediastinum, and in one penetrating film the dilated œsophagus showed clearly through the heart shadow

Discussion

A detailed history usually gives the best clue to the diagnosis but specific questioning about swallowing may be necessary Considerable help is often given by radiography of the chest The changes however are roughly proportioned to the degree of œsophageal dilatation and in case 1 the straight film provided no clue With moderate dilatation the mediastinal shadow is widened from the right border of the heart upwards to the root of the neck The right cardiophrenic angle may also be occluded In the lateral view the trachea is displaced forwards and the mixture of food and fluid in the œsophagus may show up as a mottled density anterior to the vertebral column This was well shown in case 2 With grosser degrees of dilatation the œsophagus encroaches more on the lung field and the diagnosis becomes increasingly obvious Sometimes air in the upper œsophagus may form an area of translucency in the mediastinum in addition to that of the trachea

The spill-over of œsophageal contents into the bronchial tree may produce a wide variety of respiratory disorders, ranging from an irritant cough and a tickle in the throat to pneumonitis abscess, bronchial occlusion bronchiectasis lung fibrosis and lipoid pneumonia Lung shadows with acid fast saprophytes in the sputum may also be mistaken for tuberculosis unless the cultural characteristics and the pathogenicity of the organisms are studied (Breakey et al 1951) These cases show the insidious character of the early symptoms of achalasia which may be accepted by the patient as normal for him The respiratory complication may overshadow the primary pathological process.

We wish to acknowledge our indebtedness to Mr T Holmes Sellors, who operated on cases 2 and 3; and Mr Vernon Thompson, who operated on case 1

PLASTIC APPLIANCES MOULDED DIRECT TO PATIENT

J B BRENNAN
M B Glasg
REGISTRAR IN PHYSICAL MEDICINE WHITTINGTON HOSPITAL, LONDON

PLASTIC orthopædic appliances are, generally speaking lighter cheaper more comfortable and less difficult to make than those of metal and leather and for most purposes they are just as strong and durable

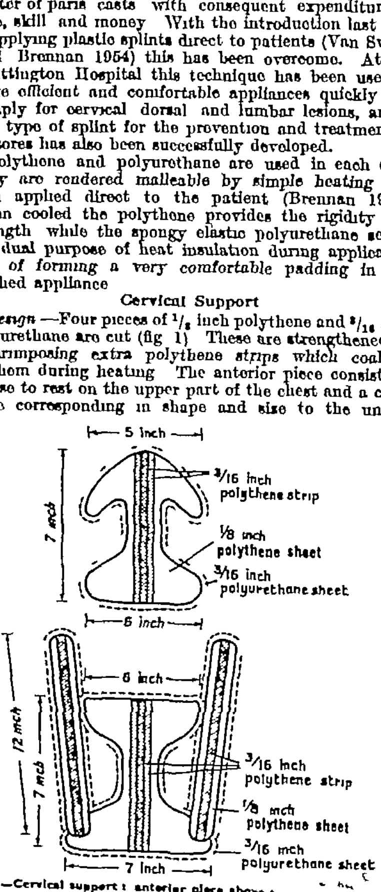
Much research has been required in the development of these fascinating plastics In this country the plastic research unit of the Royal National Orthopædic Hospital has played a leading rôle in this respect (Scales 1950, 1951)

The major impediment to their general use was the necessity of shaping the appliances to previously prepared plaster of paris casts with consequent expenditure of time, skill and money With the introduction last year of applying plastic splints direct to patients (Van Swaay 1954 Brennan 1954) this has been overcome. At the Whittington Hospital this technique has been used to make efficient and comfortable appliances quickly and cheaply for cervical dorsal and lumbar lesions, and a new type of splint for the prevention and treatment of bedsores has also been successfully developed.

Polythene and polyurethane are used in each case They are rendered malleable by simple heating and then applied direct to the patient (Brennan 1954) When cooled the polythene provides the rigidity and strength while the spongy elastic polyurethane serves the dual purpose of heat insulation during application and of forming a very comfortable padding in the finished appliance

Cervical Support

Design—Four pieces of $^1/_8$ inch polythene and $^3/_{16}$ inch polyurethane are cut (fig 1) These are strengthened by superimposing extra polythene strips which coalesce to them during heating The anterior piece consists of a base to rest on the upper part of the chest and a chin piece corresponding in shape and size to the under



5 inch
7 inch
3/16 inch polythene strip
1/8 inch polythene sheet
3/16 inch polyurethane sheet
6 inch

12 inch
7 inch
3/16 inch polythene strip
1/8 inch polythene sheet
3/16 inch polyurethane sheet
7 inch

Fig 1—Cervical support: anterior piece above; shoulder-straps below

The plastics arranged as shown above are in the oven (this applies also to figs. 3 6 ments are average.

surface of the chin and rami of the mandible, the two being joined by a strong narrow strip for the neck The posterior piece is cut in a similar way, the upper end being shaped to fit round and under the occiput The shoulder straps are cut to the required length, and during heating their posterior ends are coalesced to the base of the posterior piece

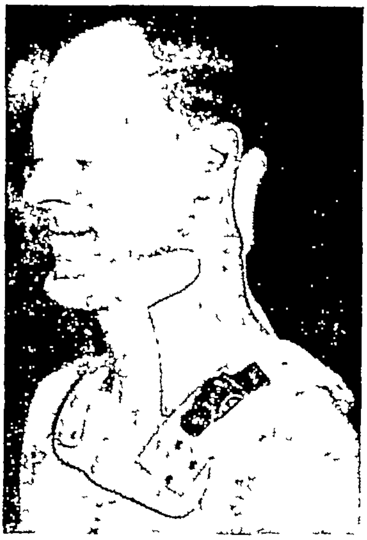

Fig 2—Cervical support in position on patient.

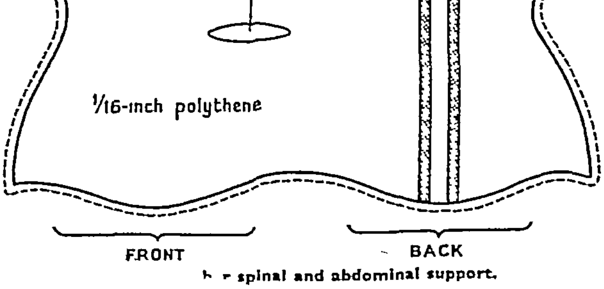
Application —The patient sits with his head and neck in the correct position The heat softened anterior piece is removed from the oven and placed in position Two turns of a crêpe bandage are made under the chin and over the vertex to fix the anterior piece temporarily The posterior piece and its attached shoulder straps are then placed in position, and the bandage is taken round the neck to include both anterior and posterior pieces Bandaging is continued until all the parts are gently moulded to the skin It is not necessary to bandage round the chest to mould the bases and shoulder straps, once the upper parts are fixed in position, these can be moulded with the fingers Within 15 minutes the plastics cool sufficiently to be removable without losing their shape Before this is done, however, the overlap of the two shoulder-straps on the base of the anterior piece should be marked in ink so that they can later be riveted to it in the correct place

Finishing —The shoulder straps are fixed to the anterior piece with bifurcated steel rivets or by welding with an electric soldering-iron The left shoulder strap is next divided near the front, and the separated pieces are joined again with a 1 inch buckle and a leather strap The appliance is then ready to wear It is put on by springing apart the cut polythene shoulder strap and slipped on sideways from right to left into position The leather strap and buckle are fastened, and the appliance is in place (fig 2) The patient requires no assistance to put it on or remove it

Comments —This appliance allows a small amount of cervical movement, but it is within the painless range in most cases, and flexion, usually the most undesirable movement, is entirely prevented The $^3/_{16}$ inch polyurethane padding allows the patient to chew and swallow comfortably Almost any degree of immobility can be obtained by modification of this design For example, a semicircular strip of the plastics may be moulded round the right side of the neck and riveted to the anterior and posterior pieces Again, the chin-piece may be extended backwards on both sides to overlap the occipital part of the posterior piece and be riveted to it The appliance, being moulded close to the skin, is inconspicuous and causes little self-consciousness The finished appliance weighs 7–12 oz, and the materials cost from 6s to 11s With a little practice these cervical supports can be made by a physiotherapist or a technician in less than an hour without assistance



spinal and abdominal support.

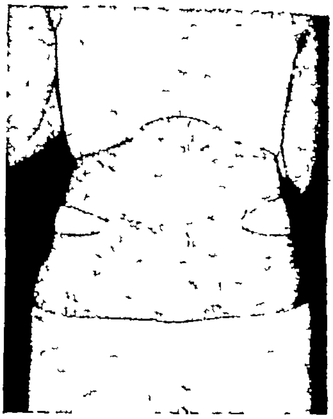


Fig 4—Lumbar spinal and abdominal support of $^1/_{16}$ inch polythene with extra polythene strip forming pelvic hoop. Weight 12 oz.

Spinal Support

Design —The plastics are cut in one piece (fig 3) from $^1/_{16}$ inch or $^1/_8$-inch polythene and $^3/_{16}$ inch polyurethane and strengthened with strips of polythene where required With experience full length spinal braces can be produced A cervical support, as described above, can be added to the brace if required To assist moulding, an elliptical window is cut out above the iliac crest on the closed side of the support (fig 4), if this is not done, wrinkles will develop at the waist

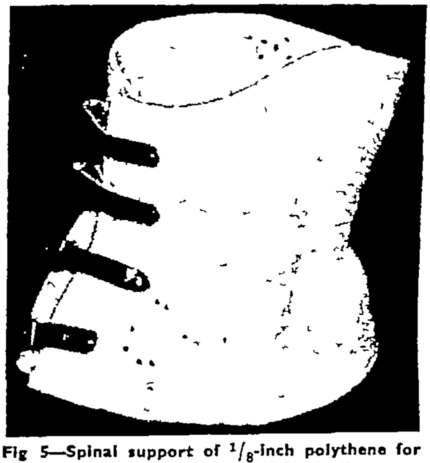

Fig 5—Spinal support of $^1/_8$-inch polythene for patient with chronic back pain due to degeneration of intervertebral discs L1–L4 Upper border of jacket is just below breasts anteriorly and inferior angles of scapulæ posteriorly Weight 1 lb 12 oz.

Application —The patient stands in optimal posture with his arms abducted to 90° If the abdomen is prominent it should be bound firmly before the materials are applied The sheet of plastics is then wrapped round and held in front by an assistant, while the operator ensures that it is correctly positioned It is then fixed in place with a 3 inch crêpe bandage applied with just enough tension to mould it correctly The patient can then lower his arms The mould is taken off after 15–20 minutes and set aside to cool and harden further After 10 minutes it is reapplied to the patient and the fitting is checked An excess or overlap is marked in ink for future removal

Finishing —A row of 1 inch straps and buckles is provided along the open end (fig 5)

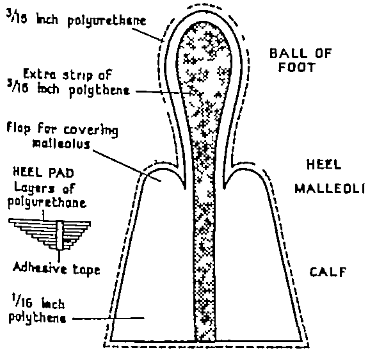
Comments —The weight of these appliances will vary widely with their size, the thickness of the polythene and the number of strengthening strips used. A $^1/_{16}$ inch polythene corset for lumbar and abdominal supp reighs about 10 oz, and a full length $^1/_8$ inch polythene pinal brace for dorsal-spine lesions about $2^1/_2$ lb or a ittle more. Cost will therefore vary roughly from 10s o 35s

Bedsore Splints

The great difficulty in treating bedsores is to keep pressure off the ulcerated areas and so to allow local treatment to take effect I believe that supports made of polythene and polyurethane will be of immense value in treating bedsores Two examples are given of splints designed to provide complete and continued relief from pressure

Heel-sore Splint

Design—Polythene $^1/_{16}$ inch and polyurethane $^3/_{16}$ inch are used strengthened with a strip of $^3/_{16}$ inch polythene (fig 6) While the plastics are being heated a pad of polyurethane about $2^1/_2$ inches thick is taped to the heel and tapered over the distal part of the Achilles tendon (fig 6) When the splint is being moulded this pad, being t and elastic is compressed evenly and gives a smooth anded mould The same pad can be used for each case.



$^3/_{16}$ inch polyurethane
BALL OF FOOT
Extra strip of $^3/_{16}$ inch polythene
Flap for covering malleolus
HEEL
HEEL PAD Layers of polyurethane
MALLEOLI
Adhesive tape
CALF
$^1/_{16}$ inch polythene

Fig 6—Heel-sore splint

Application—The plastics are applied in position from e calf to beyond the toes and moulded by bandaging und the limb and over the pad The splint is removed ter 10 minutes and set aside to cool to room tempera re The pad is taken off the sore

Finishing—The splint is finished with leather straps d buckles. When it is applied to the patient it is seen at, the splint having been moulded over the pad an r gap is left below the heel so that no pressure whatso er acts on the sore The heel cannot fall down into the p because the foot is kept dorsiflexed by the diagonal raps (fig 7)

Comments—With this design the pressure previously pplied to the heel is distributed over the soft bulk of e calf muscles By bringing the plastics above the es during moulding the bed-clothes are prevented from earing on them Finally there is room left for a dressing ough generally the sore will heal spontaneously when lieved of pressure When the splint is discarded it is sually possible to find another patient of similar measure ents for whom it can be used

acral-sore Jacket

Design—Whereas the heel sore splint is easy to ake and when applied requires little attention, it is ifficult to devise a sacral-sore jacket with similar virtues lowever the appliance here described has been found dequate provided the nurses make sure that it stays in osition As with the heel splint the jacket is designed o keep pressure off the sore and to redistribute it over wide area The materials are cut as in fig 8 from $^3/_{16}$ inch olythene and $^1/_2$-1 inch polyurethane for the posterior iece and $^1/_{16}$ inch polythene and $^3/_{16}$ inch polyurethane for the anterior piece A 2 inch overlap of polyurethane is provided below the lower border of the posterior piece and later turned out and pressed on to the outer surface of the heat-softened polythene it then adheres firmly to it thus forming a well padded lower border

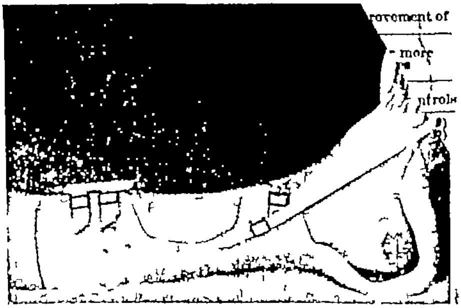


Fig 7—Heel-sore splint in position on patient. Malleolar flaps have not been provided in the prototype splint illustrated here.

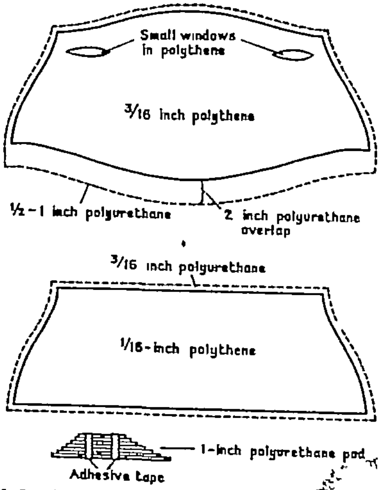
Application—Since most patients requiring a sacral sore jacket cannot stand the patient is kept in bed and the jacket is applied in two pieces—anterior and posterior A 1 inch pad of polyurethane is built up from $^3/_{16}$ inch pieces (fig 8) its area being rather larger than that of the sore This pad is laid on the sore, and the heat softened posterior piece is laid over it. The plastics are manually moulded to the area until cooled and hardened this takes about 10 minutes They are then removed the patient is turned over to lie supine, and the anterior piece is laid on and moulded

Finishing—The anterior and posterior pieces are riveted together where their lateral borders overlap A strip 1 inch wide is next cut out down the middle of the anterior piece and four straps and buckles are fitted Ventilation holes are next punched out, and the jacket is ready to wear If the patient is incontinent, oiled silk



Small windows in polythene

Discussion

Polythene is an almost ideal material for splints and appliances it is inert, radiolucent, and extraordinarily durable , it moulds easily and accurately , and the splint or appliance has a resiliency which enables it to be sprung apart without breaking as the patient puts it on Almost complete rigidity can, however, be obtained by superimposing strengthening strips which coalesce with the body of the appliance during heating These strips *are placed in such a way that the limb or trunk* is prevented from moving in a direction which is harmful, while allowing some movement in other directions This is often of great physiological value, particularly in limb splints (Brennan 1954)

The key to the technique of direct application to the patient is the polyurethane This plastic both insulates the patient from the heat of the polythene during application and forms a most comfortable padding in the finished support It does not have to be glued to the polythene, because it adheres firmly to it during heating (Brennan 1954) Like polythene, it is radiolucent and inert The ratio of continuous to discontinuous air cells is one of the determining factors in the unique padding properties of polyurethane The plastic is laid first on the limb, and, during application, the wet plaster-of-paris partially penetrates its spongy substance so that when dried the polyurethane is firmly adherent to the plaster This is of particular value in removable plasters Another application for this plastic has been introduced by Dr G H Dobney, who advises the use of simple pads of 1-inch polyurethane in place of orthopædic felt or sorbo rubber for the treatment of selected cases of bedsores Being porous to air this plastic has a distinct advantage over the other materials

Polythene costs 13*s* 2½*d* a lb , and polyurethane 13*s* 10*d* a lb —i e , 13*s* 6*d* per lb of the finished support Since very little material is wasted, the cost of the finished appliance is in direct proportion to its weight, plus an additional few pence for straps and buckles These appliances are thus most economical, particularly because they can often be used again when discarded, by heating till flat and reapplying to another patient

I am indebted to Dr G H Dobney for his kindness in reviewing this paper and for permission to publish My thanks are due to Miss E Mason, of the photographic department of St James's Hospital, Balham , Mr A R Kourik, surgical technician, of the Whittington Hospital , and Mr J H Salmon and the staff of the engineering department of Highgate *Hospital for their help*

U K patent application no 16668/54 has been assigned to the National Research Development Corporation by Dr J T Scales A patent has been applied for by M V Esta Voorschoten Holland covering the use of polyurethane foam and 'Perspex' in combination *Polythene* is made as 'Vitrathene' by Messrs Stanley Smith & Co , Isleworth Middlesex *Polyurethane* is made as Moltopren ' by Kay Brothers Ltd Hurst St Reddish near Manchester *Tubular steel rivets buckles &c* are obtainable from Darwen & Co Ltd. Featherstone Street London E C 1 *Plastic glue* ('Evo Stick 528) can be had from Evode Ltd , Stafford, England

VITAMIN E IN THE TREATMENT OF PRIMARY DYSMENORRHŒA

E Blanche Butler
M B Wales, M R C O G
REGISTRAR, DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY
CARDIFF ROYAL INFIRMARY

Edith McKnight
M B , B Sc Glasg , D P H.
STUDENT HEALTH OFFICER, UNIVERSITY OF WALES

WITHIN recent years much has been published on the therapeutic value and physiological effects of vitamin E (α-tocopherol)

Adamstone (1931) first reported that the tocopherols were associated with the development of the vascular system in chick embryos Shute (1942) found that senile vulvovaginitis improved clinically under treatment with vitamin E and biopsy showed that this was due either to the reopening of capillaries or to the proliferation of new blood vessels. As there was a time lag of four weeks, he suggested that the latter explanation was the more likely Favourable results *have also been published of the* use of vitamin E in *Buerger's* disease It was suggested that α tocopherol, by improving the blood supply to the muscles or by promoting a better utilisation of oxygen, relieved the ischæmia which caused intermittent claudication Mason (1942), found that a deficiency of vitamin E caused vascular abnormalities such as stasis, distension, and thrombosis in the vessels of the uterine wall in pregnant rats

We have *found no previous record of the use* of vitamin E in spasmodic dysmenorrhœa This condition occurs chiefly in girls and young women, and in the classical case pain is present just before and at the *onset of the menses* In some cases the pain is so severe that the patient regularly loses a day's work, and in less severe cases working ability may be impaired The cause is uncertain, but one hypothesis is that it is due to muscle ischæmia caused by constriction of the uterine blood-vessels at the onset of the menstrual period If this is correct, relief of pain might be expected from the use of vitamin E, which is reported to relieve vasospasm

Method

Our investigation was made with the cooperation of women students living in the halls of residence of the University of Wales All were between 18 and 21 years of age, some being in their first year of university training, and others in their second or third

At the routine medical examination conducted by the student-health service a careful menstrual history was taken from all the female students, and 100 were chosen who gave a history typical of spasmodic dysmenorrhœa These girls had menstrual periods which were regular and otherwise normal Their general health was good and, so far as could be ascertained, they had no psychological difficulties Vaginal examination to exclude pelvic disorder was not done, because of the age of the students The 100 students were spread over three successive academic years

50 girls were given a course of vitamin E tablets, and the remaining 50 (controls) a similar course of placebo tablets These were provided by the firm which supplied the α tocopherol and of the same size, shape, and colour as the vitamin-E tablets All taking part in the experiment were living under similar conditions as regards study, recreation, and diet

The girls reported to the warden of the hostel ten days before the period was due and were given either vitamin E or the placebo in strict rotation Allocation to the treated and control groups was therefore entirely at random, and bias in assessing the results of the treatment was avoided because we, the assessors, did not know which girls had received the vitamin

The course comprised vitamin E (50 mg t.d.s.) for en days before the menstrual period and for the next our days. This fourteen-day course was repeated for wo menstrual cycles and in some cases for three cycles according to the timing of each girl's menstrual periods during the experiment.

Results

Of the 50 given vitamin E 4 girls reported no pain during menstruation in the first treated period but a recurrence of pain in the second treated period. In 2 of these cases there was improvement again in the third period, whereas in the 2 others pain persisted. In these cases the result in the final treated period under consideration has been accepted.

Results are available at the second month for all 100 girls, but in the third month no results are available for 12 of the treated group and 15 of the controls, because the vacation intervened. The results at the second month are therefore considered first (table I).

Second-month Assessment

Table I is divided into three sections. In section A the symptoms during the menstrual period of the second month are compared with those during the last menstrual period preceding the experiment. In section B the symptoms during the premenstrual phase of the second month are compared with those during the last premenstrual phase which preceded the experiment. In section C the symptoms during both the premenstrual and the menstrual phases of the second month are combined and compared with similarly combined features of the premenstrual and menstrual phases of the month preceding the experiment.

This combined grouping depended on the summation of the Xs in the premenstrual and menstrual periods together. For example cases of "X 2X," indicating discomfort in the premenstrual phase together with slight pain during the menstrual period, were combined with cases of "0 3X" indicating absence of pain in the premenstrual phase but severe pain during the menstrual period. However, of the 19 cases classified in the treated group of section C as "3X" before the experiment began 18 were of the "0, 3X" type.

TABLE II—SECOND MONTH RESULTS

Based on experience in	Percentage showing improvement of			
	One or more stages		Two or more stages	
	Treated	Controls	Treated	Controls
A menstrual phase only	68 (*50*)	18 (*50*)	41 (*49*)	8 (*49*)
B premenstrual phase only	81 (*16*)	30 (*20*)	64 (*14*)	15 (*20*)
C premenstrual and menstrual phases combined	68 (*50*)	22 (*50*)	47 (*49*)	14 (*49*)

Numerals in parentheses show numbers on which the percentages are based—i.e., those who could have improved the required number of stages.

The totals in table I show that whether judged by symptoms in the menstrual phase only or by symptoms in the premenstrual phase only, or by a combination of the two, there was little difference as regards severity of symptoms between the treated and controls before the experiment began.

All the cases tabulated to the left of the zigzag line showed improvement of at least one stage at the end of the second month compared with their staging previous to the experiment. The table is to be read as follows.

In the treated group before the experiment 1 girl had slight discomfort (X) during the menstrual period; at the second month after receiving vitamin E she had no symptoms (improved one stage).

TABLE I—SECOND-MONTH RESULTS

A BASED ON SYMPTOMS DURING MENSTRUAL PHASE ONLY

Pre-treatment category	Treated					Controls					% improved one or more categories		% improved two or more categories	
	2nd-month classification					2nd month classification								
	0	X	2X	3X	Total	0	X	2X	3X	Total	Treated	Controls	Treated	Controls
0														
X	1				1		1			1	100			
2X	5	6	9	1	21	2	2	19	1	24	52	17	24	8
3X	7	8	7	6	28	1	1	3	20	25	79	20	54	8
	13	14	16	7	50	3	4	22	21	50				

B BASED ON SYMPTOMS DURING PREMENSTRUAL PHASE ONLY

Pre-treatment category	0	X	2X	3X	Total	0	X	2X	3X	Total	Treated	Controls	Treated	Controls
0	34				34	30				30				
X	1	1			2						50			
2X	1	2	2		5	1	2	5	1	9	60	33	20	11
3X	2	6	1		9	1	1	1	8	11	100	27	89	18
	38	9	3		50	32	3	6	9	50				

C BASED ON SYMPTOMS DURING PREMENSTRUAL AND MENSTRUAL PHASE COMBINED

Pre-treatment category	0	X	2X	3X	4X	Total	0	X	2X	3X	4X	5X	6X	Total	Treated	Controls	Treated	Controls
0																		
X	1					1		1						1	100			
2X	3	4	7	1	1	16	2		13					15	47	13	20	13
3X	5	3	5	6		19			3	11				14	68	21	42	
4X	1		2	1	2	6			3		5		1	9	67	33	50	33
5X																		
6X	2	1	5		1	9	1		1			1	8	11	100	27	100	18
	12	8	10	8	3	50	3	1	20	11	5	1	9	50				

Sections A and B: 0 free from pain X discomfort; 2X, pain but no disability 3X incapacity requiring rest in bed.
Section C: Summation of Xs in menstrual and premenstrual phases maximum possible pain 6X (see text).

21 girls had slight pain (2X) before the experiment, but at the second month 5 of these were symptom free (improvement of two stages), 6 had only discomfort (improvement of one stage), 9 were unchanged, and 1 was worse (incapacitated)

28 girls were incapacitated during the menstrual period before the trial At the second month 7 of them were symptom free, 8 had only discomfort (two stage improvement), 7 had slight pain but were not incapacitated (one stage improvement), and 6 showed no change

Thus 34 of the 50 treated (68%) showed some improvement compared with only 9 of 50 (18%) of the controls Of a possible 49, 20 (41%) improved two stages (significant improvement) compared with 4 of 49 controls (8%) who could have improved two stages The differences between the treated and controls are statistically significant Variations in the proportions showing improvement in the different severity groups are shown in the last two columns of the table

The tabulations of sections B and C are to be interpreted similarly and the principal results are summarised in table II

Tests of significance were applied to all the differences between the treated and controls, and in each case the difference was most unlikely to have arisen merely by chance

In every comparison the improvement shown by the treated was superior to that shown by the controls, and the last two columns of table I show that, in the treated, improvement was greater where the assessment before the trial was most severe

Third month Results

Before analysing the symptoms reported at the third month it was necessary to consider the effect of losing 12 girls from the treated and 15 from the controls If, for example, the defaulters from the treated had all been severe cases, but the defaulters from the controls only the mild cases, this might have invalidated the final comparison In the event, however, no significant difference was found between the pre trial assessments of the defaulters of the two groups, whether based on premenstrual, menstrual, or combined assessments.

TABLE IV—THIRD MONTH RESULTS

Based on experience in	Percentage showing improvement of			
	One or more stages		Two or more stages	
	Treated	Controls	Treated	Controls
A menstrual phase only	76 (*38*)	29 (*35*)	59 (*37*)	14 (*35*)
B, premenstrual phase only	91 (*11*)	29 (*14*)	82 (*11*)	14 (*10*
C, premenstrual and menstrual phases combined	76 (*38*)	29 (*35*)	62 (*37*)	20 (*3*

Numerals in parentheses show numbers who could have improved to the specified extent

Table III presents the analysis of the third month results and is to be interpreted in the same way as table I. The results are summarised in table IV

Improvement during the menstrual phase was shown by 76% of the treated and only 29% of the controls; 59% of the treated improved two stages as against only 14% of the controls

Only 11 of the treated and only 14 of the control had symptoms during the premenstrual phase before the experiment started 10 of the former (91%) but only 4 of the latter (29%) showed premenstrual improvement after three months' treatment

On assessment during the premenstrual and menstrual phases combined, 76% of the treated as against only 29% of the controls showed improvement 62% of the treated but only 20% of the controls improved two stages

TABLE III—THIRD-MONTH RESULTS

A and B O free from pain X discomfort, 2X pain but no disability 3X incapacity requiring rest in bed
C Summation of Xs in menstrual and premenstrual phases, maximum possible pain 6X (see text)

General Remarks

Vitamin E appeared to have a cumulative effect in most of the successfully treated cases. 20 of the girls who were given vitamin E became entirely free from pain in the premenstrual and menstrual phases This result was obtained in 8 of them in the first month of treatment, but for the remaining 12 the rate of improvement was more gradual—in some cases with relapses in the second month At the end of the course 17 of the treated girls complained only of discomfort during the premenstrual and/or menstrual phases and immediate improvement in the first month had taken place in only 4 of these

At the routine examination a year later some girls who had taken part in the experiment and had received vitamin E tablets said that their pain had recurred It was less severe but had recurred two to six months after treatment These girls asked for a further supply of vitamin E tablets because they had been impressed by the relief given them

Conclusion

The results obtained with vitamin E in the treatment of spasmodic dysmenorrhœa in this controlled investigation appear to be sufficiently encouraging to warrant extended clinical trials

We are indebted to Prof Ralph Picken, the provost of the Welsh National School of Medicine for permission to undertake this test to Dr E Lewis Faning for the statistical analysis and advice; and to Prof A S Duncan for criticism and help in the preparation of the paper We must also thank the wardens of the halls of residence of the University of Wales for their coöperation and Messrs. Roche Products for the vitamin E and placebo tablets

RESIN-IMPREGNATED PLASTERS

Roy H. Maudsley
M B Lpool, F R C S
FORMERLY SENIOR ORTHOPÆDIC REGISTRAR,
ROYAL FREE HOSPITAL, LONDON

Resin mixed with plaster-of paris enables a cast to be applied which is lighter and stronger than the usual one The resin normally used is melamine formaldehyde ('Beetle Resin') which when combined with plaster of paris gives rise to a very hard cast which resists wetting Any delay in the hardening of the resin is avoided by the use of a catalyst such as ammonium chloride which creates the necessary pH for the setting of the resin

At the Royal Free Hospital London resin impregnated plasters have been used for various purposes over the past eighteen months (Maudsley 1954) Records were kept of 100 consecutive plasters of different types the controls were normal plasters of these types The plasters were applied by different members of the staff but the results were sufficiently consistent to draw the following conclusions:

1 A satisfactory resin impregnated plaster-cast requires little more than half the quantity of bandages that a standard plaster requires.

2 The cast is stronger thinner lighter and more durable than the standard plaster It is preferred by the patient who has experienced both types.

3 Very few walking plasters have been cracked or become soft at the heels and the edges have remained firm despite the frequent washing of the adjacent parts

4 Plasters exposed to rain are not impaired and they may be washed if contaminated They are particularly useful in children

5 The economy has been considerable

Until recently the technique depended on dipping normal 'Gypsona' plaster bandages in a freshly prepared solution of resin and catalyst (Morrison 1953) The trouble that this involved was felt to be justified by the increased quality of the cast No serious disadvantages have been encountered a resin plaster of optimum thickness is easy to remove but a thick one may be difficult. In over 300 cases in which such plasters were applied there was only 1 skin reaction this was an exacerbation of psoriasis Should tingling of the hands occur when using resin plaster, this may be stopped by wearing rubber gloves.

We have now had for trial experimental bandages in which the resin and catalyst are incorporated with the plaster during the manufacturing process and which apparently remain stable In a small series of 20 plaster casts the numbers of experimental bandages used were about half the number used in controls with the usual plaster but the two types of resin impregnated casts did not differ in quality While with normal plaster bandages there is an appreciable loss of plaster when the bandages are squeezed after wetting this loss is negligible in the case of the experimental bandages which may be squeezed very firmly after wetting This small plaster loss means that practically the whole plaster content of the bandages is utilised in the construction of the cast mess is reduced and there is little risk of drains being blocked by resin containing plaster-of paris.

It is expected that resin plasters will prove most useful in both fracture clinics and general orthopædic practice.

I am grateful to Messrs. Smith & Nephew Research Hunsdon Hertfordshire for supplies of the experimental bandage

Preliminary Communication

AN APPARENTLY HOMOGENEOUS SUBSTANCE WITH INTRINSIC FACTOR ACTIVITY ASSOCIATED WITH CELL PARTICLES FROM HUMAN STOMACH

The intrinsic factor of Castle is secreted by the mucosa of the fundus of the human stomach into the gastric juice Little however, is known of the form in which intrinsic factor exists within the mucosal cells The following experiments suggest that part of the intrinsic factor activity of human gastric mucosa is associated with cell particles and the particular substance involved has been isolated in an apparently homogeneous state

Each stomach obtained at operation for duodenal ulcer is placed at once in a vessel surrounded by an ice salt water mixture The mucous membrane is removed washed free from surface blood and mucus with isotonic saline at 0–5°C and cut into pieces about 0 5 sq cm area which are extracted with 2% (w/v) NaCl solution in a macerator for 5 minutes The temperature is not allowed to rise above 12°C Debris is removed by centrifugation at 2000 r p m for 20 minutes and the pale red supernatant liquid (A) is stored in the frozen state for up to 2 months until an adequate amount of material has been accumulated

This material is centrifuged in the 'Spinco' ultracentrifuge using the 20 rotor and subjected at maximal speed to approximately 38 000 g for 10 minutes The clear red supernatant (Z) is carefully removed from the precipitate (B) which has three layers the middle one accounting for about 75% of the whole The precipitate (B) is resuspended in ice-cold distilled water stirred intermittently for 10 minutes and recentrifuged for 20 minutes at 2000 r p m The colourless supernatants (C) from this and two further extractions are mixed and

STAGES IN THE PREPARATION OF INTRINSIC FACTOR SUBSTANCE

Stage		% fæcal excretion of radioactivity after 0 5 μg test dose of ^{60}Co vitamin B_{12}	
		^{60}Co-B_{12} without extract	^{60}Co B_{12} with extract
1 Macerated mucous membrane in 2% NaCl	Debris	90	85
	Supernatant A	92	43
2 A, ultracentrifuged	Supernatant Z	86	51
	Precipitate B	86	44
3 B, extracted with water	Precipitate	94	89
	Supernatant C	94	56
4 C, dialysed against water	Flocculent precip	90	94
	Supernatant D	90	58
5 D, concentrated against gum arabic	Flocculent precip	97	94
	Supernatant E	97	65

dialysed at 0–5°C against glass distilled water until free from chloride ions During dialysis a flocculent precipitate develops which is removed by centrifugation and discarded If the supernatant (D), which has intrinsic-factor activity (see table) is now freeze-dried, the resulting very pale yellow powder, dissolved in phosphate buffer of 0 1 M strength at pH 7 9, shows two electrophoretic protein components both on paper and in the Tiselius apparatus Separation of these components may be achieved by concentrating the extract to about one-fifth of its volume by dialysis at 0–5°C against 20% dextran (Benger) or 50% gum-arabic in water A flocculent precipitate develops which may be removed by centrifugation and the pale yellow supernatant (E) is found after equilibration overnight against phosphate buffer of 0 1 M strength and pH 7 9, to contain only one protein component when analysed electrophoretically on paper and in the Tiselius apparatus and ultra centrifugally in the Svedberg ultracentrifuge

Intrinsic-factor activity has been assayed in patients with addisonian pernicious anæmia by measuring the difference of fæcal excretion of radioactivity after an oral dose (0 5 μg) of cobalt 60 labelled vitamin B_{12} given alone and with the extract to be tested The technique has been fully described elsewhere [1] The amount of material used for assay at each stage in the preparation of substance E represents approximately that derived from one-third of a stomach as removed by partial gastrectomy The method of preparation has been repeated in all but its final stage on four occasions and typical assay results for the various steps are set out in the table

Substance E is pale yellow and will promote the absorption of 32% of radioactive B_{12} in a dose of 10 mg Its chemical composition is under investigation and awaits the preparation of several different samples of the material Ultracentrifugal data indicate an approximate molecular weight of 40,000

Microscopic examination of the precipitate B indicates that it consists of a lower layer composed mainly of damaged cells, a middle layer mainly of mitochondria, and an uppermost layer mainly of microsomes The supernatant (Z) contained some microsomes and a few mitochondria engulfed in mucus The method of preparation of substance E would therefore suggest that it is associated in the cell with the nuclei, mitochondria, or microsomes which are precipitated in the ultracentrifuge together with mucoid material It will be observed however that much intrinsic-factor activity remains in the supernatant Z; and it is possible that the activity of precipitate B might be caused not by particle bound intrinsic factor but by adsorption of intrinsic factor from the supernatant on to mucoid material This possibility was tested by re adding the precipitate obtained in stage 3 to the supernatant Z in order to allow further adsorption to take place This, however, did not occur It would seem therefore that intrinsic factor activity may be present in bound form provided that the adsorbing power of the precipitate had not been lost The activity present in supernatant Z awaits further investigation It may be due to a second substance or to activity from disrupted cell particles

The relation of substance E to the intrinsic factor prepared by Latner and his co-workers [2] is obscure Our material is much less active, of higher molecular weight and slightly coloured One possibility is that it may be a precursor of intrinsic factor secreted by the mucosa into the gastric juice

We wish to thank Mr G E Moloney for suggesting the use of, and providing, the material which made this work possible, Mr B Collett for technical assistance, and Dr R E Davies for advice on the microscopical examination of the precipitates

LEG STIRRUPS FOR CYSTOSCOPY

THE best position for cystoscopy was emphasised by Macalpine [3] in 1936 Since then various types of leg supports have been designed, from the triple jointed St Mark's rests to the simple wide arc stirrups of Page [4]

The hip should not be flexed more than 60°, so that the pelvis remains flat on the table The cystoscope can then be introduced in the male without putting undu tension on the suspensory ligament of the penis Th full lithotomy position is not only inconvenient fo cystoscopy but also carries the risk of straining th intervertebral and sacro iliac joints Schleyer Saunders draws attention to this as a possible cause of postoperativ backache in women after gynæcological operations In old people, who comprise a large proportion of urologica patients, this danger is increased by osteo arthritis and decalcification of the bones As Page [4] points out, the buttocks should rest at the end of the table to allow free movement for the surgeon

The leg stirrups illustrated here have been in use in the urological unit in Bristol for the past two years The legs are held in loose canvas slings with no popliteal compression These slings are fixed to the outer sides of the poles and hook on to the inner sides The sling supports the full length of the calf and prevents excessive abduction of the thighs The poles are insulated with rubber to avoid the chance of burns from diathermy earthing

The poles are fixed to the runners of the table by simple thumb screw clamps which do not have to tightened excessively, because the poles retain th position by friction from the weight of the limb, actin on the clamps through a long leverage If the weig

Leg stirrups in position for cystoscopy

of the limb is taken by an assistant, the poles can be readily adjusted into any position to accommodate a patient with a stiff hip or other deformity of the lower limb which may produce a serious problem for the urologist. For the passage of urethral dilators it is often an advantage to have the lower limbs straight this position can be obtained by lowering and adducting both stirrups without having to re towel the patient These poles are easy to manipulate and simple to understand and are not confusing for the most junior nurse, who may be the only available unscrubbed person in the theatre at that moment

Small restrainers are placed on the table end of the poles to prevent complete adduction of the thighs should the anæsthesia happen to be too light

My thanks are due to Mr F Christmas, of the United Bristol Hospitals, for his help in constructing the prototype illustrated here Messrs. C F Thackray Ltd are now manufacturing these stirrups

A PARALLEL BEAM PORTABLE THEATRE-SPOTLIGHT

THE design of portable theatre-spotlights appears in most cases to have fallen between two stools they are neither true spotlights nor do they give a shadowless light The reflector is usually 15–18 in in diameter bulky, and requires refocusing every time the distance from the lamp to the operating field is altered This distance may vary from 3 ft to 8 ft during an operation but is usually from 3 ft. 6 in to 4 ft 6 in When a lamp of the usual design is focused on an object 4 ft. away a movement of as little as 1 ft. in either direction produces a "ring effect" with falling off of axial illumination Since the diameter of the retracted incision is usually no more than 6 in the wound itself may correspond to the dark centre of the ring" while the edges of the incision may be distractingly bright The diameter of 18 in in the orthodox theatre-spotlight is a futile attempt to provide a source of shadowless illumination The reason for this is clear when one compares the relatively small size of the reflector of the orthodox spotlight with that of the very large main overhead theatre light

Thus there is a need for a high-efficiency parallel beam spotlight for use as an accessory lamp to the main overhead theatre light The need for a lamp of similar specification (though not for the same purpose) was met in the motor industry by the Lucas 700 S L R lamp more commonly known as the Lucas flame thrower, recognised so easily on the road at night by its pencil beam of extraordinary brilliance This lamp (fig 1) has a reflector only 7 in in diameter giving a parallel beam of an intensity far greater than that of any other spotlight with which it has been compared The source of light is a 12 V 48 W prefocused bulb shielded so effectively that there is no glare or dazzle unless one is in the line of the beam Research on whether this lamp could be used as a form of theatre lighting was made in the experimental department of Messrs Lucas, and we found that for theatre purposes a slightly converging beam was even more effective This could easily be obtained by bending the bulb flange so as to allow the bulb to advance forwards along the axis of the reflector

Some heat can be felt in the line of the beam but it is not objectionable and can be reduced if necessary to a minimum by using a heat filter

Although the lamp was primarily designed to work from an accumulator we have for convenience, used a transformer as a source of power thus dropping the voltage to that of an accumulator—i e 12 V Since the source of power is optional, this lamp can provide a form of auxiliary lighting in an emergency

The lamp is mounted on a simple sliding tubular column, whose height can be varied, and a ball and socket joint connects the lamp to an upper and wry necked tube allowing a wide range of movement This is facilitated by a small handle riveted to the lamp housing The lamp base is cruciform, with conducting rubber wheels and has a transformer recessed within it (fig 2)

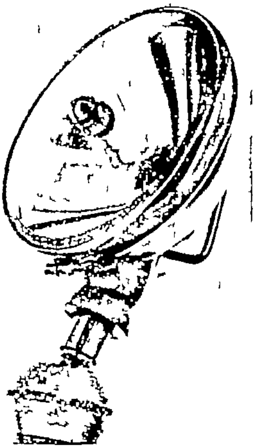

Fig 1

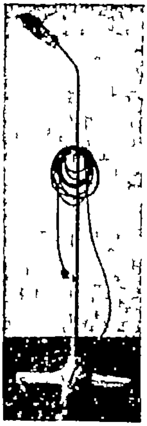

Fig 2.

The lamp has been of great use in gall bladder pelvic, and perineal surgery The beam is so powerful that it can be reflected from retractor blades thus illuminating the depths of the wound This lamp is obviously not the complete answer to the problem of the second theatre light' but it throws a powerful beam which can accurately and easily be directed without the need for refocusing; moreover it is inexpensive

I wish to thank Mr Arnold Gourovitch, F R.C.S.; the staff of the experimental department of Lucas Ltd for help in the design of this lamp Mr F Bradshaw and Mr W Smith for its construction and Mr T Dee clinical photographer for the illustrations.

Reviews of Books

Reflections on Renal Function

James R Robinson, M D, PH D Camb, assistant director of research, department of experimental medicine, Medical Research Council and University of Cambridge Oxford Blackwell Scientific Publications 1954 Pp 163 17s 6d

In his discourse on the working of the kidneys Dr Robinson achieves exactly what he set out to do He presents, in moderate compass, "a clear picture without concealing its incompleteness and lack of finality" Lucidity is the outstanding virtue of this short book which surveys a great deal of ground tersely but unhurriedly These "reflections" make interesting reading because the recalcitrant problems of renal physiology are contemplated from several viewpoints, because controversial findings are described *sine ira et studio*, and because Dr Robinson's thinking is vigorous, and firmly tethered to experimental evidence, straying neither into dogma nor speculation The distribution of emphasis is uneven, which reflects partly the patchiness of present knowledge, partly the author's special interests

The treatise begins with a brief but excellent critical discussion of the concept of clearance and its application to the measurement of glomerular filtration This is followed by a short account of tubular reabsorptive processes Tubular secretion, for the sake of its theoretical aspects, is considered at length *The chapters dealing with the excretion of sodium* and water, the tonicity of the urine, and the allied problem of regulation of the volume of the body fluids, are unconventional and interesting Here—but not in other sections of the book—reasonable familiarity with the basic experimental facts and with the relevant literature is essential to understand the argument By contrast, renal control of acid-base balance is described in more elementary fashion A short, disappointing chapter on the regulation of renal function deals exclusively with limitations of renal function, while much of what is known about the control of renal behaviour is included in the final chapter which appraises the kidneys' unexplained success in conserving the volume of the body fluids

The great value of Dr Robinson's exposition derives from his approach to his subject The "lack of finality" of the picture is made its focal point, and thus becomes a stimulating challenge to further research and further reflection This book will not only serve students reading for an honours degree in physiology, to whom the original lectures were addressed It will help greatly all newcomers to active renal research, and it should be particularly useful to those who have to teach medical students but lack first-hand knowledge of renal physiology and its voluminous literature

Medical History of the Second World War

The Civilian Health and Medical Services Vol II The Colonies, the Medical Services of the Ministry of Pensions, Public Health in Scotland, Public Health in Northern Ireland Editor Sir Arthur MacNalty, K C B, M D, F R C P, F R C S London H.M Stationery Office 1955 Pp 406 45s

This is the 11th volume of the medical history and no less than the 35th of the whole series of official histories of the late war There are 9 more to come in the medical and at least 40 more in the general series Will these war memorials of paper seem to our (problematical) descendants more worthy than the spate of stone and bronze that followed the first world war?

All the sections of this latest volume are of a high quality, but, from the nature of the story, the narratives on Hong-Kong and Malaya are the most exciting—and depressing Sir Selwyn Selwyn-Clarke's Hong-Kong story has a particularly valuable passage on "lessons learnt," and both he and Dr R B MacGregor for Malaya stress the undue effort put into evacuation schemes which failed to be acceptable to the people, and the immense difficulties caused by the lack of any plans or instructions envisaging defeat and the occupation of these Colonies The [illegible] and heroic stories of internment life under [illegible] are full of medical and human interest, though the unanimously low opinion of Japanese intelligence is a wry comment on our own failure to defend Hong-Kong for more than 18 days and Malaya for more than 9 weeks Professor Bernard's account of the splendid resistance of Malta, G C, is a close runner up in interest It is depressing to read of the rise in undulant fever from 1944 when supplies of goats' milk increased and its compulsory pasteurisation was relaxed

Dr A. Sandison's story of the medical side of the work of the Ministry of Pensions is a model of clarity and comprehensiveness, while Scotland has been admirab covered by Sir Andrew Davidson, Dr A K Bowman, a Dr R J Peters, and Northern Ireland by the Minist of Health and Local Government and Dr J Boyd

The Clinical Significance of Disturbances in the Delive of Sweat

Marion B Sulzberger, M D, F A C P department dermatology and syphilology, New York University Po graduate Medical School, Franz Herrmann, M.I skin and cancer unit of University Hospital, New Yo University Springfield Ill Charles C Thom Oxford Blackwell Scientific Publications 1954. P 212 50s

This monograph in the American Lecture Series an expert précis and critical review of what is know about the physiology and pathology of sweating

Part 1 describes methods of investigating insensible a sensible sweating and gives physiological data about regio differences of sweating on the body surface and of the influen of age, sex, and race Part 2 deals with quantitative a qualitative variations, the difference between emotional a thermogenic sweating, and other forms due to toxic su stances, degeneration of nerve tracts, or localised phenomena such as gustatory hyperhidrosis, and axillary hyperhidro on undressing before the doctor Forms of hypohidrosis a anhidrosis include those due to agenesis, defective nerv *mechanisms, degeneration of the glands, or obstruction of t* ductal orifices Dr Sulzberger and Dr Herrmann stret the term "dyshidrosis" to include coloured sweat, bloo *sweat, and offensive sweat, as well as the pompholyx type* eruption to which it was applied by Tilbury Fox in 18 They believe that some instances of pompholyx are, in p at least, related to sweat-duct obstruction, despite rec observations that the ducts veer round and do not p into the vesicles They emphasise that these eruptions a characteristically worse in hot weather and suggest that vicious circle of hyperhidrosis, surface stagnation of swe swelling of keratin, ostial occlusion, sweat retention, and ve culation may account for the clinical features An interesti section attributes diminution of sweating to a decrease electrophysiological potential along the ducts Part 3 discus most adequately the difficult problem of treatment disorders of sweating

Poliomyelitis Vaccines

THE results of last year's trial of poliomyelitis vaccine in the United States, under the auspices of the National Foundation for Infantile Paralysis, have now been announced, and first impressions are very favourable The complexities of the trial make it hard to give a comprehensive figure for the efficacy of the vaccine in protecting against paralytic poliomyelitis, but summaries of the evidence [1] suggest that the advantage it gives to vaccinated over non vaccinated children is about $3^1/_2$ to 1 —a remarkably high figure considering how short was the time for overcoming the many technical difficulties in a trial of this kind. As, even in an epidemic, the number of cases of poliomyelitis which declare themselves by developing paralysis is comparatively small, no trial of a protective vaccine will provide satisfactory data unless it includes a great many people In this trial some 400,000 children received three intramuscular injections of vaccine in the course of five weeks and about 200,000 children were given three "dummy" injections. In addition, about 800,000 children of roughly the same age were observed as uninoculated controls The vaccine was prepared by growing a representative strain of all three serological types of poliomyelitis virus in tissue cultures of monkey kidney cells, and the virus was then inactivated by treatment with formaldehyde at 37°C Healthy tuberculin negative rhesus monkeys provided the kidney tissue, and the final material was rigorously tested to ensure that the infectivity of the virus was destroyed and that no micro-organisms pathogenic for man were present Dr J E SALK and his colleagues in Pittsburgh were largely responsible for the technical development of the vaccine, and most of the virus used in the trial was prepared in the Connaught Laboratories Toronto

The results of the trial are given in a report [2] by Dr THOMAS FRANCIS director of the Poliomyelitis Vaccine Evaluation Centre In a population of 1,829,916 children there were 1013 cases of poliomyelitis during the study period of about eight months In the evaluation, the trial was considered in two parts in some areas vaccinated children were compared with children who had had dummy injections and in other areas vaccinated children were compared with uninoculated controls In the first, called 'placebo control' areas there were 33 paralytic cases among about 200 000 children receiving vaccine, compared with 115 cases among about 200 000 "dummy" controls Similarly, in the 'observed control' areas there were 38 paralytic cases among about 200 000 children receiving vaccine and 330 cases among about 800 000 uninoculated children The advantage of vaccinated to control children in terms of paralytic disease thus appears to be about $3^1/_2$ to 1 in the placebo areas and rather better than 2 to 1 in the observed areas. There was wide variation in the response to different batches of vaccine, and in general the protection against viruses of types 2 and 3 was better than that against type 1 This had been expected from the results of antibody measurements —and unhappily type 1 is at present the cause of most cases of paralytic poliomyelitis The most striking effect of the vaccine was in preventing bulbo spinal disease, in which the estimate of effectiveness of the vaccine for the placebo control areas was 94%, with a lower limit of 81% The effect noted in spinal paralytic poliomyelitis was less striking—60% with a lower limit of 30% In observed control areas these differences were less pronounced but still highly significant It seemed that there was a progressive increase in effectiveness with increase in age, as far as could be judged from the limited data and the narrow age span in this trial In the incidence of non paralytic disease there was no significant difference between the vaccinated and control groups, and when these cases and those considered not to be poliomyelitis are removed, leaving only paralytic cases, effectiveness was estimated at 72% in the placebo control areas and 62% in the observed control areas FRANCIS adds that the estimates would be more secure had there been more cases of poliomyelitis.

A disadvantage of this form of vaccination is that the immunity it confers may not last long Data from the bleedings performed five months after inoculation indicate some persistence of antibodies but a decline in antibody titre particularly in children vaccinated with "poor" batches of vaccine, and SALK is reported to have said that children vaccinated last year should be given a booster inoculation this year [3] He has since suggested [4] a change in the timing of the three injections and we understand that the new procedure will be used for primary vaccinations undertaken this year He now believes that the best plan is to separate the first two injections by two to four weeks, and then to wait for at least seven months before giving the third dose The third injection "should then extend the immunity for an indefinite period, perhaps years, and maybe even a lifetime" [4] This is the vital point, and we hope that what seems at the moment to be an unduly optimistic view will in fact be justified by events But if it is found that contrary to SALK's hopes antibody levels cannot be maintained without a succession of booster doses, then a serious problem will arise Will it be necessary to give injections every year, or every few years, and, if so, for how long should they be given? The report on the trial emphasises the safety of the vaccine but if injections are given regularly for several years to millions of children the risk of allergic reactions to monkey kidney tissue will become increasingly grave We do not yet see any reason to be less anxious on this account than we were six months ago [5] Moreover it is not as if there were no alternative even though passive immunisation with gamma globulin has proved disappointing there is still a very good hope that avirulent strains of virus may be used safely and successfully Immunisation with live avirulent poliomyelitis virus should, like natural infection, give life-long immunity, and there are many who believe that live avirulent variants will provide the ideal method of immunisation and that such vaccines may be available before long In a new World Health Organisation monograph[6] both Sabin and Koprowski favour the ultimate answer of live avirulent poliomyelitis virus in preference to inactivated virus, and they have made considerable advances both in preparing avirulent variants from all three antigenic varieties of virus and in testing some of them in man. There are many difficulties ahead in this field, but there is no reason to believe that they cannot be overcome in the next few years The advantages of both forms of vaccination might perhaps be combined by giving live avirulent virus under the temporary protection of immunity conferred by inactive vaccine

[5] *Lancet* 1954 ii, 851

Naturally enough, the ring of news from America has convinced many people in this country that we should use the vaccine in large quantities as soon as possible But, even if adequate supplies were ready at once, we should be very reluctant to see them used until the present evidence has been fortified, especially in the matter of sensitisation The Medical Research Council are making plans to try a limited amount of vaccine this year and to study the response to it. It seems to us far wiser to go thus warily rather than embark on a large immunisation campaign with a vaccine whose repeated use may prove harmful, whatever its immediate potency As Sabin has observed,[6] we should not judge that the work is nearly finished it is only just begun

Treatment of Angina Pectoris

The usual cause of angina pectoris is atherosclerosis of the coronary arteries, although aortic valvular disease or anæmia may be contributing factors No known treatment will modify the underlying pathological condition, but much can be done to relieve symptoms Most cardiologists agree that patients with angina of recent and sudden onset should be treated as though they had had a coronary thrombosis and a pending myocardial infarct The patient should be kept in bed, except for his toilet, for four to six weeks, he should eat a reducing diet if he is overweight (and frequent small light meals if he is not), and he should be given heparin for forty eight to seventy-two hours, followed by ethyl biscoumacetate ('Tromexan') or phenylindanedione ('Dindevan') By these means arterial occlusion may be prevented, and the return of pain when the patient gets up and finally resumes his normal activity may be averted When the angina is of longer standing, the main points in treatment are weight reduction, light meals (with a rest after them), avoidance of exertion (especially on cold windy days), sedation, and a warm bedroom If pain comes on, glyceryl trinitrate (gr $^1/_{200}$–$^1/_{100}$), dissolved under the tongue after chewing the tablet, will usually relieve it, and many patients find that a tablet taken before embarking on some unavoidable exertion prevents the onset of pain But this treatment does not stop the progress of the disease, and electrocardiographic studies have shown repeatedly that the changes in the S–T segment and the T-wave associated with ischæmia of the myocardium may persist or become more evident despite the relief of the pain with glyceryl trinitrate Of the other vasodilators the capsule of amyl nitrite is usually less acceptable to the patient because of the flushing and the pounding headache it induces After a short popularity khellin has not proved to have any great advantage, and more recently a longer-acting vasodilator, pentaerythritol tetranitrate, has been introduced This is given regularly throughout the day and reduces the frequency or severity of attacks in about a quarter or a third of patients[1]

In about 5% of patients these measures fail to control a pain which strikes so frequently or on so slight a provocation as to prove crippling, and it is very hard to know how to help these people Various operations have been devised to improve the blood supply to the myocardium or to cut the pain bearing nerve-fibres from the heart[2] But most physicians are reluctant to recommend such operations in patients with cardiovascular disease, particularly when the benefits are uncertain They prefer something less hazardous and more readily controlled For many years Blumgart and his associates in Boston have advocated measures which, by lowering the metabolic needs of the body, reduce the demands made on the heart At first they carried out total thyroidectomy,[3] but the advent of antithyroid drugs removed the need for an operation, and lately suppression of the thyroid gland with radioactive iodine has proved an even more acceptable treatment Their practice is to give three doses of 10 millicuries of radioactive iodine at weekly intervals, or a single dose of 20 millicuries Thereafter, at intervals of one to two months, further single doses are given until hypothyroidism is evident, as judged by the patient's appearance, the blood cholesterol level, and the metabolic rate Other workers prefer in the first place to make the patient hypothyroid with an antithyroid drug, such as thiouracil or carbimazole ('Neomercazole'), and then, when the response to a lowered metabolism has been assessed and shown to ease symptoms, they proceed to suppress the thyroid gland permanently with radioactive iodine This seems a more logical course and, moreover, it reduces the dose of radio iodine required to abolish thyroid action Symptoms improve as hypothyroidism develops, and benefit is usually apparent in from one to six months after the start of treatment When hypothyroidism is established and the angina partially or totally relieved, sufficient thyroid extract or *l* thyroxine is given to maintain maximum relief from heart-disease and minimum discomfort from myxœdema this is usually achieved at a basal metabolic rate of –20% to –25%. Blumgart and his associates have now reported the results of this treatment in 720 patients with angina unresponsive to other forms of medical treatment[4] About three quarters have had very satisfactory responses, with a considerable decrease in the severity or frequency of the pain, and in some instances sufficient improvement to enable them to return to work The same therapeutic plan has been used successfully in patients with intractable congestive cardiac failure, and much the same proportion of patients have improved. Although the hypercholesterolæmia associated with hypothyroidism might be thought on theoretical grounds to involve a risk of further atheroma in the coronary arteries, there is as yet no evidence of this in patients receiving small doses of thyroid hormone.[5]

Annotations

THE PRICE OF THE LANCET

WE have to announce, with regret, an increase in the price of THE LANCET. Almost all the costs of production have risen steeply in recent years and we are faced with further rises in the immediate future. To meet these the annual subscription (at home and abroad) will be raised to £3 3s, and the price of single copies to 1s 6d from July 1. Any reader renewing his subscription after that date will be asked to pay £3 3s except that the charge will be reduced to £1 11s 6d for medical students, for doctors within a year of qualification and for those undertaking National Service in H.M. Forces. The rates for the air mail edition will be £1 1s higher than at present.

When we last raised our subscription—in May 1920—we said that we should be delighted when circumstances permit us to return to former prices. The experience of the past thirty five years has taken the edge off such optimism; but we remain sanguine enough to hope that with additional help from our readers we shall presently be able to give additional value to our journal.

MEDICAL EXAMINATIONS FOR SEAFARERS

A MARITIME convention of the International Labour Organisation, requiring everybody employed on sea going vessels to have medical examinations before being signed on and periodically thereafter will come into force this August. It applies to every sea going vessel whether publicly or privately owned which is engaged in the transport of cargo or passengers for the purpose of trade but not to vessels of less than 200 tons gross register tonnage to wooden vessels of primitive build such as dhows and junks to fishing vessels, or to estuarial craft.

The convention was adopted by the Maritime Session of the International Labour Conference at Seattle in 1946 but was only to come into force when ratified by at least seven of the world's principal maritime countries at least four of which must have a million tons of shipping each. These conditions are said to have been fulfilled with the ratification of the convention by the following countries: Argentina Belgium Bulgaria Canada France Italy Norway, Poland Portugal and Uruguay. According to *Lloyd's Register* (1954) these countries between them had a total of just over 18 million tons out of a world total of 97 million tons in 1953 but they could only just fulfil the condition that at least four of the signatories should have a million tons of shipping each: in 1953 France had nearly 4 million Italy nearly 4 million, Norway nearly 7 million, and Canada nearly 2 million of which about half was used on the Great Lakes. Bulgaria one of the signatories of the convention does not appear in *Lloyd's Register* at all. On the other hand the countries which have not signed include Great Britain and Northern Ireland (nearly 19 million) and the United States (27½ million counting 2½ million on the Great Lakes).

For Britain and the U.S.A. to guarantee that *every* seaman in their great merchant shipping fleets will be examined before being signed on would of course be a more serious undertaking than for nations with smaller shipping interests and there might be even greater difficulty in arranging for the subsequent periodic examinations, details of which are not yet known. Obviously, too, the quality of such examinations and the application of their results in each individual case are important. Whether a man shall continue to work or not cannot be decided properly by following some schedule of signs and symptoms but only by knowing a good deal about the man and the tasks he has to perform. Admittedly this is a counsel of perfection, but it would be particularly hard to follow in the peculiar circumstances of the shipping world where periodic medical examination might be feared by the men because it might deprive them of their job and by the employers because it might deprive them of a useful pair of hands. Behind these practical details lies the need to determine the age long divergence of view as to the nature of the Merchant Navy—as to whether it is a service or an industry. Obviously, certain things (like routine medical examinations) can be *required* of a service more readily than of an *industry*.

These may be some of the reasons why the United Kingdom has not as yet felt able to sign the I.L.O. convention. This is not to say that our Government do not approve the principle: indeed, much that the new convention demands is already being done here extremely well. But it would be hard to give a positive assurance that in our vast shipping industry every single man that ever goes to sea on a vessel of 200 tons register or over will for certain receive a medical examination before signing on and periodically thereafter. Perhaps therefore, the chief value of the convention at this stage is as an instrument of international health education: it is another move in what we some years ago described[1] as the "long and arduous campaign for a healthy Merchant Navy" which has "followed the pattern familiar on land, with its battle of environment, battle of personal hygiene, and battle of medical services."

FLUOROHYDROCORTISONE

HALOGENATION of corticosteroids by attaching bromine chlorine or fluorine to the C9 atom in the steroid ring has produced some interesting compounds which, like stilbœstrol in another field are more potent than the naturally occurring hormone.[2] Fluorohydrocortisone is more active than the other halogenated derivatives of hydrocortisone (compound F)[3] and qualitatively its physiological action is similar to that of hydrocortisone. In very small doses it maintains life in adrenalectomised animals, enhances the deposition of liver glycogen and produces thymic involution eosinopenia retention of sodium and increased urinary excretion of potassium.[3-6] The action of fluorohydrocortisone in man has been studied by Bartter[3] and by Thorn and his colleagues.[7-8] Of particular importance is its effect on sodium metabolism. Given by mouth 0.5 mg of fluorohydrocortisone produced in a patient with Addison's disease the same amount of sodium retention as did 2 mg of deoxycortone acetate given by intramuscular injection and the effect of 200 µg of fluorohydrocortisone and of 200 µg of aldosterone was almost identical although the former had a rather longer action. Because it is cheaper than aldosterone and can be given by mouth (in contrast to deoxycortone) fluorohydrocortisone is likely to prove an advance in the treatment of Addison's disease. A single daily dose of 5–10 mg may rescue a patient from a severe addisonian crisis, and as little as 0 25 mg daily or on alternate days may maintain electrolyte balance thereafter But it can readily induce excessive sodium retention, hypertension, and œdema, so it must be given with care Although some patients may remain well on fluorohydrocortisone alone, just as some patients did on deoxycortone alone, others do not feel as fit as they might unless cortisone is given too Thorn et al [7] found that a daily supplement of 2 5 mg of cortisone was usually required

Fluorohydrocortisone is also potent as a suppressor of endogenous corticotrophin secretion Doses of 1–10 mg daily have reduced the urinary 17-ketosteroids to normal in adrenogenital virilism secondary to bilateral adrenal hyperplasia A constant watch must be kept for excessive sodium retention, and if there is evidence of this the patient should have a low sodium diet and extra potassium chloride The anti-inflammatory action of 1 mg of fluorohydrocortisone is similar to that of 20 mg of cortisone or hydrocortisone The intense sodium-retaining effect, however, precludes the use of fluorohydrocortisone in this way, except in the topical treatment of skin diseases Here fluorohydrocortisone ointment has been effective, and it is relatively cheap, because a smaller amount of hormone is needed

SKIN LESIONS IN PERIARTERITIS NODOSA

SKIN lesions are found in about 25% of cases of periarteritis nodosa The best-known manifestation is the subcutaneous nodule, though this is found in only 16% of all cases [10] Ketron and Bernstein [11] doubted whether the diagnosis could always be made histologically from the more superficial erythematous or papular eruptions of periarteritis nodosa, because the vessels involved in these changes were too small to show the distinctive lesions of the disease That it may nevertheless be useful to make a biopsy examination of such lesions is shown by the experience of Bureau and Barrière,[12] who describe a fatal case of periarteritis nodosa with various skin lesions including a "new" manifestation—an apparently superficial circumscribed red scaly eruption resembling tinea, which showed clearer histological evidence of periarteritis than the grosser skin lesions elsewhere

Nodules, as Bureau and Barrière point out, are most commonly found along the course of small arteries, particularly on the legs but also on the wrist, forearm, angle of the jaw, forehead, and neck There may be more superficial papular elements, sometimes with central necrosis, reproducing the appearance of some forms of tuberculides Erythematous macules are common, particularly on the limbs, they may become purpuric or lead to a secondary blister with an appearance resembling erythema multiforme Purpura, which is said to be the most common lesion, may be massive Nearly always it is associated with other skin changes—erythema, nodules, or blisters Occasionally there is dull erythematous or cyanotic reticulation of the skin—so called livedo racemosa Telangiectatic plaques have also been seen Necrosis of the skin may develop either in a way resembling familiar forms of gangrene of the extremities or secondary to blisters which break, leading to the formation of sharply outlined ulcers These may be severe and resemble those in the "phagedenic" ulceration [13] which occasionally accompanies ulcerative colitis The mucosæ of the mouth, nose, and rectum may show papular or nodular lesions, transient blisters, necrotic ulcers, or massive infiltration [14] Nasal infiltration with a tuberculoid granuloma was described by Wegener [15] in patients who died and in whom necropsy revealed widespread visceral lesions of this type and in addition the vascular changes of periarteritis nodosa

It is a long clinical jump to Miescher's [16] benign case in which skin infiltration resembling Bazin's disease showed histological changes interpreted as periarteritis nodosa leading into a tuberculoid process Other workers have reported cases in which skin lesions of the clinical and histological type described in the systemic disease have been found in patients who remained otherwise well Perhaps until the significance of the histological lesion of periarteritis nodosa is understood, such cases should not be grouped with those of the major disease It is not yet clear what types of necrotising arteritis are in fact ætiologically identical, even if their pathogenesis and histological appearance seem similar Bohrod [17] sees enough similarity between them to suggest that they do form a group, whereas Zeek [18] continues to discourage the grouping together of all forms of necrotising arteritis, among which she recognises as many as five categories hypersensitivity arteritis, allergic granulomatous arteritis, rheumatic arteritis, temporal arteritis, and classical periarteritis nodosa

Dermatologists are aware of puzzling cases of skin lesions which have in common two main features—first, histological evidence of vascular inflammation and, secondly, a perplexing lack of evidence of any general physical disease Many of the nodular and necrotising lesions formerly diagnosed as tuberculides are now less confidently regarded as manifestations of tuberculosis Some are called "nodular vasculitis," whereas Gougerot's school impart a more ætiological flavour to their diagnosis of "nodular cutaneous allergides" The evidence for an allergic basis for all of these is unconvincing At present no very useful purpose seems to be served by associating them with periarteritis nodosa in the sense of the classica disease of Kussmaul and Maier

LITHIUM SALTS IN MANIC PSYCHOSIS

THE psychiatric treatment of mania may be difficult and unsatisfactory Sedative drugs often have to b pushed to the point of narcosis or confusion, and even then they may be ineffective Certainly convulsion therapy is usually effective, but the result may be very short-lived and is much less satisfactory than in depressive illness Any new treatment which may be harmless and effective will therefore be sure of an early trial, and lithium salts appear to hold out a limited promise Although they have been used since 1949, following some observations in guineapigs, not many people have been interested in them Schou et al [19] have made a careful clinical assessment of their use in the treatment of 38 cases of mania—30 with the classical "pure" syndrome and 8 with some atypical features, such as delusions and hallucinations Using placebos as a control, they found evidence of sedation in 14 cases and a less definite action in 18, while in 6 there was no effect Improvement appeared to be symptomatic, and patients relapsed soon after lithium was withdrawn The margin between therapeutic and toxic doses was not wide, but with doses of 24–48 m eq of lithium a day no serious intoxication was noted

In practice it is unlikely that this treatment will have more than a limited value, either for temporary effective sedation or for repeated treatment of recurrent mania where the length of the manic phase can reasonably be predicted Nevertheless the mechanism of the metal's action is of considerable interest The timing of the changes that have been observed is important here Lithium has to be given for a week or two to produce its effect though bigger doses act more quickly When it is withdrawn or reduced, judging by minor toxic effects there is an interval of only a few days before a change is seen. This suggests that lithium does not act by displacement of other metal radicals in enzyme systems such as is known to be the case with some other elements The question is certainly worth further study

TUBERCULOSIS AND PERSONALITY

EVERY disease has its drawbacks, but most have some advantages, too, which a patient consciously or unconsciously, may choose to exploit Anyone developing pulmonary tuberculosis is almost automatically withdrawn from the hurly burly for a few months and this may be an emotional as well as a physical relief Indeed George Day[1] has suggested that some people succumb to the tubercle bacillus so as to escape from an unbearable situation while others refuse to heal until time produces some beneficial change in the environment to which they must return These are extreme cases but they serve to remind us that a patient when he brings his soma into the sanatorium does not leave his psyche in the hall with his umbrella His personality, in fact is bound to influence his disease quite as much as his disease influences his personality—perhaps on the whole more

Some cases reported by Wittkower Durost, and Laing[2] illustrate this well Of 80 patients with pulmonary tuberculosis, 40 had a favourable course (group A) and 40 an unfavourable course (group B) The groups were well matched as to age, sex and marital and social status, but the average duration of the illness at the time of examination was longer in group B (10·6 years) than in group A (6·4 years) and the average stay in hospital had also been longer (72·7 months for group B compared with 32·2 months for group A) Diagnosis had been early in 20 of group A but only 17 of group B In 5 patients (2 in group A and 3 in group B) the doctor had failed to recognise the illness early but in 14 of group B and 5 of group A delay was due to conscious or unconscious denial of the symptoms This denial may be self-deceiving and cheerful (manic) or defiant and pig headed

Conscious and obstinate refusal was seen in a foreman who said I had a family of young children. I just couldn t see stopping work and in the mother of five children who refused to go into hospital for two years after diagnosis "I said right off I was not going The only way they got me to come was to tell me I was dangerous to the children Unconscious denial was expressed by a young housewife "I caught a cold I spit some blood In our family when we have a little trouble we do not complain When the doctor told me I had tuberculosis I was surprised Tuberculosis! Gee! Me—tuberculosis!

4 of group B and 1 of group A refused major surgical measures the refusals being based on conscious or unconscious fear of mutilation or disfigurement Again 7 of group B and 2 of group A failed to follow the hospital treatment regulations and 17 of group B as compared with 5 of group A interrupted treatment by discharging themselves. Those who took this line were commonly rebellious duty bound and family bound persons Similarly, 10 of group B and 5 of group A failed to follow medical advice after leaving hospital; either they returned prematurely to strenuous sports and pleasures or to heavy work with long hours.

There was no uniform personality type the observers found, among those who failed to do well but an emotional conflict commonly seen among them was between the need to be loved and cared for and the need to express aggression—the usual conflict, in fact of the immature or infantile personality It was expressed in various ways Thus some patients were frankly dependent openly seeking care and protection others concealed this need behind a hostile front, others suppressed their wish for care and sublimated their aggression in an active striving for independence, others repressed their aggression turning it upon themselves as compulsive self driving behaviour On the whole the patients who acknowledged and enjoyed their dependence did well, whereas those who concealed it behind hostility did badly: as the authors put it (thinking in terms of infantile feeding behaviour) suckers' did better than ' biters. Rebelliousness also presaged an unfavourable course unable to form close relationships because of their hostility these patients suffered continuous frustration of their need for care and love Those who had suppressed this need, and sublimated their aggression in constructive and independent activity tended to do well unless their illness had brought their families into want or privation when harassed by guilt and anxiety they were apt to over-exert themselves too soon Patients who had turned their aggression inwards upon themselves were also likely to do badly, perhaps because of an unconscious wish for self punishment

Group A patients on the whole were more mature in personality, suffering less conflict over dependence less concerned about getting attention, and more capable of accepting responsibility Rorschach tests suggested that there were more flexible people in group A and more rigid people—that is, people less capable of adapting to adverse circumstances—in group B 'Flexibility permits the patient to find substitute gratifications for those which had to be abandoned as a result of illness and its treatment, and thus reduces the total amount of his frustration, aggression and resentment, factors that tend to affect the course of treatment in an unfavourable way '—and indeed, the course of life generally The fox who found the grapes were out of reach called them sour—which is usually interpreted as a sign of his envy and jealousy Actually it was a highly mature response as far as he was concerned they *were* sour—that is no longer desirable. He put the thought of them behind him and went off to look for something else to eat A little of this sour grapes philosophy is essential to flexible living

THE BUDGET

ON Tuesday Mr R A Butler said that our problem in this country is how to maintain our material and social progress and also keep in balance with the rest of the world The burden of taxation is far too great, and industry requires a further incentive But the need is for saving rather than spending Because it would encourage personal expenditure, he is not reducing indirect taxation—except for the purchase tax on textiles. On the other hand, some 2 400 000 people will be freed from income-tax by small increases in the allowances before tax is paid; the standard rate goes down by 6*d* in the £, and the lower rates by 3*d* and children s allowances rise from £85 to £100 Many will believe that different concessions would have been socially preferable But the nature of income tax and of its payers is such that, when it is lowered a little only the most conscientious in the ranks of Tuscany can quite forbear to cheer

Prof G W PICKERING has been appointed regius professor of medicine in the University of Oxford.

WE have to record the death on April 10 of Mr ROBERT DAVIES COLLEY C.M.G consulting surgeon to Guy s Hospital A memorial service will be held in the hospital chapel on Wednesday April 27 at 1 45 P.M

LEPROSY IN BRITAIN

W H JOPLING
M R C P, M R C P E, D T M & H

SENIOR REGISTRAR, HOSPITAL FOR TROPICAL DISEASES, LONDON, AND THE JORDAN HOSPITAL, EARLSWOOD, SURREY

THOUGH leprosy is still endemic in many countries of Europe, particularly in the south, it fortunately died out in Britain by the end of the 18th century After the second world war, however, there was an influx of cases from abroad, consisting principally of Anglo Indians (Eurasians) who left India after the granting of Independence in 1947, and also of returned soldiers and the wives they had married while overseas To meet the problem presented by these patients, and to minimise the chances of leprosy becoming again endemic in Britain, the Public Health (Leprosy) Regulations [1] were brought into operation in England and Wales on June 22, 1951, making it compulsory for cases of leprosy to be notified direct to the Chief Medical Officer of the Ministry of Health At the same time the disease became notifiable in Scotland, but the Department of Health there instructed that notifications should go through the local medical officers of health To date 175 cases have been notified in Britain, all having acquired their infection overseas Also in 1951, the Ministry of Health appointed an adviser in leprosy (Dr R G Cochrane) and was instrumental in establishing a special hospital for inpatient treatment—namely, the Jordan Hospital, Earlswood, Surrey, administered by University College Hospital and staffed by the Hospital for Tropical Diseases

THE JORDAN HOSPITAL

The hospital was opened in September, 1951, and can accommodate 18 patients in two single storey buildings, one for men and the other for women Each building contains a series of centrally heated flats consisting of a bed-sitting-room, kitchen, bathroom, and lavatory A few of the flats have two bed-sitting-rooms, the two occupants sharing the other facilities, and a new block is now being built to take 6 more patients and to provide more rooms for clinical and laboratory work Seven nationalities are represented among the present patients Anglo-Indians (10), English (2), Cypriots (2) Maltese (1), Latvian (1), Indian (1), African (1) As they all suffer from lepromatous leprosy, the form of the disease which is most infective and most difficult to cure, full use is made of the hospital's facilities for scientific treatment and for research The hospital does not admit non-infective patients requiring treatment for deformities and other late effects of the disease

Occupational Facilities

Keeping the patients occupied is a major problem A system of payments has had to be introduced to encourage regular work in the hospital grounds, and those who make rugs, woollen goods, baskets, and so on, are helped by the occupational therapist and the matron to sell them once the articles have been sterilised Several of the younger patients take correspondence courses There is a recreational block, with television and table tennis, where plays and concerts are produced, and the outdoor tennis court is very popular in summer

Investigations

Regular visits are paid by the consultant physicians (Sir Neil Hamilton Fairley, Sir George McRobert, and Prof A W Woodruff) and by our ophthalmic surgeon, Mr D P Choyce One of my duties is to carry out a skin biopsy and 8 smears on each patient every two months The fact that these tests are made by one person, and the results interpreted by one pathologist, Dr D S Ridley, helps to ensure the uniformity essential in testing new drugs Hæmatological and biochemical investigations are regularly undertaken to detect adverse side effects on blood, marrow, liver, or kidneys

Treatment

Inability to cultivate the human leprosy bacillus in vitro, or to find a susceptible laboratory animal, has led to treatment with tuberculostatic drugs Since 1941 the sulphones have held pride of place, but they are slow in action and there are risks in their use Lowe's [2] long term assessment of sulphone therapy in Eastern Nigeria is favourable, but he acknowledges that reports from elsewhere are less encouraging At the Jordan Hospital the lepromatous patients have responded poorly to various forms of sulphones Although they have shown definite clinical improvement, especially during the first two or three years, bacteriological improvement has been negligible within that time only after four or five years have the bacilli in the skin shown a significant decline in numbers At present there are 10 patients in the hospital who have had three or more years' treatment, mainly with sulphones, yet none has yet had negative skin smears The periods under treatment are $7^1/_2$, $6^1/_2$, $5^3/_4$, $5^1/_2$, 5, $4^1/_2$, $4^1/_4$, $3\,^3/_4$, 3, and 3 years

Many have had bouts of erythema nodosum leprosum, sometimes with enormous numbers of painful transient erythematous nodes high fever, neuritis, insomnia, and depression Such episodes may continue for weeks or months, even if sulphone is immediately stopped, and require skilful management Corticotrophin and cortisone have a dramatic effect on the symptoms, but do not terminate an attack, and in view of the risk of aggravating the underlying disease they should be used only when absolutely necessary and when sulphone is given concurrently The longest period on corticotrophin or cortisone for any one patient at this hospital has been $13^1/_2$ months (three courses of $4^1/_2$ months)

In some patients the brunt of the reaction is borne by peripheral nerves, and pain and tenderness necessitate reduction or stoppage of sulphone until the neuritis subsides If muscle function is threatened, an operation must be undertaken to strip the nerve sheath from the swollen portion of nerve Two patients are particularly subject to swelling and tenderness in one or both median nerves at the wrists, causing the symptoms of the carpal tunnel syndrome [3]—paroxysmal tingling and burning pain in the palms and first three fingers, occurring chiefly at night Leprosy has not previously been recorded as a cause of this syndrome In one of these patients one hand is so severely affected that the median nerve is to be decompressed at the wrist

In two patients the principal complaint during erythema nodosum reactions is arthralgia affecting the knees, and another has iridocyclitis Borderline (dimorphous) cases are particularly liable to the sudden development of a reactional phase with fever, œdema redness and swelling of all skin lesions, neuritis, and rapid increase in bacilli as judged by skin smears One ex patient had such a lepra reaction three to four weeks after beginning sulphone therapy, and was desperately ill for six weeks, by the end of which time he was emaciated and weak, and had severe wasting of the intrinsic muscles of his hands together with bilateral dropped foot

Isoniazid has been given a trial, alone [4] and with sulphone,[5] but has proved disappointing Thiacetazone (TB1) has been found to have some value but is less active than sulphone and is reserved for patients who cannot tolerate the latter Thiacetazone in combination with isoniazid has not given better results than by itself Two other drugs tried are 'Ethizone' (TB3)[6] and diisoamyloxythiocarbanilide

Care of Hands and Feet

As most of the patients have some degree of peripheral nerve damage, minor injuries are slow to heal and are liable to lead to trophic ulceration New shoes are dangerous unless they are made to measure by an expert Analgesia of the hands makes it difficult to guard against burns especially when cooking and hot-water bottles have had to be strictly forbidden because they are liable to burn the feet or legs If peripheral nerve damage has advanced sufficiently to cause weakness of the muscles of hands or feet, daily physiotherapy is necessary to prevent contractures. Paralysed muscles call for tendon transplantations

Intercurrent Diseases

Though the number of beds is small a wide variety of intercurrent disorders have had to be treated during the three and a half years of the hospital's existence

Surgical operations (performed by Mr H R I Wolfe at the Hospital for Tropical Diseases or by the surgeons at University College Hospital) have included bilateral oöphorectomy for chocolate cysts, osteotomy of the femur for chronic arthritis of the hip lobectomy for bronchial carcinoma hæmorrhoidectomy radical antrostomy and extensive skin grafting for severe burns contracted before admission Medical problems have included paranoid schizophrenia hysteria, diabetes mellitus idiopathic epilepsy renal amyloidosis pyelitis and various helminthic diseases and acute infections.

PERSONAL PROBLEMS

Perhaps in no other disease is the doctor patient relationship so important as it is in leprosy for not only is progress slow and treatment prolonged but the sufferer is liable to periods of frustration and despair and to periods of prolonged physical suffering The patients who despair have to be given courage to go on those who are worried by domestic or other difficulties need advice; those who quarrel have to be reconciled to each other; those who break regulations have to be gently yet firmly reproved those who are in pain need relief—and this is especially difficult in a long standing disease like leprosy because the best analgesics are habit forming and therefore must be avoided if possible For severe nerve pain I have found small intraneural injections of procaine valuable All these troubles make great demands on the nurses and call for much patience and understanding on their part

The regulations regarding notification differ from those in South Africa and Australia in that they contain no statutory powers whereby a patient can be removed to or detained in hospital against his will This means that our patients can discharge themselves from hospital when they so desire and much time has to be spent persuading those who want to leave hospital that it is to their advantage (and to that of their families) to remain as long as their disease is active Not only may dangerous ophthalmic or neuritic reactions appear suddenly and cause permanent damage if not reported early or if not handled expertly but in spite of warnings patients living at home repeatedly burn their hands or injure their feet Mothers of young children find separation hard to tolerate but have to be persuaded to remain in hospital for their children's sake An additional reason for such a patient not returning home before she is cured is the fact that pregnancy must be avoided at all costs not only does it seriously aggravate the disease but it involves all the emotional strain of having the baby sent away immediately after birth Finally experience in handling outpatients has shown that some fail to report regularly for examination and laboratory tests and a few cannot even be relied upon to carry out treatment In an extreme case the patient deliberately discontinued treatment for six years, with disastrous results to herself[7] Fortunately such an occurrence is less likely now that leprosy is notifiable and the Ministry's adviser keeps the notified cases together with their families under review

THE OUTLOOK

Until such time as research workers discover how to cultivate the leprosy bacillus either in vitro or in vivo the clinician must make use of drugs which have a tuberculostatic activity or he may turn to the pathologist for guidance as to how immunity manifests itself in leprosy and as to how the body's defence mechanism can be stimulated so that the macrophage cells no longer protect the bacilli which multiply within them Research workers in many parts of the world are opening up new avenues of thought and endeavour—Hanks and Gray[8] with their work on the rat leprosy bacillus Suter[9] with his studies on the intracellular parasitism of tubercle bacilli Campos[10] with his work on B.C.G vaccination in the prophylaxis of leprosy Lowe and McNulty[11] with their observations on immunology Ridley[12] with his investigations on the significance of antibody, and others too numerous to name

The Jordan Hospital because it can combine detailed clinical observation with the fullest possible pathological control, is in an unrivalled position to develop and perfect new methods of treating this challenging disease

I would like to thank Sir Neil Hamilton Fairley Sir George McRobert and Prof A. W Woodruff for permission to publish details of some of their patients.

POLIOMYELITIS VACCINE

MEDICAL RESEARCH COUNCIL PLANS

THE Medical Research Council have announced that a limited amount of poliomyelitis vaccine of the kind used in the United States will be available to them this year Sufficient will be allocated for the vaccination of small groups of children in a few centres in Great Britain and Northern Ireland in which there are laboratories studying the poliomyelitis virus The arrangements will be made locally The response to the vaccine will be judged serologically and compared with other information obtained from laboratory tests This course the council add is necessary for planning the most effective use of the larger quantities of vaccine which are likely to become available in this country in 1956 They emphasise that the vaccine is at present available only for these limited purposes and that applications for inoculation cannot be entertained

SUPPLIES IN THE UNITED STATES

It is expected that there will not be enough vaccine to meet the first big demands in the United States, but by the end of the summer supplies will probably be adequate[13] President Eisenhower has directed his Secretary of Health Education, and Welfare to organise a voluntary system of allocating the vaccine It has been suggested that Congress should take steps to prevent a black market in the vaccine The manufacturers have undertaken to supply the National Foundation for Infantile Paralysis with sufficient vaccine to immunise all school-children in the first and second grades throughout the United States and its territories A booster dose will be offered to the 500,000 children vaccinated in last year's trial

REACTIONS IN OTHER COUNTRIES

Dr Herdis von Magnus, of the State Serum Institute in Copenhagen, is reported[14] as saying she had heard from Dr Salk that the results of further investigations were even more favourable than those already published She found it difficult to understand objections raised in Britain, France, and Norway that the vaccine would not be as successful in Europe as in the United States In Geneva Dr A M Payne, of the World Health Organisation's division of communicable diseases, pointed to the as yet little known properties of the vaccine, and said he thought that poliomyelitis was not yet beaten In Paris, the French Minister of Health said that France would mass-produce a similar vaccine developed by Prof Pierre Lepine[15] The Swedish board of medicine have ordered enough American vaccine for 100,000 people A Swedish vaccine, using human and not monkey tissue, will also be given

A COURSE IN FAMILY PSYCHIATRY

PSYCHOSIS is found in about 0 5% of the population, mental deficiency in about 1% What fraction these conditions represent of the total mental illness in the country is hard to estimate, but neuroses of varying degrees of severity are so common that it cannot be a large one Patients with psychosis and mental defect fill nearly half our hospital beds, and in industry neurosis is responsible for about a third of all absences from work due to illness[16]

It is now generally held that the public health service should begin to develop a formal mental-health programme[17], and there are signs of a growing interest in this subject among school medical officers This was illustrated at a refresher course in child psychiatry arranged by Dr J G Howells, and held at the end of March by the child psychiatry department of the Ipswich group hospitals In this, the second year of the course, those taking it included 13 school medical officers, 9 general practitioners, 3 psychiatrists, and 2 pædiatricians The general practitioners came mostly from the area of the East Anglian Regional Hospital Board, but the school doctors came from all parts of the country, including Scotland. Last year only 16 people attended the entire course, and 10 came for parts of it, this year 27 members were attending full-time, and only 2 or 3 part-time The growth of interest among general practitioners in the psychiatry of childhood is shown by the fact that in 1947 only 3% of the children attending the department's clinic were referred by their family doctors now nearly 70% of them are referred from this source Dr Howells estimates that if about 5 general practitioners attend the course every year, by the end of ten years most of the partnerships in the area will have been represented (More still would attend, he thinks, if they were able to claim expenses for putting in a locum during their absence, but at present the Ministry of Health is not willing to meet this expense for doctors attending courses arranged by "other persons" than universities and medical schools, although the 1946 Act permits such payments to be made)

The course lasts four days, the first three sessions being concerned with the three main reactions—neurotic, delinquent, and psychosomatic—of children to emotional stress The fourth session dealt with adolescent reactions, and in a fifth session all these subjects were brought together in a consideration of the family as a whole. The last three sessions covered speech difficulties, epilepsy, and the emotional aspects of mental deficiency, cerebral palsy, and psychosis At these sessions, Dr Howells, as tutor, demonstrated a long case, and after a pause for questions and discussion, summed up He then showed short cases relative to the same general theme, and again allowed a short period for questions These lecture sessions alternated with demonstrations, conducted by members of the psychiatric team of the department, on psychometry, play therapy, bibliotherapy, and record-keeping

"Bibliotherapy" in this context means the use of reading matter for therapeutic purposes, and books and papers used in this way were shown at the demonstration The department lends parents articles and books on childhood problems, and also keeps a small lending library of children's books. At the end of the play session each child can borrow a book, which he brings back to exchange for another at the next session The stories help to keep the child in touch with the clinic between sessions and make good topics of conversation All members of the course had been supplied with a list of books recommended for their own reading, and these too were shown at the demonstration

Finally, a demonstration had been arranged, at one of the hospitals of the group, of the electro encephalographic examination of a child Attendance at demonstrations was kept small and wieldy by splitting the members of the course into four groups, and repeating the demonstrations for each group in turn From the interest taken and the questions asked it was clear that the course was proving useful even to those already engaged in psychiatry The lectures were well founded in experimental work, and the point was repeatedly made that the child cannot be treated apart from his family as Dr Howells put it, "the neurotic reaction of the child is a reaction to an emotional battering from the neurotic or disturbed adult"

This seems at present to be the only course of its kind in the country

Medicine and the Law

Bogus Doctor Fined

A FORMER medical student has been fined £100 for forging a letter purporting to show that he was a qualified doctor[1]

Reginald Morgan Ford, aged 35, pleaded guilty to forging a letter from the chief clerk of the General Medical Council purporting to show that he was a graduate in medicine and surgery of the University of Bristol, held the degrees of M B and CH B, and was registered in the Medical Register

Ford had been accepted as an assistant and subsequently produced the forged letter to support his claim to be a doctor He never purchased dangerous drugs He had entered Bristol University in 1947 but was later expelled for a breach of discipline On Ford's behalf it was stated that he had offered to repay money paid for his services while posing as a doctor but the principal had declined the offer because he was satisfied with his work whether practised under deception or otherwise

The Recorder, in passing sentence, said that until he heard the mitigating circumstances he had thought it would be a case for a prison sentence, but he felt after hearing them that no good purpose would be done by sending him to prison "There is no doubt," the Recorder told Ford, "that you were in possession of sufficient skill to satisfy those who became your patients and you appear to have been very careful not in any way to abuse the professional position you wrongly assumed. Apart from being a bad example you have really done no harm"

Conferences and Congresses

SYMPOSIUM ON LIVER DISEASES

A SYMPOSIUM on Modern Aspects of Liver and Biliary Disease was held on March 28–April 1 at the Postgraduate Medical School of London The meeting was planned by Dr SHEILA SHERLOCK who arranged a comprehensive course of lectures, demonstrations, and discussions of subjects with practical applications in general medicine and surgery Dr CHARLES NEWMAN dean of the postgraduate school, welcomed more than 60 participants including Dr J CAROLI and Dr V SCHWARTZMANN from Paris, Dr S MADSEN from Copenhagen Dr G A MARTINI from Hamburg and Dr R MANGOLD from Lausanne

Jaundice

The first day s programme concerned problems associated with jaundice and Prof E J KING acted as chairman

Prof N F MACLAGAN reviewed the range of liver function tests and pointed out that certain tests might be positive in diseases which were not primarily hepatic including heart-failure chronic rheumatism malaria and glandular fever A poor prognosis was associated with serum albumin levels of less than 2 g per 100 ml in medical cases and the failure of an increased prothrombin time to respond to vitamin K injections was an unfavourable sign in obstructive jaundice For routine use he recommended examination of the urine for bilirubin bile salts and urobilinogen estimations of serum bilirubin and alkaline phosphatase levels and thymol flocculation and colloidal gold tests Measurement of serum proteins and bromsulphalein retention should be added if indicated

Dr Sherlock classified jaundice and discussed its clinical management She stressed the significance of pain and pruritus in the history and the finer points which might emerge from a thorough physical examination. In the treatment of acute hepatitis she considered that diet should be dictated by the patient's appetite and that the inclinations of the patient should be taken into account in the early stages of mobilisation In chronic obstructive jaundice methyl testosterone for pruritus, fat-soluble vitamins by injection and calcium tablets were of value

Dr F O MACCALLUM said that the lack of a susceptible animal host hindered studies of virus hepatitis Virus A causing infective hepatitis was present in blood and fæces but a carrier state had not been proven Serum hepatitis was caused by virus B which had only been isolated from blood and a carrier state of uncertain duration had been demonstrated Gamma globulin might be given to contacts of infective hepatitis but was of dubious value in serum hepatitis. The two viruses were immunologically different

The significance of positive flocculation tests as an isolated finding after hepatitis was discussed and it was agreed that a careful follow up was indicated but no active measures need be taken Blood-donors should be rejected if they had had an attack of hepatitis Carriers may not have had overt hepatitis and the duration of the carrier state was unknown

On the question of cholangiolitic hepatitis Dr Sherlock remained unconvinced

Dr Caroli pleaded for the wider use of peritoneoscopy in the differential diagnosis of jaundice Prof IAN AIRD considered that this technique demanded great experience and admitted that the type of jaundice was often obscure at laparotomy By serial sampling of blood and duodenal contents following an intravenous dose of bromsulphalein Dr Caroli had found that the excretion time was delayed in obstructive jaundice and normal in hepatitis and he advocated this test in cases of doubt

Cirrhosis and Portal Hypertension

Professor Aird was chairman when Dr Sherlock introduced this subject and explained that the term cirrhosis ' should be restricted to conditions in which the lobular architecture was disturbed A similar histological picture resulted from many causes, because of the limited response of the liver to injury while the clinical features were dominated by those of portal hypertension and inadequate liver-cell function

Current views on the pathogenesis of portal hypertension and its clinical consequences (portal collateral circulation, splenomegaly, and hæmatological changes) were ably summarised by Dr P C REYNELL. In 20% of patients with portal hypertension there was no liver disease and the cause was usually an obstructive lesion of the portal vein

The technique of percutaneous transplenic portal venography was demonstrated by Dr Sherlock Dr R E STEINER, and Dr M D TURNER. The application of this investigation to the diagnosis of portal hypertension and its special use in preoperative assessment were discussed Dr W H J SUMMERSKILL and Dr G A MARTIN showed that the pressure in an occluded hepatic vein, measured through a cardiac catheter provided an alternative index of portal pressure and that other information could also be derived from catheterisation of the hepatic veins A normal occluded hepatic vein pressure with evidence of portal hypertension, was found in patients with thrombosis of the portal vein

Prof R MILNES WALKER discussed the management of portal hypertension The danger of severe hæmorrhage was the only indication for major surgery, but poor liver function or an unsatisfactory general condition might preclude operation Surgical treatment should not be considered for the relief of ascites, but this complication did not necessarily contra indicate operation A preliminary portal venogram was a great help and, when practicable an end to-side portacaval anastomosis was the operation of choice Other portal systemic shunts often became occluded and gastric or œsophageal transection although without operative mortality, was often followed by a recurrence of hæmorrhage

During the discussion it was agreed that the incidence of hepatoma in cirrhosis was 5–15% Most speakers were in favour of eliminating alcohol from the diet of all patients with cirrhosis Dr Sherlock considered that ascites was a contra indication to portacaval anastomosis in cirrhosis but Prof H RODGERS preferred to be less dogmatic. Professor Aird thought that improvement after such an operation could often be attributed to the increased collateral circulation which was encouraged.

Radiology of Biliary Tract

With Prof J MCMICHAEL in the chair, Dr D SUTTON spoke on the radiology of the biliary tract He advocated the use of the intravenous contrast medium Biligrafin especially after cholecystectomy in preference to the oral method and he stressed the importance of cholangiography during operations involving the biliary tract Percutaneous trans-hepatic cholangiography in obstructive jaundice was hazardous because of the risk of biliary peritonitis

Dr Caroli pointed out that biligrafin excretion was related to liver function and though radiology should always be attempted serum bilirubin levels of above 3 mg per 100 ml were seldom compatible with a satisfactory picture

Ascites

In a debate on the problem of ascites in liver disease Dr R I S BAYLISS said that the primary defects of lowered plasma albumin concentration and increased portal venous pressure did not alone always explain the accumulation of fluid Additional factors introduced by the movement of sodium and water into the peritoneal cavity were the diminished output of sodium in urine, sweat, and saliva, possibly associated with increased aldosterone secretion and diminished destruction of other adrenocortical steroids Altered posterior pituitary antidiuretic hormone activity and decreased renal blood-flow might also be of significance

As for treatment, Dr A PATON considered that surgical measures designed to reduce portal venous pressure were dangerous, and methods directed at raising colloid osmotic pressure had only a transient effect The best treatment was paracentesis and then a low-sodium diet (less than 22 m eq Na daily), mercurial diuretics, and ammonium chloride Patients with ascites due to temporary impairment of liver function (alcoholic debauches or gastro intestinal hæmorrhage) responded rapidly to correction of the precipitating factors, and ascites was controlled in most other patients by the conservative régime he had outlined Failure may be due to faulty supervision "Active" liver disease and malignant hepatoma were often associated with intractable ascites which resisted treatment and progressed to a terminal dilution hyponatræmia

During the case demonstrations, it was shown that a good response to treatment was often related to an adequate urinary sodium output in the control period and that relaxation of the régime could sometimes be allowed without deterioration

Dr M D MILNE advocated a combination of potassium and ammonium chlorides in the treatment of ascites, for mercurial diuretics often caused loss of potassium, and Dr Bayliss pointed out that altered capillary permeability might be an important factor in the pathogenesis of ascites

Needle Biopsy

At this session Prof L J WITTS was in the chair Dr Sherlock stressed the safety of the procedure (reported mortality 0 17%) and its wide application in the diagnosis of liver disease, pyrexia of unknown origin, miliary granulomata, reticuloses, and amyloidosis Dr C V HARRISON exhibited biopsy specimens taken from patients in whom the clinical findings were equivocal and explained the histological criteria upon which the diagnosis was made

Hepatic Coma

Dr Sherlock described the mental changes and abnormalities of the motor system in hepatic coma A characteristic electro encephalogram might be found, but was not specific Various factors, either affecting liver function adversely or increasing the nitrogenous material in the intestine, might precipitate the disorder She attributed the syndrome to toxic nitrogenous substances from the portal vein (portal-systemic encephalopathy) and advocated conservative treatment based on the withdrawal of protein, the administration of aureomycin (to reduce bacterial activity in the intestines), and maintenance on glucose

Mr A G RIDDELL also thought that a toxic nitrogenous substance in portal blood was responsible for the neurological disturbance and put forward evidence to incriminate ammonia as the cause in animals and in patients with portacaval anastomoses He referred to the arrest of hæmorrhage by œsophageal tamponage Dr Summerskill demonstrated the relationship of the neurological signs to liver function, portal systemic collateral circulation, and dietary nitrogenous substances Although many signs of hepatic coma could be induced by nitrogenous substances and improved on protein withdrawal, he hesitated to ascribe the whole syndrome to this

During the discussion, it was shown that methionine might precipitate the neurological syndrome without alteration in blood ammonia levels and that its adverse effect was retarded by aureomycin Mr Riddell had found glutamic acid helpful in patients with chronic signs and portacaval shunts, but it had little effect in coma due to liver failure It was considered that methionine had no place in the treatment of liver disease

Some Other Subjects

Colonel W R M DREW considered hepatic *amœbiasis and leptospirosis* both of which were of importance in the United Kingdom The liver was involved in 5-10% of patients with intestinal amœbiasis Jaundice was rare and he did not believe "hepatitis" occurred, only abscess formation Radiology was often crucial in diagnosis Chloroquine was the best drug

Dr A E CLAIREAUX classified the features of *neonatal jaundice* as non-obstructive, in which hæmolysis and inability of the liver to deal with products of hæmolysis were of importance, and obstructive In the second category he included the "inspissated bile syndrome" (which might occur in several diseases) and hepatitis, but he agreed that the classification was not rigid The differential diagnosis of congenital obliteration of the bile duct and viral hepatitis was difficult There was a growing awareness of hepatitis, possibly associated with a carrier state in the mother, as a cause of jaundice in the neonatal period

Dealing with the clinical aspects of neonatal jaundice Dr J W GERRARD said prognosis was difficult and biliary obstruction was sometimes compatible with a long course, with xanthomatosis and hypercholesterolæmia He mentioned two interesting dental manifestations—green milk teeth due to deposition of bile in the dentine and enamel hypoplasia due to poor calcification

Jaundice during pregnancy, said Dr Martini, was either jaundice *of* pregnancy, a relatively uncommon occurrence in toxæmia and associated with only slight bilirubinæmia, or jaundice *in* pregnancy This was usually due to viral hepatitis and, contrary to accepted views, was seldom a severe illness, although fœtal mortality and miscarriage were common in the late stages of pregnancy Jaundice due to gall stones might also arise during pregnancy

Dr W R PITNEY, discussing *coagulation defects* in liver disease, explained that capillary function, platelets and plasma coagulation factors may all be affected in liver disease The commonest defect involved the "prothrombin complex" (prothrombin and factors v and VII) and separate assays were often desirable because the Quick one stage prothrombin-time was relatively insensitive to the abnormal prothrombin levels which might occur in all types of liver disease

Dr Caroli showed an excellent film in which perfusion of the gall bladder was used to demonstrate changes in tone of the *sphincter of Oddi* Reflux into the pancreatic duct occurred in response to fatty meals, high perfusion pressures, or atropine Morphine prevented reflux at high perfusion pressures Surgical measures designed to correct "hypertrophy" of the sphincter were therefore useless

Professor McMichael said that slight elevation of serum bilirubin levels was common in *heart failure* and that "cardiac cirrhosis" (with deranged liver function tests) might occur, especially with tricuspid incompetence Jaundice may be severe, and hæmolysis from pulmonary infarcts may be one cause

Dr Sherlock demonstrated cases of *hæmochromatosis* and stressed the family history, the occurrence in males, the alteration in testicular function, and the incidence of cirrhosis and hepatoma She recommended venesection (500 ml weekly) to remove iron from the body, with careful observation of hæmoglobin and plasma rotein values. Testosterone implants and insulin were aluable supplements

Dr Milne discussing *hepatolenticular degeneration* ointed out that this condition could be distinguished om chronic portal systemic encephalopathy by the ecessive inheritance the age-incidence the absence of luctuation in the signs the Kayser Fleischer rings the mino-aciduria and the abnormal copper metabolism low serum-copper and high urinary copper values) A pecific defect of cæruloplasmin allowed unstable copper o be deposited in the tissues and this produced the clinical features of the disease Copper could not be excluded from the diet but potassium sulphide diminished absorption The best treatment was dimercaprol potassium sulphide and a high protein diet and this might prevent deterioration in asymptomatic cases.

Summing up Professor McMichael said he was always interested in those points which failed to conform to an accepted theory for he felt that they often held vital clues The conference had been a success and he referred particularly to the considerable contributions by Dr Sherlock

Public Health

MALIGNANT DISEASE OF THE RESPIRATORY SYSTEM

A STATISTICAL SURVEY

F L BRADSHAW

F.I.A

THIS survey was prompted by Dr Evarts Graham's recent lecture[1] on the Ætiology of Bronchogenic Carcinoma. He based his observations largely on statistical material obtained in the United States and it seemed likely that a similar study of statistics for England and Wales might give rather different results since the average age of our population is appreciably greater

All the figures are taken from part I of the Registrar General's annual statistical reviews Descriptions of cancer—i.e., malignant neoplasms—and the six broad classifications of its sites are those given in the review for 1952 The survey covers the twenty year period 1932–1952 using figures for selected years only Population statistics between 1940 and 1948 were disturbed by the war and accordingly it seemed better to use figures for three of the early years of the period and those for the last five years These, together with figures for two years in the middle of the period provide a reasonably accurate picture of the general trend between 1932 and 1952

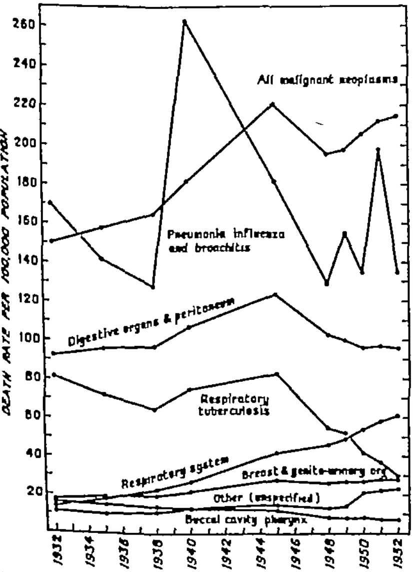

Fig 1—Deaths per 100 000 population in England and Wales from malignant neoplasms and diseases of the respiratory system from 1932 to 1952.

COMPARISON WITH OTHER DISEASES

Fig 1 shows the number of deaths per 100 000 of the male population of England and Wales from cancer and certain diseases of the respiratory system. The latter are shown so as to bring the graph broadly into line with that in Dr Graham's fig 1 The different age distribution in this country explains why our death rates are very much higher than those of the United States The fall in the death rate for respiratory tuberculosis from over 80 to 30 roughly corresponds to that in the United States The curve relating to pneumonia influenza and bronchitis is difficult to interpret owing to its violent fluctuations yet here too there has undoubtedly been a fall though a very much smaller one than in the United States

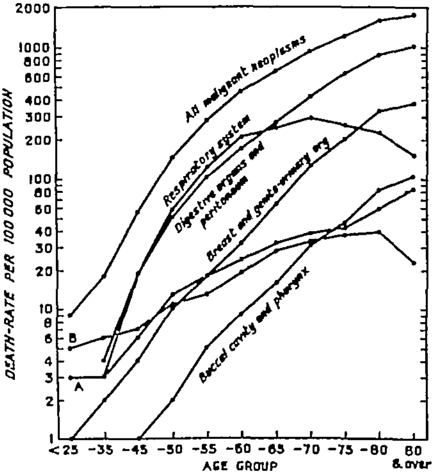

Fig 2—Deaths per 100,000 population in England and Wales from malignant neoplasms in 1952 (by age-groups) (A—other unspecified sites ; B—lymphatic and hæmatopoietic tissues.)

The curves for malignant neoplasms show that the steepest rise in death rates has been in cancer of the respiratory system Cancer of the digestive organs is however still the greatest destroyer of life Cancer of the breast and of the genito-urinary organs shows a steady increase and cancer of other and unspecified organs shows a rapid increase in the last five years Cancer of the buccal cavity and pharynx alone shows a decline

---

[1] Graham, E. A *Lancet* 1954 i, 1305

Fig 2 is constructed to show the *malignancy*, as distinct from the destructiveness, of the various cancer groups Assuming that senility is a considerable factor in all deaths after the age of 70, the malignancy of a disease may be assessed by its destruction of life before that age On this basis, cancer of the respiratory system is the most malignant of all the cancer groups, though followed closely by cancer of the digestive organs

The peculiar bend in the curve for cancer of the respiratory system, which results in it crossing the curve for cancer of the digestive organs after age 60, explains the lower over all death rate from respiratory cancer The two curves plotting cancer of other and unspecified sites, and cancer of the breast and genito urinary organs, exhibit similar features the former shows greater malignancy and the latter a higher over all death rate Cancer of the buccal cavity and pharynx (which has the lowest death rate of any of the groups) is lowest also in malignancy

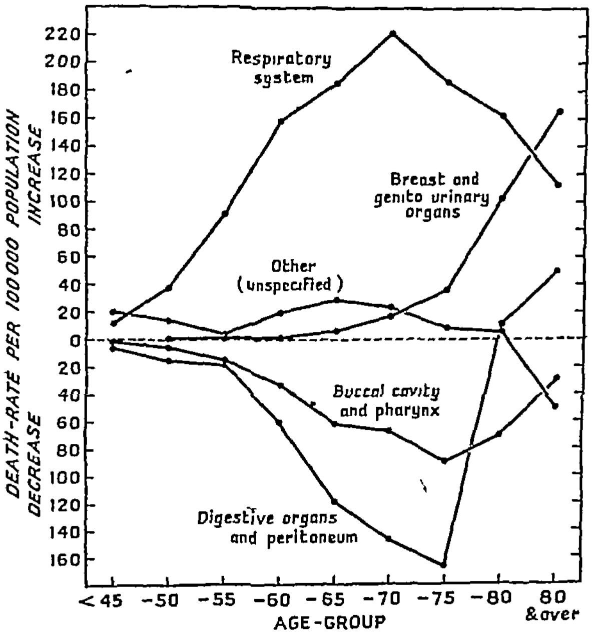

Fig 3—Changes in age-group death rates per 100 000 from various malignant neoplasms between 1932 and 1952.

Fig 2 shows the relative malignancies of the cancer groups in 1952 In 1932 these relative malignancies were very different, and fig 3 has been constructed to show broadly the changes which have taken place It shows for each of the groups the increase or decrease in the death rate during the twenty year period for all ages up to 45, and thereafter in the quinquennial age groups used in fig 2

Defining malignancy, as before, as the number of deaths caused before the age of 70, cancer of the respiratory system shows by far the largest increase in malignancy, whereas cancer of the digestive system—its present runner up in this respect—shows by far the biggest decrease Cancer of other and unspecified sites shows an appreciable increase in malignancy For cancer of the breast and genito urinary organs the increase is practically negligible Cancer of the buccal cavity shows a decrease throughout the whole of life

Our experience of cancer of the respiratory system follows very closely that of the male population of the United States, as revealed in Dr Graham's fig 1 During the period under review there was a very serious increase in the malignancy of cancer of this site On r hand, our experience of cancer of all the other

TABLE I—DEATHS PER 100,000 FROM CANCER AND RESPIRA DISEASES, 1952 COMPARISON BY SEX

Age and sex	Malignant neoplasms								Respiratory system
	All sites	Buccal cavity	Digestive organs	Respiratory system	Breast and genitalia	Urinary organs	Other and unspecified sites	Lymphatic and hæmatopoietic tissue	Tuberculosis
All ages									
Men	215	7	96	61	16	12	12	11	31
Women	185	3	81	11	67	5	10	8	13
Under 70									
Men	141	4	54	51	6	7	9	10	13
Women	117	2	40	8	50	3	7	7	12

sites is not unsatisfactory, because though the death-ra per 100,000 of our male population has increased quantitatively from 136 to 154, the malignancy has been reduced, and the corresponding death rate for ages under 70 has fallen from 92 to 90—a small reduction, but one of considerable economic, and no doubt medical significance

SEX DIFFERENCE

Another fact mentioned by Dr Graham is that bronchogenic carcinoma is about 6 times commoner *in men than in women This parallels our experience*: over-all and under-70 death rates for men in England and Wales are respectively $5^1/_2$ times and $6^1/_2$ times those for women Nor is the higher frequency of cancer in men confined to this one site it extends to all sites excepting only the breast and genital organs Moreover the over all death-rate from all diseases of the respiratory system (including tuberculosis but excluding cancer) was in 1952, about $1^3/_4$ times greater in men than in women and the death-rate for men under 70 was more than double that of women These figures, with those relating to cancer, are given in detail in table I

EFFECT OF VULNERABILITY

For some reason, men are more vulnerable to cancer on the one hand and to diseases of the respiratory system on the other, and these two facts may partly explain the high lung cancer death rate in men Moreover, the statistics show that during the period under review there has been a substantial reduction in both the destructiveness and malignancy amongst men

TABLE II—DEATHS DUE TO MALIGNANT NEOPLASMS IN MALE 1948–53

Causes of death	1948	1949	1950	1951	1952
All malignant neoplasms					
Total deaths	40,026	40 772	43 570	44,632	45 429
Death rate per 100 000	190	198	206	212	215
,, below 70	128	128	136	138	141
,, at 70 and over	1326	1354	1404	1441	1443
Malignant neoplasms of digestive organs					
Total deaths in year	20,970	20,629	20,420	20,405	20,175
Death rate per 100 000	103	100	96	97	96
,, ,, below 70	61	59	55	55	54
,, at 70 and over	796	782	782	790	761
Malignant neoplasms of respiratory system					
Total deaths in year	9,465	10,163	11,340	12 237	12,971
Death rate per 100 000	46	49	54	58	61
,, below 70	40	42	45	49	51
,, at 70 and over	146	168	194	215	227
Percentage of deaths below 70	82	$80^1/_2$	$79^1/_2$	79	79
Percentage of deaths at 70 and over	18	$19^1/_2$	$20^1/_2$	21	21

ll diseases of the respiratory system except cancer , so he considerable increase in lung cancer may be the esult of better treatment of other lung diseases The tatistics show that the reduction in the over all death ate for men from all diseases of the respiratory system, other than cancer, is 53 per 100 000 and in the death ate for ages under 70 is 99 per 100,000 Corresponding ncreases in the death rates from cancer of the respiratory ystem are 47 and 39 respectively

How far the present high death rate of men from cancer of the respiratory system is attributable, on the one hand, to the tobacco habit and, on the other hand to their general *vulnerability to cancer only future* research will decide What this survey does indicate is that either of these factors could explain the increased incidence of respiratory cancer since 1932

THE 1953 FIGURES

Since I *prepared these figures, statistics for 1953* have been published Table II covers the main features of the survey of the statistics for males during the six years ending with 1953 The trends already observed are continuing but there are certain aspects of the 1953 figures which give cause for satisfaction

(1) The over all death rate from cancer of all sites has fallen from 215 to 214 per 100 000 male population. The amount of the decrease is insignificant yet it is the first time a fall has been recorded Also the malignancy—i e , the death rate below age 70—shows definite signs of slowing up it has increased by only 1 per 100 000 whereas the average yearly increase in the previous period was nearer 5 per 100 000

(2) For cancer of the digestive organs, the fall in all death rates has continued Cancer of this site is still the greatest destroyer of life though in its malignancy it is surpassed for the first time in 1953 by cancer of the respiratory system

(3) It is difficult to find any satisfactory feature in the figures for cancer of the respiratory system yet here too there is a slowing up *in* the malignant death rate This is not apparent from the death rates themselves, but can be seen from the last two lines of table II which give the percen age of deaths below and above age 70 Over the six years he proportion below age 70 has steadily declined

---

LONDON'S WATER-SUPPLY

THE 35th report of the director of water examination Metropolitan Water Board, covers the six years 1947–52 and the water-supply to a sixth of the population of this country This is Colonel E F W Mackenzie s last report as director, and it bears throughout the marks of his wisdom experience and guidance through all the vicissitudes of war and of post-war reconstruction His earlier report, the 34th covered the eight years 1939–46 so that the second volume completes the account of his distinguished service with the board It is full of material of unique value to science far beyond the narrower interests of public health or water engineering

BIOLOGICAL DIFFICULTIES

The biological section deals with some of the broader conceptions of exploiting the natural water sources in the London basin Many of the reservoirs have accumulated sediment for over fifty years with some incidental small loss of storage capacity and retention time but the deposits have affected the algal fertility particularly during the summer when the reducing substances on the bottom tend to deoxygenate the lower layers of the water and impose chemical stratification to complicate the natural thermal stratification The seasonal overturns and the disturbance of stratification by rough weather are liable to embarrass the filters with algal scum and impart to the drinking-water unpleasant tastes which occasionally defy all treatment Constant assessment of the algal state and a certain amount of ingenious juggling with variable level draw-offs, kept these inconveniences to a minimum, but at other times it was necessary to resort to the more expensive application of copper-sulphate algicides. Colonel Mackenzie wonders whether a more biological outlook on the operation of reservoirs might have an important influence in reducing the financial loss and the nuisances resulting from excessive growths He seems to have been spared the problems of toxic pesticides and agricultural weed killers which are beginning to worry some users of overground water-supplies. The control of midges around the reservoirs has been much less effective; luckily they are non biting chironomidæ, and the local population are advised to live in philosophical symbiosis with the invaders

BACTERIAL CONTAMINATION

Medical interest flows naturally from the wider aspects of biology into the bacteriological section of the report. Some 45,000 samples have been examined each year and the chief interest centres upon the traditional indicator organism *Escherichia coli* Two of the many practical observations were that 99 2% of all the *E coli* specimens received were obtained in the first eighteen hours incubation, and that most of the false presumptives were due to *Clostridium welchii*, particularly in chlorinated waters Laboratory techniques for the rapid identification of *E coli* are discussed in detail before the report passes on to more considerations of public health. It is startling to realise that the 1931 milk borne epidemic of paratyphoid B in Epping is still reflected in the sewage effluent The readiness with which the organism can be recovered indicates the local persistence of a high symptomless carrier rate Such findings illustrate the importance of routine medical examination of all waterworks employees who might contaminate public water supplies and of *re-examination* after any suspicious illness The preliminary sorting was done with Vi agglutination tests. 2502 employees were examined and 7 3% showed Vi agglutination. All the positive reactors had at least three stool and urine examinations, and 3 men even endured duodenal intubation for examination of their juices. No enteric organisms were recovered The re-examination of 1817 employees after suspicious illnesses revealed 28 cases carrying pathogens, mostly *Shigella sonnei* and *Salmonella typhimurium* Such routine precautions are a counsel of perfection, but they are difficult to apply in smaller undertakings and with outside contractors labour

CHEMICAL CONTENT

The chemical section of the report deals in detail with the changing methods for estimating the hardness and other inorganic constituents of the waters, and goes on to describe an interesting little piece of detective work on the River Lea to incriminate the springs in the bed as the cause of wide variation in hardness in different reaches of the river Investigation of the average natural fluorine content in 50 sources of London s water-supply in 1949 showed that the northern wells contained much more fluorine than the southern group Those in direct supply included East Ham with 1 08 parts per million (p p m) Hadley Road with 1 11 p p m and Ferry Lane with 0·91 p p.m., whereas most of the Kent wells contained less than 0 05 p p m The differences may be of some significance to the current investigations *into fluoridation of public water-supplies. This* section of the report ends with a description of the use of disodium hydrogen phosphate ($Na_2 HPO_4, 12H_2O$) as a tracer for detecting the flow of underground waters, particularly where pollution is suspected The method was found to have many advantages over the use of colouring materials, common salt or lithium chloride provided that laboratory facilities are readily available

CLARIFICATION

Research into the clarification of river derived supplies was continued in the full-scale experimental plant at Kempton Park The problem was not so much concerned with inert matter which settled to the reservoir floor but with the removal of suspended algæ. The experiment proceeded in three stages using respectively al sulphate, iron coagulants, and aluminium sulphate assisted by activated silica The relative advantages between slow sand filtration and coagulation processes remain to be assessed after extended trials Investigation was also carried out in the use of aluminium pipes and domestic utensils. Such pipes are discouraged, but aluminium utensils are reasonably satisfactory provided that they are first well washed out and then allowed to develop their own protective coating

CHLORINATION

The post-war years have seen radical changes in the technique of chlorination The longstanding practice of chloramine treatment has given place to superchlorination, of a degree where the dose is more than sufficient to disinfect the water without however satisfying the full chlorine demand The element of dechlorination can therefore be said to be self-induced, and in recent years there has been virtually no chlorine in the water supplied to London A dose of 1 p p m to the filtered water yields a residual of 0 3 to 0 4 p p m within a few minutes, and disappears during an hour's contact The necessity for prechlorination is obviated, and the bacteriological and physical quality of the water passed to supply is better than ever before, besides saving over £12,000 a year in chemicals A progressive policy has been carried out at all the wells for installing contact tanks, which incidentally serve as balancing tanks, to the combined joy of both the medical and the engineering interests

EMERGENCIES

The importance of these safeguards is emphasised by accounts of the accidents which have happened during the period covered by the report The flooding of the Lea Bridge works in 1947 temporarily deprived a large area of east London of its water-supply and presented many difficulties in restoring a safe supply The leakage of the public sewer into the Crayford well in 1950 was an event which would have had very serious consequences had the control measures not been so efficient But in spite of all the care exercised at the waterworks, the human element in the distribution can defeat the defences by unauthorised cross-connections Instances are described of steam, and even paraffin oil, coming out of consumers' cold-water taps, as well as of cross connections with impure supplies Constant inspection is the only answer to these risks, which are fortunately rare

---

Population Changes

The United Nations Statistical Office has just published its *Demographic Yearbook* for 1954,[1] which gives the latest news of the world's population trends The tremendous task of gathering, analysing, and arranging details from all over the world has been accomplished with striking speed and many 1953 figures are included Moreover, the statisticians have added an assessment of the limitations of each set of data, taking into account, for example, comparability and differences introduced by variations in the statistical habits of the countries concerned

The section on births includes tables setting out the number and rate of births classified according to the age of the mother The birth-rate per 1000 population is lowest in Western Europe (from 15 to 20), and one of the highest 1953 rates was in Burma (49 2) The 1953 birth-rate in the United States was 24 7, almost identical with the provisional rate for India in 1952 (24 8) and rather more than the 1953 rate for Japan (21 5) The tables in the yearbook illustrate how in the past thirty years birth-rates in Western Europe have fallen greatly, the lowest points being reached just before and during the late war

For this country the tables dealing with the age of mothers show that younger women are nowadays producing more children than they did before the war one of the chief reasons is that more women are having children in the first few years after marriage than was the case before the war

In England Now

A Running Commentary by Peripatetic Correspon

OUR medical painters are gaining in competence have they lost in the process some of the careless which made their earlier shows so lively ? The exhibition of the Medical Art Society, in progress Walker's Galleries[1] until April 30, is relatively sedate A B Hewlett's brilliant greens and meticulous beckon in the first room and this time he has achieved in *The Station Approach*, a really fascinating pattern—of garden, roadway, bold pink signal-box, and rolling hills into which a neat cow and a neater railway train are nosing their way, while a man in the foreground has leisure to drink beer He has certainly earned a drink, for every plant in his garden (possibly Eden) is flourishing in exact pace with its neighbours, and there is not a weed to be seen I was disconcerted, however, to find that I could not, for once, identify the flowers in the border chrysanthemums perhaps ? We must hope that Hewlett is not losing his usually (and unusually) firm grip of his subject Very different in technique is F Forty's *Forteleza da Sao Joao de Estoril*, where the pale yellow building, in its circle of bluish yaccas, seems to have floated down from the heat-shaken blue of the sky, In G Crosby's *Provençal Vegetable Stall*, yellow heat streaming beyond a dark archway tells of another hot day , but R A Beaver's *Playground, Cumberland Market* is very cold indeed The little black figures against the pale colours of this amusing painting seem to be crying out for pen-and-wash, however, rather than oils, T Holmes Sellors has noticed some pleasing reflections in his window, in *Interior at Night*, and Isabel Wilson has done a useful best to find colour in the interminable fastnesses of *Colcherne Road* H Elliott Blake has abundant colour to hand in *La Petite Auberge*, and has used it with discrimination and skill A J Edelsten's *East Lyn Valley*, with its warm-coloured earth and pale grass, and B N Brooke's dark old lock-gates in the shadowy dun countryside of *Lapworth* both gave me pleasure , and so did the small bright *Storm over Meil* and *Officer's Mess, Maynamati* of J F Stokes In *Still Life*, N Ashton has got a raw cabbage and an onion to the life, rather consciously grouped with half a glass of white wine and some other vegetables

Portraits make a good showing this year , and the palm, as far as I am concerned, goes to E W Peet for his painting of *Dr E W Ainley Walker* Sir Philip Manson-Bahr, president of the society, has been splendidly drawn by René Michelmore, who is also responsible for two other good portraits—*Lisa* and *Head of a Negro* The catalogue suggests that Josephine Roth's drawings of *J D Allan Gray, Esq , T.D , F R C P E , D P H* , and of *Horace Joules, Esq , M D , F R C P* , depend for interest on a plethora of diplomas, but they are, in fact, very good crayon portraits , and R O'Meara's yellow-lighted side view of *Dr R N McKinstry* is another clever and agreeable little likeness There was not much abstract art about I suppose our profession is not much given to abstractions N Newman in *Reverie* has attempted, it seems, a rapid review of Greek art and the art of Henry Moore and Salvador Dali It is perhaps not surprising that the partners in this ambitious programme had failed to compose themselves comfortably in the space available Among the few three dimensional exhibits there is a pleasing *Bitch and Pups* in glazed pottery by A. C Dalzell and a chunky little *Morris Dancer* on a hobby horse, carved in wood by G Sparrow Sparrow, it may be remembered, is the unique humorist who likes drawing his own hunting prints He has two splendid ones in this time—*Meet of Royal Buckhounds, 1810*, and *Tommy's Stables* Both are nicely mounted in old maple frames, and would make a handsome addition to any lady or gentleman's parlour

* * *

The Salk poliomyelitis vaccine has arrived Even before details of the elaborate and, I believe, careful experimental work have been presented to any competent scientific society, television, radio, banner press headlines, and 4 complete pages of the *New York Times* have informed the public of its wonders The names of Salk and Jenner are on the lips of countless citizens. Already anxious parents are demanding the vaccine for their children and worried administrators are requesting Presidential action to ensure its fair distribution It is difficult for laymen here to see the risks of poliomyelitis in their correct perspective There are 16,000 cases a year; a quarter of the cases have paralytic symptoms and of these only a further quarter have permanent paralytic sequelæ The risk of a child being killed or maimed by car accidents is incomparably greater

---

[1] 118 New Bond Street, London, W 1

When I arrived in New York I saw everywhere huge posters which told me ' Save your child from Leukæmia—give to the American Cancer Society It was fairly easy for me to see this appeal in perspective but a great deal less easy for the average parent The research foundations of America support an enormous amount of valuable and useful research, and in turn they are most generously supported by the public Unfortunately the public is more generous when its emotions have been stirred; and I don't myself believe that support for research should be obtained at the cost of arousing unnecessary fear

* * *

The peripatetic correspondent[1] who confessed to his ignorance of the Heat Barrier made the usual mistake of failing to consult the literature This obviously is the flame belt that divides the two hemispheres of Venus and allowed the simultaneous development of Theron and Treen civilisations. It was first fully described by Dare et al[2] and subsequent references in the literature are too numerous to quote Should the peripatetic correspondent have difficulty in obtaining the original paper an arrangement might be reached with the progeny of the present writer for the loan or exchange (with similar scientific material) of a genuine first edition

* * *

Our ward telephone rang the other day—it was a lady asking how Mrs Colby Brown was getting on after her appendicectomy Sister replied that the patient was doing famously and would shortly be sent home. Asked for her name, the lady replied Well Sister, this is Mrs. Colby Brown You're all so busy I just don't like to bother you on the ward rounds.

* * *

Last week I bought a book on motoring The chapter on Motor-cars and Health is by Sir Henry Thompson, F.R.C.S In it he writes:

> "The easy jolting which occurs when a motor-car is driven at a fair speed over the highway conduces to a healthy agitation; it acts on the liver to use a popular phrase which means only that it aids the peristaltic movements of the bowels and promotes the performance of their functions; thus accomplishing the good in this respect which arises from riding on horseback.

The date of publication is 1902

SIR JOHN BLAND SUTTON

Born April 21 1855

Rebellious spirit thou didst fight
Thy way from humbleness to might
And wealth and fame Boldly thy knife
To ailing women gave new life
With lion's heart challenging fate
The pelvic surgeon didst create

Dry teaching didst enliven and beguile
With Ligaments and Tumours, and the while
Thy wit did echo and thy cockney quips
Delightedly from students' lips

Wand'ring Elysian fields tonight
With Jockie Hunter kindred spright
And purring Tim with beady eyes,
Affection blended with surprise

The man we loved—remote and rare
A London sparrow in the air

W. R. BETT

Letters to the Editor

DEALING WITH DISASTER

SIR,—You do a much required service in drawing attention to the need for adequate arrangements for dealing with disasters[1] But surely you are wrong in stating that there are few areas in the United Kingdom not within easy reach of big hospitals? Reference to any railway map and to reports of aircraft accidents will show how wrong you are

In spite of the last sentence in your article of Feb 5, your antagonistic attitude to resuscitation on the spot has two serious dangers. First, you may prejudice inexperienced practitioners against resuscitation before evacuation Second, you may well be quoted (or misquoted) by lay administrators and committee members as an authority against making adequate provision for resuscitation at the scene of disasters

The indications for transfusion &c, before evacuation can only be judged by the medical man treating the patient, with due regard to the patient's injuries and condition and to the time and methods involved in evacuation Rather than your lukewarm final sentence you should write 'Arrangements for immediate transfusion *must* be included in the plan they may not be needed but when they are they will then save life '

MENTAL NURSING ANALYSED

SIR,—In your leading article of April 9 you discuss the study of the function and training of mental nurses carried out at the Bethlem Royal and Maudsley Hospitals in 1951–52

Among other points you draw attention to the discrepancy between theory taught and practical work done by student nurses in mental hospitals, particularly in their first year

This is an old problem which has been relieved a little by a new syllabus which contains the importance of mental and physical health to the individual the family and the community under the broad heading personal and communal health The preliminary syllabus however is still concerned mainly with the care of physical conditions and is therefore inappropriate for mental nurses. This is because it is assumed that the care of the sick in body is basic nursing while the care of the sick in mind is not and that basic nursing should be learned before something which is thought of as specialised Another reason is that the practice of teaching the preliminary syllabus in the first year (to allow students to take the examination as soon as possible) has hardened into tradition Most mental nurses and their tutors do not agree either with the assumptions or the practice but they accept the tradition bad as it is because the preliminary training school does allow an uninterrupted period in which to teach the preliminary subjects—an opportunity which for most tutors does not recur

There is a simple way out—namely a change in the order in which the syllabus is taken The purpose of the preliminary training school is to prepare a nurse for her work in the wards. The minimum period required is 8 weeks, some part of each day being spent in the wards These weeks should be spent in teaching mental nursing understanding and managing patients, and ward routines and practices. During the following 9 to 12 months psychiatry and mental nursing should be taught The subjects in the preliminary syllabus with their bias towards physical nursing could be taught in the second year together with the medical and surgical nursing usually taught at this time The preliminary examination could be taken at the end of the *second year* when the students would have the knowledge and practice and therefore the confidence to pass The only stipulation the General Nursing Council makes is that the preliminary examination shall be taken before the final. The third year should be occupied by advanced psychiatric nursing and before taking the final examination a short revision of the nursing of physically ill patients

[2] Dare D., Hank, et Pierre *Eagle* July 1950

[1] *Lancet* 1954 i 1003; *Ibid* Feb 5 1955 p 205

The conflict between the needs of the hospital for service and of the student for education is another old problem, one solution to which is suggested by reading the Bethlem and Maudsley study

This compares two ways of arranging nurses' hours in mental hospitals—the so called long day and the shift system The long day is said to need fewer staff but it is very tiring for the nurses The shift system may need more staff but it can be arranged with overlapping time which could be used by students for lectures and private study It would be possible to have the best of both systems by letting the trained, auxiliary, and part time staff work the long day (or night), and the students work overlapping shifts This would allow the wards to be staffed by those not in training at the times when the students' shifts overlapped, and it would allow the students to have some part of every day for study

These simple changes could remove two of the greatest difficulties in the training of mental nurses and help to smooth the furrows from the tutors' brows

R M N

PHARMACOLOGY OF RESERPINE

SIR,—Oversimplification of complex problems by postulation is an old philosophical method which despite its age is unacceptable in science Your leading article of March 12 contained a striking example You postulated that reserpine was "the active alkaloid" of *Rauwolfia serpentina*, and then felt free to treat all data accumulated on any rauwolfia medication as if they had been obtained by using reserpine

1 Actually there are at least five generically different preparations of rauwolfia

(*a*) Ground rauwolfia root containing reserpine like (brady cardia, hypotension, sedation producing), yohimbine like, and numerous other alkaloids possibly potent in as yet unassessed desirable or undesirable ways The fact that ground crude root preparations can be made from any of more than one hundred varieties of rauwolfia from all over the world (varieties which have manifestly different constituents), and the fact that even within the most desired species (*Rauwolfia serpentina*) there exist differences between roots from Siam, Burma, Thailand, and India, make lumping of data hazardous There are rauwolfias which apparently contain no reserpine (*Rauwolfia paraensis*, *Rauwolfia cambodiana*, and *Rauwolfia caffra*)

(*b*) The alseroxylon fraction, 'Rauwiloid,' an alkaloidal extract known to be free of yohimbine like alkaloids, known to contain reserpine, rescinnamine, and other potent reserpine-like materials, guaranteed by its manufacturer to be made only from *Rauwolfia serpentina* of Indian origin

(*c*) Reserpine, a single alkaloid, difficult to purify, extracted from any of *Rauwolfia heterophylla* (South American), *Rauwolfia hirsuta* (South American), *Rauwolfia vomitoria* (West Africa), *Rauwolfia canescens* (India), *Rauwolfia serpentina* (India) The contaminant alkaloids vary with the root of origin, and the difficulty of being sure that the sample is over 80% reserpine varies also This alkaloid does not produce adrenergic blockade at any dose It is the tri methoxy benzoic ester of methyl reserpate

(*d*) Rescinnamine, a single alkaloid whose structure is thought to be the tri methoxy cinnamic ester of methyl reserpate, found to date only in *Rauwolfia serpentina* While rescinnamine is not presently available for purchase, a considerable clinical usage has revealed that it is distinctly less sedative than reserpine, though pharmacologically both quantitatively and by its general potency, it is reserpine like

(*e*) Canescine, isolated from *Rauwolfia canescens*, is probably 11 desmethoxy reserpine Animal work has established that canescine is a member of the reserpine group, but clinical experience is not wide enough as yet to permit any guess as to its properties as applied to human disease

2 Present clinical indications suggest that the mixed alkaloids without the yohimbine component (*b* above) present a better balanced action less critical in dosage and somewhat less threatened with side actions Only further clinical work will establish this and elucidate reasons for it

Examination of the references cited in your lea article will show that numbers 1, 2, 4, 5, 6, 25, and were concerned with preparation (*a*), 6, 8, 10, 21, and were concerned with preparation (*b*), and the rest with preparation (*c*) Few papers exist on (*d*) and (*e*)[35-41]

Meanwhile, oversimplification of the situation by postulating that reserpine is clinically and pharmacologically typical of all rauwolfia preparations can only interfere with proper stimulation of investigators to clarify further the enigmas involved

References 1–34 are contained in the leading article (March 12, 1955, p 548)

Los Angeles, California, U S A GEORGE L MAISON

⁂ Dr Maison earns our thanks for his valuable survey of rauwolfia preparations In our leading article we tried to resolve confusion caused by the introduction of different rauwolfia preparations, and in referring briefly t the clinical use of rauwolfia we did not distinguish between experience with different preparations, but, in fact, all but three of the papers cited on the experimental pharmacology of reserpine, with which we were principally concerned, dealt with pure preparations of the alkaloid —ED L

GENETIC EFFECTS OF THERMONUCLEAR EXPLOSIONS

SIR,—Biologists tell us that mutations followed by selection have been the chief factors in improving living species Yet in current discussion of the genetic effects of radiation, it is widely assumed that any increase in the human mutation rate must be harmful to the species Are we to infer that for mankind alone selection is impossible? Or is the human race already so perfect that further improvement is inconceivable?

The public have had ample warning of harmful mutants Should not equal stress be laid on the relatively rare favourable mutations which could be of great benefit to the race?

Wendover R B BOURDILLON

REGISTRARS AND REGISTRARS

SIR,—At present some medical registrars are quite obviously to be considered solely as trainees There is, for example, the professorial unit type, who assists in the investigations and treatment of a handful of patients with obscure maladies, aided by six or so colleagues of similar status, and adequately supervised by his eminent chiefs He will have much spare time in which to browse in the university library or spend in learned discussion From time to time he may take part in the preparation of articles of high academic merit for learned journals

Other registrars find themselves so busy with the day chores that academic achievement is out of the question Consider, for instance, the lot of the average registrar at a provincial chest clinic, who shares clinic sessions and domiciliary visits equally with his consultant chest physician and the S H M O, and who deputises for the radiographer, clerk, or health visitor as occasion requires Indeed, what is meant to be the proper function of the grade has been the subject of much recent controversy

Clearly the current title of registrar covers no more a homogeneous group of appointments than does, say, the military rank of staff captain It is worth noting however that the latter designation is rarely used by itself—a letter is usually suffixed in parenthesis to show more exactly the duties of the gentleman in question

---

35 Cronheim G, et al *Proc Soc exp Biol N Y* 1954, 86 1
36 Cronheim G, Toekes, I M *J Pharmacol* 1955 113 13

41 Cronheim, G, Orcutt, J, Toekes, I M Unpublished

Thus an officer in the intelligence branch would be labelled staff-captain (I) and the corresponding one in the medical department staff-captain (M)

It is suggested to the Strachan Committee that they now recommend two subgrades of registrar those who work strenuously at peripheral hospitals to be known as working registrars or registrars (W), and those who train leisurely at the teaching hospitals to be labelled registrars (T)

REGISTRAR (W PLUS)

CLONAL AGEING AND CANCER

SIR,—Your leader of March 26 which I found most interesting suggested to me a possible explanation for something which has always puzzled me—namely how it is that carcinogenic agents such as cigarette smoke need to act for many years before their effects appear

If the carcinogen acted directly upon the cell nucleus or cell protein it should like other poisons act at once If, on the other hand its action depended (like radiation) upon some statistical chance of reaching the cell nucleus, then some persons would be affected early and others late in a continuous series

But if the carcinogen simply acts by causing cells to proliferate so that instead of dividing by mitosis x times in 20 years, they have been stimulated to divide $x \times y$ times ($y > 1$) and if, as Sonneborn seems to have shown in paramecium, the chromosomal substance duplicates more and more inaccurately as the number of divisions is increased and if this kind of nuclear aberration could cause a malignant change in the cell the reason for the latent period would be explained.

I write in complete ignorance as to whether there could be anything in this theory in the hope that some more knowledgeable reader will enlighten me Perhaps the effect of carcinogens on cell multiplication is already well known but when I recently asked a well known expert in cancer research the cause of the latent period in the action of carcinogens he was unable to give me an explanation

Manchester ROBERT PLATT

ENURESIS

SIR—In your leading article of Feb 19 you emphasise again the importance of considering all factors bearing on this elusive but widespread syndrome There can be few who would not agree that each case must be studied as an individual problem or that in most cases there would seem on investigation to be multiple ætiological factors I would however draw attention to one or two observations made elsewhere

In considering the establishment of a simple conditioned reflex Crosby[1] describes a method which aims at extinguishing any conditioned responses which facilitate micturition and at reinforcing the natural method of building up inhibitory tone

Discussing the use of the amphetamine drugs you mention the lightening of sleep but do not discuss the possibility that the action may involve 'alerting' of the cerebral cortex via the reticular diffusion system[2] and that such action need not proceed to arousal but can yet activate cortical reception and the intensity of the subsequent inhibition impulse[3]

In considering the phenomenon of nocturnal enuresis the concept of delayed or inept cerebral adaptation[4,5] should perhaps be borne in mind.

RADIOLOGY IN THE MANAGEMENT OF ANTERIOR PLACENTA PRÆVIA

SIR,—Mr Russell and Dr Warrick in their commendable article last week do well to emphasise the potential dangers to the fœtus from cæsarean section in the anterior type of placenta prævia and in pointing out how the extra information gained from soft tissue placentography may be used in making the operation safer for the fœtus

I am sure however, that they can make the operation safer still for both fœtus and mother by avoiding examination under anæsthesia altogether when there is such good evidence (both radiological and clinical) of major placenta prævia, and proceeding to cæsarean section without it In this way the patient will not be made to run the extra risk of serious bleeding caused by percervical examination; the fœtus too, will not be subjected to anæsthesia for longer than is necessary

When precise soft-tissue placentography and the clinical findings both point to a major degree of placenta prævia, not only is there no need to use the hazardous digital examination of the lower segment but there is every reason for avoiding it This is only one of the important contributions that soft-tissue placentography has made to the management of placenta prævia

The London Hospital E 1 ROBERT PERCIVAL.

COWPOX IN MAN

SIR,—The paper by Dr Bernard Laurance (April 9) provides a timely reminder about the wealth of material still awaiting investigation in the sphere of comparative medicine—the comparative medicine near at hand in everyday life In the outbreak he describes there are implications involving medicine surgery pathology, and epidemiology, any one of which subjects could well provide a matter for separate study, while such outbreaks seem to present special opportunities for further studies on viruses

I suppose there are so few references in the literature

RUPTURE OF THE DUODENAL STUMP AFTER GASTRECTOMY

SIR,—I would like to give strong support to the contention by Mr Henson in his article of March 19 In my experience this complication has twice followed obstruction to the afferent loop and there is little doubt in my mind that, except in the cases where closure is frankly inadequate, this is the usual sequence of events That the complication may occur is, among other reasons, a good one for avoiding the Polya operation in gastric ulcer wherever possible

In duodenal ulcer, where the operation has its main use, the technique which avoids the use of occluding clamps of the Lane type is the surest and safest way of making an anastomosis unlikely to produce obstruction A full-width anastomosis can be used with little risk of contamination or bleeding if the stomach is divided with high frequency diathermy, provided preparation has been good beforehand

There is little risk of contaminating the peritoneal cavity if the Finsterer type of operation is preferred, The lesser curve part of the stomach can easily be closed using the Maingot clamp, and an anastomosis carried out without the use of any further clamps

In my experience any contamination that may result is negligible and it is possible for the less experienced surgeon to ensure a safe stoma and hence a safe duodenal stump

Kimberley, British Columbia C R NEVE

CONTINUOUS INTRAMUSCULAR OXYTOCIN

SIR,—Continuous intravenous oxytocin has been shown to be a powerful therapeutic weapon in many obstetric problems demanding stimulation of the uterus By carefully regulating the rate of administration, an optimal uterine response can be obtained and normal progressive labour effected [1]

The presence of an intravenous needle, however, is not without its disadvantages Variations in the position of the needle relative to the heart will influence the rate of flow, movement of the arm may compress the vein or occlude the end of the needle and this can only be overcome by splinting, trauma to the vein wall and the prolonged administration of isotonic solutions, especially glucose, often result in local thrombosis, and, because the patient is immobilised and her arm is splinted, her morale falls should it be necessary to continue the intravenous drip for more than nine hours To avoid these disadvantages oxytocin given by continuous intramuscular drip was tried and has been found to be highly satisfactory

10–15 units of oxytocin is added to 1 pint of normal saline solution The needle of a standard intravenous giving set is replaced by a no 12 intramuscular needle, which is then inserted under strict aseptic precautions deep to the ilio tibial tract into the vastus lateralis muscle in the middle third of the thigh 1000 Benger units (450 turbidity reducing units) of hyaluronidase dissolved in 1 ml of normal saline solution is injected into the rubber tubing near the needle The drip is then begun at 5 drops per min and thereafter the rate of administration is slowed or increased until the desired response is obtained The relatively high concentration of oxytocin used reduces to a minimum the amount of saline given, and since there is no danger of thrombosis very slow drip rates are practicable The standard intravenous clip lacks sensitivity of control, and that recently described by Waller [2] has proved invaluable and greatly facilitates the initial regulation of the drip

The average case has required approximately 0 2 unit of oxytocin per hour, which is the same as by the intravenous route, and although the rapidity of response is slightly reduced this is not sufficient to influence either the control or safety of the method The hyaluronidase is effective for at least six hours, but it has been the custom to inject a further 1000 Benger units into the rubber tubing every four hours and ensures a constant rate of flow

The patient is allowed to sit up and is encouraged to herself usefully with knitting, neither of which is p with an intravenous needle

As with the intravenous route, continuous intra muscular oxytocin has been found particularly us in cases of failed surgical induction and hypoto inertia, and as a means of inducing labour with the not engaged in the pelvic brim It must be emphas that hypertonic uterine inertia associated with distress colicky pains and cervical achalasia, and major ceph pelvic disproportion are both an absolute contra indication to oxytocin therapy

Hyaluronidase in therapeutic doses is non toxic, a no adverse local reactions have been observed.

Guy's Hospital,
London, S E 1 J M HOLMES

PEPTIC ULCERATION IN SOUTHERN NIGERIA

SIR,—I have read with great interest the lette relating to my paper (Nov 20) from Dr Buxton (Dec 11 Dr Watson Smith (Jan 1), and Mr Rose (Jan 8)

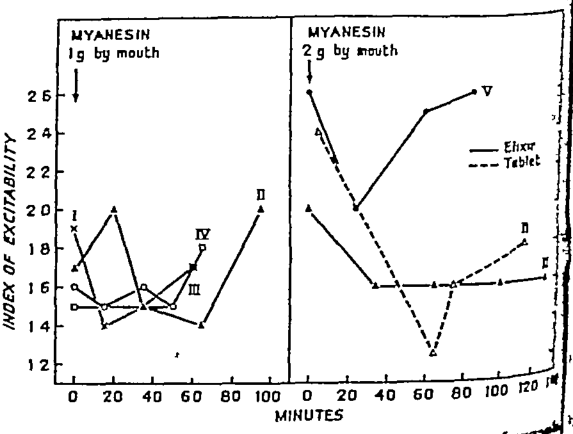
As to the psychosomatic aspect, other conditio thought to develop on this basis, such as thyrotoxicos coronary thrombosis, and ulcerative colitis, are qu uncommon in Southern Nigeria I agree that " the exa mation of physiological fluids is child's play compared wi the intricacies of the psychosomatic side " The poi however, is that though we all appreciate these intricac their study has not helped to solve the ulcer proble Peptic ulceration in Southern Nigeria is a distinct patho logical entity occurring in an area with well def climatic and agricultural features, and it may well that measuring physiological fluids and other substan will shed a little light on certain aspects of the probl

To Mr Rose I would reply that in Southern Nig heavy infestation with hæmatobium is not comm found, whereas infestation with other helminths, nota ascaris and to a lesser extent ankylostoma, is comm We have examined several specimens of duodenal ul to exclude hookworm as an ætiological factor, and such relationship could be established

University College,
Ibadan, Nigeria P G KONSTA

EFFECT OF MEPHENESIN ON MUSCLE EXCITABILITY

SIR—During a pilot study of neuromuscular exci bility in man (to be published) I noted an appar increase in excitability following therapeutic doses 'Myanesin' (mephenesin) Owing to certain pract difficulties this investigation was not completed, and I therefore prompted to record the initial results in t hope that others will confirm or disprove them



Changes in muscle excitability after oral administration of my

The excitability of the abductor pollicis brevis of five niversity students was measured with a Ritchie Sneath onstant voltage stimulator before and after the oral dministration of myanesin in 1 g and 2 g doses The onditions of the experiment were rigidly controlled (as ill be described elsewhere) The index of excitability dopted was the ratio between the minimal voltage equired to produce a contraction at 0 01 milli-sec ulse-length and the rheobase (i.e the smaller the index, he greater the excitability)

The accompanying figure shows that in all but one ase there was an increase in excitability shortly after ngestion of the myanesin.

Bromley Kent. DAVID M ZAUSMER.

CONGENITALLY SHORT FRENULA OF UPPER LIP AND TONGUE

SIR,—The gap between the permanent upper central ncisors, referred to by Mr Oldfield in his article of March 12, is of interest to dentists and orthodontists. Some years ago, the teaching was to remove the frenulum and perhaps some of the bone when these two teeth were separated There is abundant evidence in the form of serial models to show that it is normal for them to be separated at the time of eruption and that later they come ogether naturally but there are cases in which this does not occur

Radiographs disclose a difference in the appearance of the bone of the maxillary suture between these teeth In the normal case the suture terminates in two distinct Vs of compact bone, each enclosing cancellous bone In he other case the appearance is variable: the Vs are ot to be seen and the bone between the teeth appears o be cancellous, having a more or less square end. After emoval of the frenulum and perhaps some of the bone, n such cases and artificially bringing the teeth together elapse has followed removal of the appliance

The same bone condition may be seen in the deciduous entition, and I suspect this will be followed by permanent eparation of the upper permanent centrals

It is normal for deciduous centrals to be separated on ruption and during their life and for the attachment of he frenulum to migrate from a point near the alveolar dge to one higher in the sulcus there may be a very mall proportion of cases in which this does not occur nd in them it may be a factor in keeping the centrals part

London, W 1 HAROLD CHAPMAN

SIR,—The pendulum has swung rather far if it has led o the assertion that there is no such thing as a short renum Almost every speech defect has been ascribed o tongue tie even stammering but defects of rticulation are much more commonly due to hearing efects neuromuscular abnormalities emotional imma urity and lack of intelligence Even a glossectomised atient can speak intelligibly and speech can be normal n spite of short frena linguæ I have seen two young eople with this condition who were training for the tage and who were able to reach the required standard f clarity of diction Certainly there are such things as hort frena, but they are rarely the cause of speech efects

I have seen patients whose defective articulation was hought to be due to tongue tie a phonetic test showed they ere able to pronounce words with t d l n (the lingua-alveolar ounds) in fact they were using these sounds instead of k g nd ng in their dyslalic speech!

In 1935 I compared 180 children undergoing orthodontic reatment with 30 controls examined by the orthodontist and assed as having no dental irregularities and another 20 hosen at random. The aim was to ascertain the relationship etween faults of dentition and defective articulation I ound no significant correlation; but among the controls there as one girl with a short tongue frenum whose speech was normal and free even from minor errors found in others with normal frena and normal dentition.

Where short lingual frenum and high palatal arch are found together speech is more likely to be defective Intelligent, emotionally stable healthy people can over come a slight physical handicap without operation or speech therapy

London, N W 11 JOAN H VAN THAL.

TUBERCULOSIS IN IMMIGRANTS

SIR —We would like to reply to some further points raised by Dr James (April 9)

First that we believe without having carried out a single preliminary test that it is the tuberculin negative Irish who develop disease in England This bare state ment may reflect Dr James's interpretation of our point of view, but this is what we said

> 'From a third to a half of Irish immigrants aged 15–25 *from rural areas* are estimated to be non reactors to tuberculin. It is suspected that most of the Irish patients especially females, who later develop tuberculosis, are recruited from this group A smaller proportion break down as a result of progression or recrudescence of infection received before *leaving home*

So far as we are aware no evidence has yet been presented to refute this statement, on the contrary the report of the National Tuberculosis Survey in Ireland produces factual evidence which is entirely in keeping and Flynn and Joyce have suggested that we have underestimated the extent of the problem The conclusions reached in both publications were similar to our own

> The point regarding the lack of preliminary tuberculin tests was not in our power to rectify as the investigation was conducted on hospital patients already diagnosed we related our findings in those patients to those of other investigators whom we deem reliable, who had produced evidence regarding the high rate of tuberculin negativity in rural Ireland and we made deductions therefrom which appeared to us reasonable Even so we stated that the facts that we have collected are objective data but the interpretations we have made may not be correct and some are necessarily speculative; more evidence and much hard thinking are still required" We are prepared to accept legitimate correction of our viewpoint on evidence supported by facts, but polemical statements cannot be accepted as evidence

Secondly Dr James's statement that the idea that tuberculosis arrived here recently is quite fantastic it was recorded as a cause of death in Irish cities in the 17th century and I have no doubt it was known much earlier This crushing broadside merely indicates once more that Dr James has not made sure of his target before pulling the trigger Our statement reads: 'Ireland did not experience the *peak* of its epidemic wave until much later than England Ireland is now at a stage of development passed by England some considerable time ago and it is to this fact rather than to any racial' weakness in the Irish that the higher proportion of susceptibles is due We were also at some pains to point out that it was the *rural* Irish to whom our argument mainly applied and that migration of such susceptibles to cities where infection is much more likely to occur is important in the epidemiology of tuber culosis Dr James believes that those already infected are responsible for the high incidence in immigrants What does he think happens to the tuberculin negative? Do they stay at home successfully avoid infection after arriving in cities or invariably overcome it when it occurs? They must do one of these things if they do not provide the raw material for many of the cases we see

The point about the Irish famine and tuberculosis is a more serious one Disastrous and widespread as it was its effects cannot be considered identical with those of the sustained, centuries-old, endemic infection in cities

The Irish report recognises this when it indicates that the death rate increased again after an interval "when a new generation presented a sufficiency of pabulum" *Natural* resistance we believe is of fundamental importance in determining the course of tuberculous infection, even the point regarding Mantoux negativity or positivity on arrival in Britain is of lesser import, for the place where infection occurs has little bearing on the subsequent course of the disease

Dr James insists that "the intensity of infection in any country is the decisive factor in causing tuberculosis, and that the eradication of tuberculosis is not made easier by those who point out spurious short cuts upon which to waste energy and resources" If this mighty blow is intended for us we would refer him to the concluding sentence in our article "This suggestion [for B C G immunisation of immigrants before leaving home] does not imply any relaxation in other measures at present being applied to combat or prevent tuberculosis It is in no sense a substitute for good nutrition, improved housing, or adequate treatment of the infectious patient" We also proposed that "in addition to vaccination before the immigrants leave Ireland, a follow up would be desirable in this country to detect reverters, to re vaccinate where necessary, and to control the health of immigrants by routine radiography Effort, organisation, and coöperation would be required from authorities on both sides of the Irish Sea, but there is the prospect of a considerable alleviation of human suffering and misery, and probably of a considerable reduction in public-health expenditure, for tuberculosis is a costly disease"

We regard the supervision of the health of immigrants as vitally important It implies routine tuberculin testing in Ireland beforehand—a measure which in itself, according to the Irish report, leads to more efficient detection of the unknown sputum-positive person—and should help to discover potential sources of infection in Britain at an early stage, if this is a "spurious short-cut" it seems to us one which is remarkably difficult to accomplish

Regarding the efficacy of B C G vaccination in preventing pulmonary tuberculosis, we retain an open mind That it is a complete answer we do not claim, we do suggest it should be tried If Dr James disagrees we should be grateful if he would state his reasons

The whole subject of immigration and tuberculosis is beset with quite extraordinary difficulty, further investigation is important and *facts* are required If Dr James wishes to substantiate his statement that those already infected are responsible for the high incidence in immigrants, either by progression of the infection or by "reinfection," it would benefit his case enormously were he to produce evidence to this effect Until such evidence is forthcoming we must adhere to the point of view we now hold

NORMAN MACDONALD
EVELYN V HESS

THE CLOUDED CRYSTAL BALL

SIR,—I cannot resist expressing my concern for poor old Whiddon's nephew (April 16, p 811), partly, of course, because I simply must do something with the leisure afforded me by our technical staff Since, no doubt, this young man holds Harry Hawke in the highest esteem, it is likely that he will come to believe earlier than usual in his career that there necessarily must be some irremediable taboo between bed and bench Later on, poor chap he may feel himself to be half a physician and indeed he might even become a specialist in diseases of the blood and then, oh dear, what confusion What is a hæmatologist ? Is he to be defined as a scientist who , a physician who a bleeder who ?

I do hope that Uncle Whiddon will convince his nephew that whether at bed, bench, or X ray table, he could still be a *doctor*

Upton, near Newark Notts

A B HILL

VACCINE LYMPH AND AUREOMYCIN

SIR,—The death of the Australian children received diphtheria-prophylactic supplied in large c tainers, referred to in your annotation of March 5, not due primarily to the large containers, as you sugg but to the fact that the material was supplied in co tainers holding more than one dose, *to which no antis had been added* The Therapeutic Substances Regulatio of 1931 and of 1952 require that "when any therapeuti substance is issued in liquid form in containers which are sealed in such a manner that portions of the contents can be withdrawn for use on different occasions, the liquid shall contain a sufficient proportion of some bacterio static to prevent the growth of any organism which may be introduced in the process of removing a portion of the contents of the container"

I think the distinction is important, because the use of multi dose containers is not objectionable, provided a effective bacteriostatic is present

A E FRANCIS

HARDENED FATS AND LUNG CANCER

SIR,—Dr Bender (Feb 12) has drawn attention to the content of essential fatty acids (E F.A) in samples of American margarine oils and butter

The reference to the paper in question[1] is not compl without mentioning that hydrogenated coconut-oil w found to contain no linoleic acid and no arachidonic acid and that bioassay methods showed that some margarine oils contained 2 4–6 8% linoleic acid and the much-used "selective" hydrogenated oils 0 9–3 0% linoleic acid. No of them contained arachidonic acid, and non winter cottonseed oil (not hydrogenated) contained 42–48% lino acid Long stability shortenings have great resistance to oxidation through virtual elimination of the polyunsatur fatty acids, including the E F.A Butter contains 3 2–4 linoleic acid and 0 2% arachidonic acid having a biopote 6 2 times that of linoleic acid when fed in mixture w linoleic acid to fat-deficient rats[2] As to "selective" hyd genation, the aim is not to saturate all double bonds of fat but to be satisfied with the conversion of linoleic acid linolenic acid to oleic acid How well this destruction of E.F can be completed is clearly demonstrated

In the United States margarine changed during the 191 period from a product manufactured mainly from ani fats to one in which coconut oil, and later cottonseed and soybean oil, predominated The American marga and shortening industry has therefore had to depend more more on the E.F.A reducing hydrogenation processes Ameri margarine can be made without or with some linoleic a but does not contain the valuable arachidonic acid. can therefore easily be responsible for low dietary intake E.F A.

In the United Kingdom in 1946 cottonseed and soyb oil were very scarce, coconut, groundnut, palm kernel, marine oils were the main raw materials The risk of a E F.A diet is thus possible

An idea of the human requirement of E F.A can be obta from the fact that human milk fat contains 9 1% E.F. representing 13 3 per 2500 calories of the milk For ad the requirement will be less

Food consumed domestically in the U.K (1952) cont about 3 5 g linoleic acid per 2500 calories, equal to 3 4 g p head per day An estimate based on Drummond's[4] midd class diet (1939) gives 4 2 g per 2500 calories and 5 5 g p head per day If these diets are representative the aver consumption of linoleic acid fell between 1930 and 19 from about 5 to 3 g per head per day The consumption arachidonic acid fell at the same time from 0 8 to 0 3 g

---

1 Deuel, H J jun Greenberg S M, Anisfeld L, Melnick, J Nutr 1951 45 535
2 Greenberg S M Calbert, C E, Deuel, H J jun, Brown, *Ibid* p 521
3 Standard Values in Nutrition and Metabolism Edited E C Albriton Philadelphia 1954 p 111
4 Drummond J C Wilbraham A The Englishman's Fo London 1939, p 565

With a decrease in an already low E.F.A. diet the risk that more and more people receive less than their optimal requirements will grow considerably. (The present incidence of lung cancer requires only that the lungs of less than 1% of the population are rendered more vulnerable to cancer-producing substances by a defect in a defence mechanism.)

10 g. more lard would increase the intake of linoleic acid by more than 0·8 g.; and of arachidonic acid by about 0·1 g. 10 g. olive-oil gives 0·8 g., 10 g. groundnut-oil 2 g., and 10 g. corn-oil 4 g. linoleic acid. People living in regions where, for instance, the diet is rich in lard (pork) or olive or groundnut or corn oil (whole corn) will thus easily receive a diet rich in E.F.A., even on a low-fat diet, which can also be an advantage. Overweight individuals are more liable to develop cancer than average or underweight, and long-term caloric restriction tends to suppress tumour formation in mice.[3]

Your annotation of Feb. 19 on cancer clues, Professor Banks's letter of March 5, and the differences in incidence of lung cancer between different regions where the diet may easily vary in E.F.A. content strengthen the view that other ætiological factors than smoking should be investigated.

Copenhagen. JOHAN E. NYROP

POSTOPERATIVE MEMBRANOUS TRACHEOBRONCHITIS

SIR,—We were much interested in the article by Mr. Dark and Mr. Jewsbury in your issue of Feb. 26, for we have recently seen a case which, we think, is very similar to those they describe.

A man of 19 attempted to commit suicide by taking a barbiturate. He came into hospital deeply comatose, and bronchoscopy was performed because he had aspirated vomit. After bronchoscopy breathing was still laboured and a no. 9 cuffed Magill tube was passed and left in place for about eighteen hours.

Three days later, after the patient had recovered consciousness, he noticed in his sputum a membranous cylinder about 5 cm. long and moulded perfectly by the trachea. The patient recovered and a further bronchoscopy was not thought necessary.

Microscopic examination of the cylinder showed clotted blood, fibrinous material, and polymorphs, with no evidence of mucosal elements—findings similar to those reported by Mr. Dark and Mr. Jewsbury.

1st Surgical Clinic and 2nd Medical Clinic, Hospital Escolar de St. Marta, Lisbon. ANTONIO COITO ANGELO FLORA

HYPOTENSION TREATED WITH CONTINUOUS NORADRENALINE

SIR,—The following case may be of interest to your readers.

A healthy active old man of 89 fell and broke his leg on Sept. 29. X-ray examination revealed a subtrochanteric fracture of the left femur with moderate displacement. His leg was put up on skeletal traction and a Thomas's splint. His general condition was good.

On Nov. 13 there was no evidence of callus at the fracture site, and on Nov. 19 an open reduction with plating of the femur was performed under general anæsthesia. About a pint of blood was lost, and during the operation the patient became very shocked with, at times, an almost unrecordable blood-pressure. 3 pints of blood was given in the theatre. Five hours later the systolic pressure was 70 mm. Hg and could not be raised by any of the usual anti-shock methods. The patient was still unconscious.

Eight hours after the operation an intravenous drip of normal saline solution containing *l*-noradrenaline (‘Levophed’, 4 mg. per litre) was started at the rate of 2 ml. per min. Within five minutes the blood-pressure was 100/100 and the patient had regained consciousness. The blood-pressure was maintained at 130/90 by running the drip at about 1·5 ml. per min.

During the next sixty hours it became possible to slow down the drip, but on completely stopping it the systolic pressure fell to 70 or less, and it was not until the end of this time that the patient became able to maintain his blood-pressure at 130/80 by normal reflex mechanisms.

He subsequently recovered to a very large extent, eating and drinking normally, but extensive sacral sores developed under the plaster spica, and the resulting toxæmia led to his death on Dec. 25.

The severe and persistent hypotension was probably due to adrenal exhaustion. In view of the relatively high cost and scarcity of adrenal cortical extracts, *l*-noradrenaline seems to be a useful substitute in some circumstances.

My thanks are due to Mr. N. Ross Smith and Dr. R. D. Scott for permission to publish this case.

Boscombe, Hants. M. V. GUILMANT

THE HAIR OF THE PILONIDAL SINUS

SIR,—I know of two apparently typical ‘pilonidal’ sinuses in the natal cleft which contained instead of hair pieces of grass. In these interesting cases the sinuses were originally lined with turf. The turf, having shed the piece of grass, was then destroyed by granulation tissue so that it was not found in the operation specimen; but one knows that turf must have been there originally by analogy with the much more common hair-containing sinuses which are originally lined with hair-bearing skin.

Or perhaps Mr. Weale (*Lancet*, April 16) and the endogenists are wrong, and the reason why one does not find a grass-bearing (or hair-bearing) lining is that there never was one and the grass (or hair) gets in from the outside.

London, W.1. B. H. PAGE

PITUITARY STIMULATION OF ERYTHROBLASTIC MITOSES IN BONE-MARROW

SIR,—In the course of investigations into the influence of the pituitary on erythropoiesis we have found that the pituitary plays an important part in erythroblastic mitoses in bone-marrow.

The reproductive activity of the myeloid cells has been estimated by the stathmokinetic test, using colchicine. It is well known that, in any type of tissue, the number of mitoses blocked by colchicine in a certain time is related to the proliferative activity of the cells.

Using this technique 10 normal rats were injected with colchicine (1·75 mg. per kg.). Nine hours later 71·1%±14·8% of the basophilic erythroblasts, and 56·8%±12·8% of the polychromatophilic erythroblasts in the bone-marrow were in mitosis (stathmokinesis). On the other hand fewer granuloblastic mitoses were blocked: 31·4%±0·3% in myeloblasts and 2·8%±1·5% in myelocytes.

In 10 hypophysectomised rats, of the same strain, age, and sex, ten days after the hypophysectomy, the colchicine blocked 26·2%±13·1% mitoses in 100 basophilic erythroblasts, and 15·8%±14·6% mitoses in 100 polychromatophilic erythroblasts. But no great difference was found between the proportion of mitoses blocked in the granuloblasts of the hypophysectomised and of the normal rats.

The reduction of the reproductive power of erythroblasts after hypophysectomy is followed by the well-known reduction of reticulocytes in bone-marrow and in blood, by intense medullary erythroblastic hypoplasia, and later by anæmia.

Hypophysectomy, however, does not modify the mitotic rhythm of granuloblasts and *does not reduce the granuloblastic quota of the bone-marrow*. Therefore *the so-called pituitary regulation of erythropoiesis seems to be based on a regular and selective pituitary stimulation of the mitotic rhythm of the medullary erythroblasts.*

Obituary

EVELYN CHARLES SPRAWSON

M C, D Sc, Lond, M R C S, F D S

As professor of dental surgery and pathology at the London Hospital, and as chairman of the board of studies in dentistry of the University of London, Evelyn Sprawson was one of those who did most to raise the general level of dental education and research in this country

Born in 1881, he was educated at King's College School, London, and began his dental studies at the Royal Dental Hospital, where he won the Walker and Saunders scholarships After taking the L D S in 1902, he continued his medical studies at Charing Cross Hospital and gained the Conjoint qualification in 1905 Having set up in practice in Cavendish Square, he joined the staff of the City of London Hospital for Diseases of the Chest, and became assistant dental surgeon and lecturer in histology at the National Dental Hospital When the London Hospital Dental School was formed in 1911 he joined the honorary staff But his work there was interrupted by the outbreak of war He served as a captain in the R A M C and was mentioned in despatches and awarded the Military Cross for his gallantry in action

On his return in 1919 he retired from private practice and was appointed the first director of dental studies at the London Hospital Thenceforward he gave all his time to teaching and research, and he published papers on a wide range of subjects in dental histology and pathology, including his important studies on dental enamel, odontomes, abnormalities in dental structure, and the effect of diet on tooth formation His work at Dr Barnardo's Homes, to which he was dental surgeon from 1908 to 1953, gave him unusual opportunities for controlled clinical observation F N D recalls that

> "the first result of these studies was his papers on the percentage of organic matter in human tooth enamel, for this thesis based on this investigation, he was awarded the degree of D SC by the University of London He then turned his attention to the relative effects of raw and pasteurised milk in promoting adequate calcification in teeth, he believed that raw milk contained an activating agent which was inhibited in pasteurised milk The statistics which he based on his continual observations of children in Barnardo's Homes were carefully prepared and deserve more consideration than they have yet received "

He received the Tomes prize of the Royal College of Surgeons for 1927–29 and was awarded a Hunterian professorship in 1936–37 He was associated with the late Sir Frank Colyer in the revision of several editions of *Dental Surgery and Pathology*, and "Colyer and Sprawson" remained for years the standard textbook on the subject He also edited the *British Dental Annual* in 1952

In 1940 Sprawson was appointed to the chair of dental surgery at the London Hospital He examined for the Universities of London, Birmingham, Durham, New Zealand, and Witwatersrand, for the Dental Board, and for the Royal College of Surgeons of England He was among the first to be elected to the college's fellowship in dental surgery, when this was started in 1947 In the same year he delivered the Charles Tomes lecture to the college As well as being chairman of the University Board of Studies in Dentistry, he was deputy chairman of the Dental Education Advisory Committee, and a vice-president of the International Association for Dental Research His work for these bodies reflected his interest in his specialty and in education, but he also offered his medical colleagues able and devoted service through the Medical Protection Society, of whose council he was a member for nearly 17 years "His quiet manner," E R C writes, "covered a shrewd and determined character his advice on medicolegal problems was invaluable" To another fellow member of the council he admitted that, of all the bodies on which he served, the meetings of the Medical Protection Society were those he most enjoyed He died at a meeting of the council on April 6, at work among his friends

To Sprawson, the man and colleague, F B B pays the following tribute

"Modest, unassuming, and gentle, and very much on the quiet side, Sprawson never spoke much about himself but always with great intensity about anything on which he was engaged, or which might be the subject of discussion or conversation He had many admirable characteristics, but to my mind the one that was most outstanding was the thoroughness with which he dealt with anything he undertook A notable example of this was an occasion when he had to give expert evidence for the defence in a case in which the mandible had been fractured during the extraction of a molar tooth. Realising that it might be difficult for the Judge to understand the technicalities of the case by mere verbal explanation, he took with him to the court a mandible and specimens of the instruments used When giving his evidence at the hearing, he produced them, and this so pleased the Judge that he invited Sprawson to the Bench, where he gave a first-rate demonstration of the operation He was keenly interested in numismatics, chiefly the coinage of the Hanoverian period, and he was often to be seen at Glendining's sales He was also a great gardener, and rarely missed the Horticultural Society's shows at Chelsea and Westminster It will be seen that he tended towards the quieter interests of life and apart from a little sporadic firing of a rifle, I never knew him to evince any interest in sport, outdoor or indoor of any kind Essentially studious, he always seemed happiest when attempting to elucidate some scientific problem. He was a lover of books, especially of biographies and of works on dental surgery, whether ancient or modern

"He had a quiet voice, and a somewhat halting delivery, and he often asked me whether he spoke loudly enough when talking at a meeting, and told me that being partially deaf, he could not gauge the power of his voice But, somehow, I always thought that his quiet voice was all a part of the gentleness of the man, and gentle he was, I never saw him angry, sometimes indignant at the obviously wrong perhaps but *never angry* "

But it is perhaps as a teacher that Sprawson will be rememberd, and the last word must lie with those he taught

"We at the London,' writes S G A, "have very affectionate memories of Sprawson, tall and spare, striding along in a cloud of tobacco smoke, or lecturing in his room in his soft hesitant voice, his words carefully chosen and his subject matter enlivened with interesting reminiscences and literary quotations His kindness and consideration endeared him to all his students and it was a memorable evening in 1947 when a gathering of past and present members of the London Hospital Dental Society presented him with a portrait and announced the institution of the Evelyn Sprawson prize on the occasion of his retirement from the hospital When the final assessment is made it may well be decided that his chief claim to fame was not in his scientific contributions to dentistry but in his success as a teacher, for he who could instil and maintain such a feeling of affection and gratitude in the hearts of all his students must surely have been in possession of a rare gift"

Notes and News

CUT IN DENTISTS' PAY TO END

On March 17 the Minister of Health notified the British Dental Association[1] that he was prepared to abolish the 10% cut in dentists' pay imposed in 1950.[2] He was not satisfied that on purely statistical evidence a case for restoration had been made but in view of the whole position he was willing to end the cut subject to the following conditions:

1. That "the re-assessment of dental remuneration and the recasting of the scale of fees should be dealt with together."
2. That "this should be accepted as a full settlement of dental remuneration at the present time."

The Minister has in mind that the new scale, which is to be drawn up in consultation with the association, should give dentists the net incomes that they would have received in 1952–53 had the 10% reduction not been in effect. While the new scale is being worked out the Minister is willing to cancel the 10% reduction.

On March 31 the remuneration subcommittee of the General Dental Services Committee recommended the rejection of the Minister's offer, mainly on the ground that it would mean giving up for ever the Spens Committee's recommendations and the association's claim, based on them, for a scale which would produce an average net income of £2200. But after consideration the G.D.S. Committee decided not to accept the subcommittee's views but to advise the Representative Board to accept the Minister's offer. The board was impressed by "the danger of refusing something palpable and embarking again on an interminable series of negotiations" and after a full discussion agreed to accept the Minister's proposals.

SCOTTISH REGIONAL HOSPITAL BOARDS

The following doctors have been appointed to the hospital boards. New appointments are indicated with an asterisk.

Northern Regional Hospital Board.—C. B. MacLeod, L. M. V. Mitchell.

North Eastern Regional Hospital Board.—Lady Taylor, H. Gordon Smith.

Eastern Regional Hospital Board.—J. Gordon Clark, A. F. Wood.

South Eastern Regional Hospital Board.—Prof. D. M. Dunlop, T. McWalter Millar.

Western Regional Hospital Board.—Prof. G. M. Wishart, E. G. Butler, D. Livingston Kerr.

SALE OF HORMONES

The council of the Pharmaceutical Society of Great Britain is advising pharmacists not to supply sex hormones or preparations containing them unless they are satisfied that customers are obtaining them on medical advice, though not necessarily presenting a prescription. No decision has yet been reached about cosmetic preparations containing hormones.

IDIOPATHIC THROMBOCYTOPENIC PURPURA

In our recent leading article[3] we referred to a report by Tullis[4] that serum from some patients with idiopathic thrombocytopenic purpura caused agglutination and even lysis of normal platelets in the presence of complement. In an earlier report[5] Dausset et al. in Paris had recorded a similar finding: the serum of a patient with acute idiopathic thrombocytopenic purpura caused rapid agglutination followed by destruction of normal platelets in vitro and inhibition, in the presence of calcium, of clot retraction of normal blood or of recalcified citrated plasma.

A HANDMAID OF MEDICINE

The Medical Artists' Association of Great Britain has gathered together in an exhibition called Art in the Service of Medicine, and held at British Medical Association House, Tavistock Square, W.C.1, an imposing array of drawings intended to illustrate the training and scope of medical artists. Most of the exhibits are drawings or paintings of medical subjects, but there are also wax models and castings in plastic resin of bronchial trees and cerebral ventricles. As works of art for pathological museums and the walls of dissecting rooms the exhibits are excellent, but insufficient emphasis is laid on the preparation of drawings and paintings for illustrating published articles. The requirements of blockmakers and printers are neglected except for one original painting set by the side of the final reduction in print and another original painting set alongside the different stages of its reproduction by seven-colour offset lithography. These two exhibits illustrate the way in which the blockmakers and printers deal with the artists' material rather than the way in which the artists meet their requirements. In this wealth of beautiful drawings there is but one chart, and that depends on colour to distinguish between the curves. These last two items are far from practical. It is to be hoped that a similar exhibition will become an annual affair at which much more attention will be paid to charts, diagrams, and other illustrations intended for reproduction in medical books and journals.

SOCIAL MEDICINE IN THE SOUTH SEAS

There are no half measures about the South Sea Islands. They either bring out the worst or the best in people. In Dr. Davis and his wife they have brought out the best, as is shown by their joint account of his foray into social medicine.[1] Of Welsh and Polynesian descent, he was born in the Cook Islands, graduated in medicine in New Zealand during the war, and returned to the Cook Islands with his wife, a New Zealander, to lead a campaign for the improvement of health and living conditions which had been disrupted by the falling economy of the war years. The story of this campaign, with his triumphs and disappointments, his battles against the administration, and his efforts to gain the confidence of the islanders, is delightfully and modestly unfolded. He set about his task with the zeal of a missionary, and he was well armed with his knowledge of and sympathy with the islanders' point of view. He fought the old prejudice against modern medicine, yet was able to gain the support of the witch doctors, who despite laws passed against them still flourished. In the teeth of opposition he sided with the islanders in their efforts to secure a greater share in administration of the islands and in repelling the Communist infiltration which had been encouraged by the economic depression. The final chapters tell of a voyage in a tiny sailing ship which Dr. and Mrs. Davis, with their two small sons and a crew of two, made in mid winter across the Pacific to South America and ultimately to the United States.

This story of high courage and adventure, told with simple sincerity and quiet wit, will delight those who like to hear about solid achievements in social medicine, and also those of us who, like Tartarin de Tarascon, dream of stirring deeds but are too timid to cross the bridge over the river.

University of Oxford

Dr. G. W. Pickering, who holds a chair of medicine in the University of London at St. Mary's Hospital Medical School, has been appointed regius professor of medicine. He will take up his appointment next year when the laboratory and unit of 25–30 beds now being built at the Radcliffe Infirmary for his department will be completed. Professor Pickering is to be the first regius professor of medicine to occupy the house in Norham Gardens which Osler bequeathed to the university.

Dr. Pickering, who is 50 years of age, was educated at the Royal Grammar School, Newcastle upon Tyne, at Dulwich College, and at Pembroke College, Cambridge, where he was a scholar. He obtained a first-class in both parts of the natural sciences tripos and in 1926 went to St. Thomas's Hospital. While working as a student he taught biology at Westminster School. In 1928 he qualified, and in the following year he was awarded the Mead medal and Wainwright prize for medicine at the hospital. He was resident anæsthetist and house-physician, and in 1930 graduated M.B. Camb. and became M.R.C.P. From St. Thomas's he went to University College Hospital as assistant in the department of clinical research under Sir Thomas Lewis, F.R.S. In 1931 he was appointed to the permanent scientific staff of the Medical Research Council. In 1932 he presented with W. Hess a preliminary account of his work on the experimental production of headache. This was followed by many other reports, especially on experimental hypertension and allied problems, and in 1936 he became lecturer in cardiovascular pathology. In 1938 he was appointed Herzstein lecturer in the University of California and Stanford University, San Francisco, and spent two months visiting these and other schools in the United States. He was elected F.R.C.P. in 1938. The following year he took up his present chair at St. Mary's. In 1949 he visited Australia, New Zealand, and Africa as a Sims travelling professor. He has been a member of the University Grants Committee (1944–54), and was last year appointed to the Medical Research Council and the Clinical Research Board.

University of Durham

On Thursday, May 19, at 5 P.M., a memorial plaque to the late Professor Grey Turner will be unveiled in the Royal Victoria Infirmary, Newcastle upon Tyne. Afterwards Sir Zachary Cope will deliver the first Grey Turner lecture. He is to speak on Some Early Medical Museums.

Dr Douglas Guthrie during the summer term will give six lecture demonstrations surveying early medicine At the first lecture on May 2, at 5 P M, at University New Buildings, Teviot Place, he will speak on Magic, Witchcraft, and Medicine

Royal College of Physicians of London

On Tuesday and Thursday, May 3 and 5, at 5 P.M, at the college, Pall Mall East, S W 1, Sir Horace Evans will give the Croonian lectures on the Significance of Certain Symptoms and Signs in Disease of the Kidneys

Royal College of Physicians of Ireland

On April 1 the following were admitted to the licence of medicine and midwifery of the college

Cassam Mahomed Bahemia, M J Doyle, Jalejar Burjorji Fanibunda, M H Heller, J S P MacGill, Cecilia M. McMorrow, B M. Rosovske, Muriel M. Tynan

Royal Institution of Great Britain

On Friday, May 20, at 9 P M, at the Institution, 21, Albemarle Street, London, W 1, Sir Wilfrid Le Gros Clark, F.R.S, will give a discourse on the Exposure of the Piltdown Forgery

Institute of Dermatology, London

A semipermanent exhibition by Dr L Forman, on Cutaneous Reactions Associated with Visceral Malignancy, will be open from May 5 to 25

Israel Medical Association

The third world assembly of this association will be held in Israel from Aug 10 to 20, with sessions at Jerusalem, Haifa, and Tel Aviv Further details may be had from Dr H Farkas, Embassy of Israel, 2, Palace Green, London, W 8

Medical Women's Federation

Psychological Medicine Group —At a meeting of this group, to be held on Friday, May 6, at 2 45 P M, at the Cassel Hospital, Ham Common, Richmond, Surrey, Dr T F Main will speak on Emotional Disturbance at Adolescence

St Mary's Hospital, London

Dr A. C Corcoran, medical director of the research division of the Cleveland Clinic, will give a lecture in the medical school at 5 P.M on May 24, on the Evaluation of Antihypertensive Drugs

Naval Medical Compassionate Fund

A meeting of the subscribers of this fund will be held at 3 P M on May 13, at the Medical Department of the Navy, Queen Anne's Mansions, St James's Park, London, S W 1, to elect six directors of the fund

Hunterian Society

The gold medal of this society for 1954 has been awarded to Dr Philip Hopkins The subject for the 1955 essay is Headache The competition is open to all general practitioners, and further details may be had from the hon secretary, Mr R S Murley, 95, Harley Street, London, W 1

Faculty of Homœopathy

At Hahnemann's 200th birthday celebration, to be held at 1, Wimpole Street, London, W 1, at 3 P M on Thursday, May 5, Dr F H. Bodman will speak on Hahnemann and his Patients, and Dr T Douglas Ross on Homœopathy's Heritage and Outlook Today Tickets may be had from the assistant secretary of the faculty, Royal London Homœopathic Hospital, Great Ormond Street, W C 1

Wright-Fleming Institute of Microbiology

Sir Zachary Cope will give the first of six Almroth Wright lectures at St Mary's Hospital Medical School, Paddington, W 2, on Tuesday, May 3, at 5 P.M He will speak on Peculiarities of the Clinical Pathology of Actinomyces The other lecturers are Dr D A Long (Response of the Host to Bacterial Infection), Mr A. T R Mattick, PH.D (Lactobacilli and some Streptococci), Lord Stamp (Action of Bacterial Enzymes on Immunising Antigens), Prof A C Frazer (Intestinal Function in Man), Prof B Ephrussi (Paris) (Intrinsic Factors Controlling the Synthesis of Cytochromes in Yeast) The lectures are open to all doctors and medical [illegible]

Society of Chiropodists

The annual dinner of this society will be held at Park Lane Hotel, Piccadilly, London, W 1, on F May 13

Worshipful Company of Barbers of London

At a meeting of the court of the Barbers' Company held a Tallow Chandlers' Hall on April 5, Sir Cecil Wakeley, Master, admitted Sir James Paterson Ross as an freeman

---

The National Smoke Abatement Society has moved to [illegible] Chambers, Bridge Street, London, S W 1

Diary of the Week

APRIL 24 TO 30

Monday, 25th

ROYAL SOCIETY OF MEDICINE 1, Wimpole Street W 1
8 P.M *Pathology* Prof René J Dubos (New York) Effect of Metabolic Factors on the Infectious Process

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W 1
8 30 P.M. Dr J G Scadding Treatment of Pulmonary Tub culosis (Second Lettsomian lecture)

HUNTERIAN SOCIETY
8 30 P M (Talbot Restaurant, London Wall, E C 2) Pr E N de C Andrade, F R.S Isotopes

MANCHESTER MEDICAL SOCIETY
9 P M (Medical School) *General Practice* Dr Edmund Phill Aspects of General Practice

Tuesday, 26th

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fiel W C 2
3 45 P M Prof R. J Last Form and Structure of Musc (Arnott demonstration)

ROYAL SOCIETY OF MEDICINE
8 P.M *Medicine* Prof E E Pochin Prof D W Smith Mr Norman Veall Radioactive Isotopes

Wednesday, 27th

MEDICAL SOCIETY OF LONDON
8 30 P.M Dr Scadding Treatment of Pulmonary Tuberculosi (Last Lettsomian lecture)

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATIO
8 30 P M (Royal Free Hospital School of Medicine, 8 Hunt Street, W C 1) Dr Dorothy Parkin Dr Helen Payli Wright, Miss Josephine Barnes Obstetric Problems General Practice

Thursday, 28th

ROYAL COLLEGE OF SURGEONS OF ENGLAND
5 P M Dr W T Cooke Nutritional and Metabolic Factors in th Ætiology and Treatment of Regional Ileitis (Hunte lecture)

UNIVERSITY OF LONDON
5 30 P M (London School of Hygiene and Tropical Medici Keppel Street W C 1) Professor Dubos Micro Envir ment of Inflammation or Metchnikoff Revisited

LONDON JEWISH HOSPITAL MEDICAL SOCIETY
8 30 P.M (11 Chandos Street, W 1) Dr I R. Marre Comm Skin Diseases

NUFFIELD ORTHOPÆDIC CENTRE Wingfield Morris Orthop Hospital Oxford
8 30 P M Mr R G Taylor The Brown Séquard Syndro following Trauma

HONYMAN GILLESPIE LECTURE
5 P M (University New Buildings, Teviot Place Edinbur Prof G J Romanes Motor Cells of the Spinal Cord

UNIVERSITY OF ST ANDREWS
5 P.M (Medical School, Small's Wynd, Dundee) Dr W Feldber F R.S A New Experimental Approach to the Pharmac logy of the Central Nervous System

Friday, 29th

UNIVERSITY COLLEGE Gower Street, W C 1
5 15 P M Dr S E Dicker Renal Clearances in Mammalia Kidneys (First of ten Cushny lectures)

ST MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W 2
5 P M Mr Ian Jackson Ectopic Gestation

INSTITUTE OF LARYNGOLOGY AND OTOLOGY, 330, Gray's Inn Ro W C 1
3 30 P M Mr J C Ballantyne Use of Hearing aids

UNIVERSITY OF OXFORD
NOON (Sir William Dunn School of Pathology) Professor Dubo Fate of Infectious Agents in vivo

Births, Marriages, and Deaths

BIRTHS

CLARKE —*On April 14, at Gosforth to Catherine wife of M* Patrick Clarke F R C.S —a son

TURNER WARWICK.—On March 25, to Margaret (née Harvey Moore) M R.C P, wife of Richard Trevor Turner Warwick, F.R.C. M R.C P—a sister for Gillian (Lynne Frances)

OSTEOPOROSIS*

A M. COOKE
D.M. Oxfd F.R C P
PHYSICIAN TO THE RADCLIFFE INFIRMARY OXFORD

THE SKELETON, out of sight and often out of mind a formidable mass of tissue occupying about 9% of e body by bulk and no less than 17% by weight As apper (1952) has cruelly said, When budding ysicians are first introduced to osteology, the skeleton ems to be only a collection of oddly shaped tubes and ates consisting of calcium carbonate and calcium osphate and most members of the medical profession erish this first impression for the rest of their lives' he stability and immutability of dry bones and their istence for centuries, and even millions of years, ter the soft tissues have turned to dust give us a false ea of bone during life Its fixity after death is in sharp ntrast to its ceaseless activity in life Bone is in fact e of the most plastic tissues in the body with a large etabolic *turnover, and ceaseless chemical and physio*gical activity throughout life It is a living tissue with ood vessels, nerves, and lymphatics

The Structure of Bone

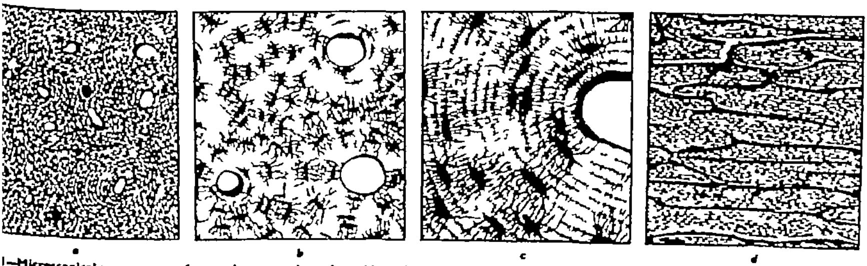
The gross anatomy of bone is too well known to quire more than passing comment The compact bone best seen in the shafts of the long bones The cancellous ne fills the ends of the long bones and the centra of the rtebræ and forms the greater bulk of small bones e anatomist s division of bones into the somatic and eral skeletons need not concern us here nor need we more than note in passing the division of the skeleton o cartilage bones and membrane bones The latter sification is of interest and importance from the int of view of development but once bone is formed, hatever the method of ossification its structure and ysiological behaviour are the same

n compact bone (fig 1) sections show the cylindrical versian systems consisting of a Haversian canal ntaining blood vessels and sometimes lymphatics rounded by concentric lamellæ (Havers 1691) The es between adjacent Haversian systems are occupied irregularly disposed interstitial lamellæ On the side, for example of the shaft of an adult long bone, the outer circumferential lamellæ which give a ooth surface to the bone and similarly on the inside e inner circumferential lamellæ. The general direction he Haversian canals is longitudinal, although they are united by oblique branching canals There are also canals at right angles to the bone surface by which nutrient vessels enter from the periosteum and communicate with the Haversian canals These are known as Volkmann s canals and were originally thought to be caused by blood vessels burrowing into the bone This is now known to be an incorrect view because all blood vessels in bone are developed in the matrix before ossification occurs. These canals are still known somewhat undeservedly by Volkmann s name

Cancellous bone consists of trabeculæ arranged either in a random three-dimensional lattice or condensed into so called lines of force" or trajectories Actually compact and cancellous bone are essentially the same in structure Both contain laminæ, and cancellous bone may contain Haversian systems They differ only in their spatial arrangement Every bone surface other than those forming joints is covered by a membrane on the outside inside the medullary canal, and over the surface of every trabecula This membrane is of course, known as the periosteum on the outside of the bone and the endosteum on the inside, but its function is precisely the same in both situations The bone membrane contains osteogenic cells and plays a vital part in bone growth

This is no place to enter into the interesting controversy about the function of the periosteum that has raged for two hundred years Equally competent and careful workers have performed the same experiments and obtained exactly opposite answers—on the one hand that the periosteum can produce bone *de novo* and on the other that its function is to limit and restrict the growth of bone Indeed, Sir Arthur Keith was forced to conclude that it looked as though the dogs of Edinburgh and Lyons were provided with a different kind of periosteum from the dogs of Glasgow The explanation is now thought to be that the naked eye periosteum is different from the microscopic periosteum The former has two layers, an outer and obvious connective tissue layer and an inner and scarcely visible layer containing osteogenic cells When periosteum is stripped from bone, the outer layer is removed but part of the inner layer with its osteogenetic possibilities remains adherent to the *bone and part to the main sheet* of periosteum (Ham 1934) This proves both sides of the controversy to have been right but has made the papers of modern authors on bone growth rather less exciting

The shape of a bone is determined by various factors. The first is an intrinsic growth pattern presumably related to the presence of organisers Murray and Huxley (1925) Willis (1936) and others have shown that a tissue-culture of the axial mesoderm of a limb bud will show a surprising degree of anatomical development In the case of the lower limb the tissue-culture differenti



1—Microscopical appearances of normal compact bone from Hassall (1849) a b and c are low medium and high-power transverse sections and d a low-power longitudinal section ates into a recognisable femur, with head, neck, trochanters, and condyles, and may even show the beginnings of joint formation Secondly, the shape of a bone is modified by the mechanical forces that the bone is there to resist Numerous observations have shown that if by accident in man, or by experiment in animals, a limb is deformed or one of the bones in the forearm removed, all the bones in the limb will rapidly adapt themselves to the new functional requirements This phenomenon is related to the disposition of the trabeculæ and the formation of trajectories, about which I shall have more to say shortly Thirdly, some bones are modified by the soft organs which they enclose—the skull by the brain, the ribs by the lungs, and the otic, optic, and nasal capsules by their contents Fourthly, bones must compromise with neighbouring organs, as shown in the human tibia which is moulded by lateral pressure of the muscles lying against it Fifthly, the shape of a bone may be influenced by the earlier structures that it has superseded, such as the relation of early cancellous bone to its preceding cartilage The last factor is respect for the needs of the other functions of bone—for example, leaving room for the marrow (Murray 1936)

---

*ridged from the Lumleian lectures for 1955 delivered before the Royal College of Physicians of London on April 10 and 21 under the title of Some Aspects of Skeletal Disease

Bone under Stress

Of these factors, one which I should like to deal with in greater detail because it is relevant to my general theme is the second—namely the effect of stresses and strains on bone This is a problem that has exercised anatomists, zoologists, and physiologists for over a century As long ago as 1827 Sir Charles Bell wrote that "This minute lattice work, or the cancelli which constituted the interior structure of bone, have still reference to the forces acting on the bone" Most writers name the year 1886 as the start of the more scientific study of the structure of cancellous bone Professor Culmann, professor of engineering at Zürich, is said to have had occasion to enter the dissecting room of his anatomical colleague, Professor Meyer, and there happened to notice a longitudinal section of the head of a femur Culmann had just been designing a crane and at once recognised the arrangement of the bony trabeculæ as nothing more or less than a diagram of the lines of stress In fact he is said to have cried out "That is my crane" Culmann and an anatomist, Wolff, wrote a paper comparing the crane to the femur (Thompson 1942)

Actually, Culmann, Meyer, and Wolff were anticipated by nearly half a century by a little-known Englishman In 1838 F O Ward published in London a little book called *Outlines of Human Osteology* This work has not received the attention it deserves—at any rate not in Oxford, for when I took the copy out of the Bodleian Library the pages were uncut Ward pointed out that the neck of the femur resembled a wall bracket in which some members are in tension and some in compression He described this clearly in the text, and illustrated it with the drawing shown in fig 2

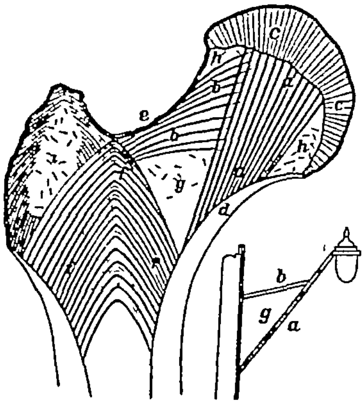


Fig 2—Drawing from Ward (1838) comparing the trajectories femoral head with a wall bracket. In both figures the mem are in compression and the members *b* in tension

When a block of any material is subjected to force, it temporarily changes its shape because of its elastic properties These small changes are called strains, and the internal forces which resist the deforming actions of the external forces are called stresses A strain is a linear movement, that is a matter of direction, but a stress is a force measured across an area of a plane Whatever the nature of the external forces—tension, pressure, or shearing—and however complicated, at every point in any plane section there are two directions of principal stress, always at right angles to one another The stress in one direction is the maximal tension, and the other the maximal pressure In the direction of the principal stresses there are no shearing stresses, but these will be present in any other direction It is thus [illegible] draw lines on any imaginary section of a body along the direction of probable stress These lines a be straight or curved, but at all points in the bod two sets of lines remain at right angles to each other, the closer they are together in any region, the greater probable stresses in that region, and vice versa fundamental idea in the trajectorial theory of b structure is that the trabeculæ of cancellous bone fo the line of trajectories in a homogeneous body of same form as the bone, and stressed in the same w This was the theory based on Culmann's crane an Meyer's section of the femoral head The theory however, been criticised on the ground that the tr tories are lines drawn from a number of arbit selected points at certain distances from each o If all possible lines were drawn, the diagram would completely black, for the number of possible traject is infinite In bone, therefore, we reach the parado conclusion that if trajectories and nothing else determ the arrangement of the trabeculæ all cancellous b would have to be compact bone Something els required to account for the existence of a lattice struc at all Another objection is that if trabeculæ do cross at right angles, they are not trajectorial A any bone section a number of trabeculæ can be se cross at angles other than 90° On the other hand, of the trajectory diagrams of bones consider only transmission by the bone (for example the femur) of body-weight and take no account of the numerous complicated stresses produced by muscular act Whatever the rights and wrongs of the traject theory, the trabecular arrangement of bone is modi by the stresses to which bone is subjected An elabor anatomical and mathematical analysis of the hu femur by Koch (1917) has shown beyond doubt stresses do determine the thickness, closeness of spac and arrangement of the trabeculæ

Apposition and Resorption

Bone is a form of connective tissue consistin ground substance and collagen fibres, in which have deposited crystals of a calcareous material which re the structure more rigid than the other tissues of body The collagen fibres of bone are continuous the rest of the connective tissues of the body, w indeed form continuous sheets of tissue, and is no reason to think, as far as microscopy or chemis can tell us, that bone collagen is substantially diffe from any other sort of collagen fibre This vie supported by the fact that bone can be laid down in varied tissues as the eye, meninges, tonsils, lu thyroid, ovaries, fallopian tubes, uterus, penis, kid arteries, operation scars, muscles, fascia, and tend It is only right to say that ectopic ossification oc only as the result of some pathological process and in the presence of the reactive proliferation of young connective tissue or granulation tissue It is not the type of pathological condition but the regenerative process common to all that counts

The bone cells or osteocytes have long protoplasmic processes which communicate with the adjacent Haversian canal and with the processes of other nearby bone cells The life of bone depends on its osteocytes If an osteocyte dies or is killed resorption takes place If the process is extensive resorption takes so long that a piece of dead bone separates—i.e the patient develops a sequestrum

The life of an osteocyte depends in turn on the availability of blood supply In the bone of dogs the maximum distance of an osteocyte from a capillary is 0 2 mm and most are within 0·1 mm That is why a large trabecula more than 0·2 mm across usually has a central blood vessel (Ham 1952) It also explains why bone, in common with other vascular tissues is very susceptible to interference with its blood supply

There have been various controversies about the origin, nature function, and mode of action of osteoblasts and osteoclasts. It is now generally agreed that whatever the detailed answers to these questions it can be taken that the presence of osteoblasts on a bone surface means that bone is being laid down and the presence of osteoclasts that it is being resorbed These facts enable the histologist to say what processes were going on at the moment that the bone was killed or fixed Moreover bone carries in its structure indelible records of its past history When growth ceases a chemical change takes place in the lamina at the surface that gives a different staining reaction—the so-called cement line If the line is straight, it is called a resting line and means that growth ceased there and was then resumed If bone resorption is in progress the erosion by osteoclasts is irregular, causing dents in the bone—Howship s lacunæ If the process is then changed to growth by apposition the wavy cement line so caused is known as a reversal line It is often possible to see where a new Haversian system has invaded old ones and sometimes three generations of Haversian systems can be identified

It is generally agreed that all changes in the shape of normal bones, whether macroscopic or microscopic occur by resorption and apposition at bone surfaces. And the term surface must here be used in the widest and most literal sense because it includes not only the outside of the bone, the inside of the medullary cavity (if it is a *long bone*) and the surface of every *trabecula*, but *also* the inside of every Haversian canal and Volkmann s canal The reactive surface of bone is an immense area.

As about 99% of the calcium in the body is situated in the bones, it is natural to suppose that it forms a reserve that can be called upon to provide calcium for other purposes Calcium ions are of course concerned in such vital functions as neuromuscular activity and clotting of the blood In pregnancy and lactation, too requirements are great In starvation the body conserves protein iron sodium and potassium but the excretion of calcium and phosphorus continues at the same level as in normal circumstances Nevertheless, the blood levels of calcium and phosphorus remain normal so there must be a drain from the skeleton There is reason to think that this occurs equally from all bone surfaces Therefore the effects are much more obvious in cancellous bone than in compact bone. If one imagines a single lamina to be removed from say the compact bone of the shaft of the femur which is $^{1}/_{4}$ in thick, there would be no appreciable difference but the removal of a lamina from each side of a thin trabecula would be a much greater proportional change

The Organic Matrix

As I have said bone is first and foremost a variety of connective tissue It is calcified and rendered hard as a secondary phenomenon The fact that after death the mineral part of bone persists long after the organic part has disappeared must not delude us into neglecting the importance of bone matrix It is indeed the most important part of bone because, although it is possible to have histological bone without calcification, it is not possible to have bone at all without a scaffold of matrix The organic part of bone comprises over half its weight and about two thirds of its volume It is composed of cells osteocytes osteoblasts and osteoclasts, the collagen fibres and the cement substance

In immature bone—that is, in the young animal or in rapidly formed bone such as callus around a fracture—the collagen fibres are laid down in an irregular feltwork, so-called fibrous bone In adult bone and callus which has had time to rearrange itself the fibres are organised in regular laminæ so called laminated bone The laminæ show a remarkable arrangement of collagen fibres where alternate layers are at right angles to one another with other layers between them placed obliquely (Lacroix 1951) This device anticipates by a few million years reinforced concrete plywood and laminated plastics and gives great physical strength both in compression and tension

The fibrous nature of bone can be easily demonstrated by pricking it with a round sharply pointed instrument such as an awl The point makes a round hole but when it is withdrawn leaves a linear split, or cleavage line which indicates the general direction of the collagen fibres in the outer circumferential lamellæ (for general reviews, see Armstrong 1944 Weinmann and Sicher 1947 Ham 1953)

Study of the more minute structure of bone takes us into a microscopic and submicroscopic world of bewildering complexity but I would like to remind you of some of the established facts that have bearings on bone function The ordinary light microscope has a maximum resolution of about 2000 Å (1 Å is a ten millionth of a millimetre) The electron microscope has a maximum resolution of about 20 Å—that is about one hundred times that of the light microscope The light microscope enables us to distinguish bundles of collagen fibres. Studies by polarised light and X ray diffraction reveal indirectly the orientation of collagen fibres and bone crystals The application of electron microscopy has enabled the actual bone crystals to be measured and photographed (Robinson 1952) The sequence of events in bone formation seems to be that the osteoblasts *produce the primitive matrix after which phosphatase* appears in the cell and later in the matrix itself As the matrix matures collagen fibres appear and the cement substance undergoes changes that cause it to stain metachromatically Then but not before bone crystals are deposited and bone results The electron microscope also enables us to see clearly the differences in arrangement of the collagen fibres in fibrous and laminated bone

The Mineral Constituents

The mineral constituents of bone are equally complex (Huggins 1937 Nicolaysen Eeg Larsen and Malm 1953) The main constituent of bone mineral is a double salt of calcium phosphate and calcium carbonate (Logan 1940) For some reason that I have never been able to understand writers on this subject seem determined to show that this substance is the same as some known mineral dug up from the earth It has been variously identified with dahlite apatite hydroxyapatite and francolite. There is no biological reason why it should be a terrestrial mineral and equally no reason why it should not be a substance peculiar to bone

The skeleton contains not only 99% of the total calcium in the body but also 90% of the body citrate

80% of the body carbonate, 25% of the body sodium, and 8% of the body water. The citrate, carbonate, and sodium are thought to lie in the cement substance in relation to the surface of the calcium phosphate crystals. There can be little doubt that these constituents of bone other than calcium and phosphorus fulfil important physiological functions, but little or nothing is known of the details.

Bone crystals are blocks of about 500 × 250 × 100 Å lying in the cement substance and in alignment with the collagen fibres. The rigidity of bone is thought to be due to the adhesion of the crystals one to another, to adjacent collagen fibres, and to the protein molecules of the ground substance by the attraction of hydrogen bonds. Bone can undergo small plastic deformations in which the crystals slide over one another. The efficiency of this process depends on the physical state of the cement substance; hence the greenstick fracture of the child and the brittle bones of the aged. The ageing of bone matrix is similar to that of intercellular substance in other parts of the body—namely, a slow process of dehydration. The water content of young bone is 30% and of old bone only 20%.

Some idea of the size of bone crystals may be gained from the fact that if they were magnified until they were just visible to the naked eye, or 0·5 mm. across, a man's femur on the same scale would be about three miles along. Their small size gives them a large surface area. One gramme of crystals has a surface area of 106 sq. metres; so the total area of a man's bone crystals is nearly 100 acres. It might be supposed that this large area would make bone crystals chemically reactive; but, owing to their block-like shape and internal structure, only the outer layers, amounting to 12 to 14% of the whole crystal, are readily available for exchange. Neuman and Weikel (1954) have shown from measurement of the rate of molecular exchange of phosphate ions in different circumstances that it can be postulated that the most rapid rate occurs in the hydration shell that surrounds the crystal, a slower rate with the exchange from the hydration shell to the crystal itself, and the slowest rate of all to the exchange of surface ions with sub-surface ions. This explains the rapid immediate exchange of bone crystals with injected radiophosphorus and also the rapidity with which the radiophosphorus can leave the skeleton again. The main mass of bone crystal is not in fact very reactive. The sodium in the bone behaves in a similar manner. Only about one quarter is available for exchange with radiosodium, and equilibrium is reached with this moiety in about twelve hours. The unexchangeable portion is presumably bound to the crystals of bone mineral and is out of osmotic equilibrium with the body fluids (Miller and Wilson 1953, Edelman, James, Baden, and Moore 1954).

Metabolism

Information about the metabolic activities and the rate of turnover in bone has been obtained from experiments in animals with radioactive phosphorus (Hevesy 1940). Injected labelled phosphate disappears rapidly from the blood, and in two hours only 2% remains. Most of it goes into the extracellular fluid, but some to exchange with various organs. The loss by excretion is negligible in short experiments. Most of the phosphorus retained finds its way into the bones, and after three months 92% of the radioactive phosphorus remaining in the body is in the skeleton. This sounds a large amount, but only a small proportion of the bone phosphorus has exchanged with the radiophosphorus, because there is so much more phosphorus in bone than in blood—about a thousand times as much per gramme weight. As might be expected, the phosphorus uptake is greater in growing bone and in the epiphysis than in the diaphysis. Hevesy, Levi, and Rebbe (1940) administered radiophosphorus in frequent small doses so as to keep it radioactive inorganic-plasma phosphorus constant. Comparison of the radioactivity of bone with plasma, weight for weight, gives an indication of the renewal rate bone. By this method they found that after fifty 29% of the femoral and tibial epiphyses were renewed, but only 7% of the diaphyses. On the other hand, there was a 50% changeover in the scapula.

Since this work, other experiments, for example those by Jowsey, Owen, and Vaughan (1953) with radioactive strontium, have helped to explain these figures. Radio-strontium is taken up by the skeleton, as is calcium, and it is possible to make effective autoradiographs of bones by this means. These observations have shown the very patchy nature of bone building. Intense activity may be present in quite small areas, scattered about sometimes in an understandable manner, and sometimes for no apparent reason; but it is probable that we merely do not know the reason. This patchy activity of normal bone in space is paralleled by its variable activity in time. Bigwood (1952) has pointed out that a normal man may be in negative calcium balance for a few days, and then in positive calcium balance for a few days for no apparent reason, but no doubt depending on the algebraic sum of bone resorption and bone apposition. Experiments by Govaerts and Dallemagne (1948) with radioactive phosphorus have shown that, when medullary new bone is built, nearly half the phosphorus does not come from the freely available radiophosphorus fed or injected, but from phosphorus already stored in the skeleton. This reminds us of the constant turnover of phosphorus and calcium from bone surfaces for use at other sites. Conversely, experiments by Greenberg (1939) have shown that although phosphorus exchange occurs in the more vascular parts of bone, in the growing animal at any rate, it is not long before it is redistributed all over the skeleton. He estimated that the average stay of a phosphorus atom in the human body was thirty days.

It is important to realise, as Leblond, Wilkinson, Bélanger, and Robichon (1950) in Ottawa have pointed out, that there are two types of reaction of injected radiophosphorus with the skeleton. In the first, which they call "exchange," there is a rapid uptake and rapid release of phosphate. In the second, which they call "precipitation," there is actual formation of new bone, and the radiophosphorus persists at the site. These differences may well be due to exchange with the outer layers of bone crystal in the first instance and deposition of new bone mineral in the second.

Making Old Bones

The remoulding of the trabeculæ of the child to adult form is part of a process that continues every hour until the person's death. It is true that it takes place irregularly in space, but in every one of us there is at any given moment in some part of the skeleton active destruction going on, and elsewhere equally active rebuilding, with the expected result that from one year's end to another we show no substantial change. Nevertheless, over a period of years changes do occur because the skeleton, like other tissues, undergoes development and growth, enjoys an all too brief prime of life, and then suffers defervescence.

This brings me to the general question of how long a man should live from the biological point of view. In a state of Nature, the hazards of insufficient food, the depredations of enemies, and the perils of epidemic disease give many species a hard struggle to maintain their existence. Few animals survive long beyond the end of the reproductive epoch, even in the protection afforded by captivity. Indeed, some species have special mechanisms to bring about the death of the individual after reproductive powers have ceased.

The human species broadly speaking reproduction ceases in women about 50, and potency and fertility are greatly diminished in men after this age It might be argued that owing to the helplessness of human babies and children *they need parental protection* in the biological sense at any rate until nubile, that is to say about 15 years On these terms, Nature would not require us to survive much beyond the age of 65 and if we do so it is at our peril. But the prospect of life of a baby born today is about 59 years for a boy and 63 for a girl, and if *a man survive till 50 he has an average* chance of living to over 70, and a woman of 50 till nearly 75

It might be supposed that Nature would provide mankind with a body that operated with reasonable efficiency till the end of the reproductive epoch because after that the individual is of no consequence as regards continuing the species Common observation shows that there is something in this view The degenerative diseases—cardiac ischæmia cerebral ischæmia cataract osteo-arthritis and the like—are uncommon before 50 and become increasingly prevalent thereafter You will recollect that Osler spoke of the comparative uselessness of men over 40 and the complete uselessness of men over 60. It is after 50 that mankind turns to spectacles false teeth, hearing aids and the other modern devices for making the latter half of life physically tolerable It is not surprising that the skeleton shares in this depressing involution.

Various attempts to assess the normal age changes in the skeleton have been made. It happens that Western Reserve University and Washington University St Louis, possess between them over 4000 carefully documented skeletons collected respectively by Dr Todd and Dr Terry By documented is meant that the age sex race, occupation, and medical history of the former owner of each skeleton is known This is a unique collection of material and has been carefully studied by Ingalls (1931) and others. Briefly total skeletal weight rises from 25 to 30 years falls at 45 rises to another peak at 55, and then steadily declines to 70 and no doubt beyond "The peak at 35 is regarded as the prime of physical life and the decline that follows marks the beginning of deterioration of bony tissue the first real age change a gradual lightening of the bones an increase in their porosity and accentuation of some of the fine surface markings. In a word the bone is past its prime and those physical *characters which enable it to perform its* function and determine its specific gravity and weight suffer a gradual recession from the previous high water mark" (Ingalls 1931)

The second rise to 55 is probably spurious and accounted for by new bone formation around the articular surfaces and in the skull and axial skeleton The final fall carries the total skeletal weight to its lowest adult point The bone becomes light and porous loses some of its elasticity and its factor of safety diminishes

It is this osteoporosis that I wish in particular to describe and discuss.

Osteoporosis Defined and Distinguished

The first of the many difficulties that we encounter is that of terminology Many writers follow Humpty Dumpty—"When *I* use a word it means just what I choose it to mean"—and the literature of metabolic bone disease abounds in loose and apparently little understood terminology

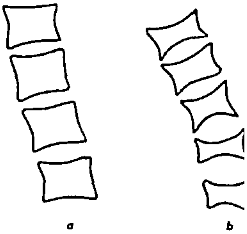

Fig 3—Drawings from X-ray films the outlines of (a) normal and (
osteoporotic centra.

The general term *decalcification* is used to describe X ray appearances or post *mortem findings* in which the bones appear to be deficient in mineral salts, or are unduly thin soft or brittle and there is no *clear reason for this* occurrence These changes may be due either to too little bone substance or to made quately calcified bone matrix Decalcification is not in itself an undesirable term but it is usuall possible to be more precise

Osteomalacia—literally softening of the bones—is use to describe the condition of the bones arising fro deficiency of calcium or vitamin D or both The clinic picture X ray changes, biochemical findings histologic features and treatment are wholly specific for th condition and it is plainly undesirable to use the ter for any other disease Nevertheless, the word is ofte used as a synonym for osteoporosis in such phrases senile osteomalacia and even postmenopausal oste malacia There are of course no such diseases and th patient either has osteomalacia from deficient calcif cation of osteoid tissue or he has not

Osteoporosis—literally porosity of bone—is likewis used loosely to mean decalcification of unknown ætiolog but since the work of Albright (1947b) has come to hav a specific meaning The term is now reserved for the deficiency of bone arising from insufficient matrix formation in the presence of normal calcification of osteoid tissue As the term has a clearly defined meaning it is most desirable that its use should be kept precise and reserved for the condition of inadequate bone formation from lack of matrix.

Halisteresis—literally deprivation of salt—is a term that has been used to describe the state (now believed to be non-existent) where bone mineral is removed leaving osteoid tissue or uncalcified matrix There is no evidence that such a state of affairs ever occurs and if bone is destroyed the destruction involves matrix and mineral equally and *simultaneously* The *only objection to this* general rule is the observation of Ham (1952) that in a Howship s lacuna it is sometimes possible to see in the concavity a minute brush like fringe which could be interpreted as the ends of collagen fibres projecting from

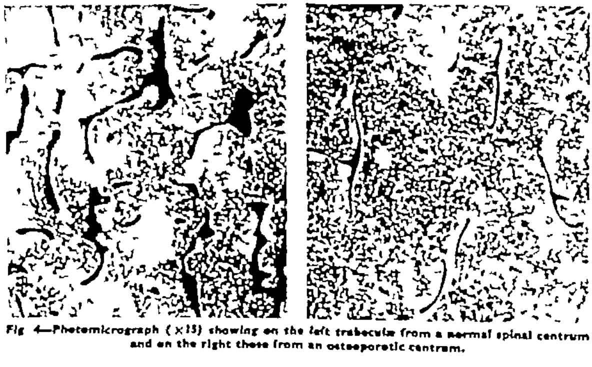

Fig 4—Photomicrograph (×15) showing on the *left* trabeculæ from a normal spinal centrum and on the right those from an osteoporotic centrum.

the bone under destruction There is certainly no evidence of any widespread demineralisation of matrix as a feature of natural bone resorption or pathological bone destruction The term halisteresis has therefore died out in English and American writings, though it has lingered on in France and South America Like the other terms, it is liable to misuse

The distinction to which I particularly wish to draw your attention is that between *osteoporosis* and *osteomalacia*, because here confusion of terminology may lead to confusion of diagnosis, and hence to the wrong treatment of patients

Strictly speaking, osteoporosis is a pathological diagnosis and can be made with certainty only by the morbid histologist, but there are a number of clinical features and X-ray appearances which often justify this diagnosis in the living

The salient feature of the morbid anatomy is that there is atrophy of bone The trabeculæ are fewer and thinner than normal In the spine this causes the centra to shrink and be compressed, chiefly in their central part, so that they become biconcave (so called "fish vertebræ") The intervertebral discs expand and become biconvex (fig 3) The nucleus can absorb water and enormously increase in size, exerting great pressure as it does so These expanded discs and Schmorl's nodes can occur together The spine as a whole shows a rounded kyphosis and is shorter than normal The osteoporotic deformities, which are slight in the neck, become increasingly evident from above downwards and are usually most advanced in the lumbar region

The histological picture is that there is simply too little bone what there is consists of bone of normal structure (fig 4) It may be in the state of undergoing resorption, of being stationary, or of growing by apposition of new matrix and new bone

(To be concluded)

A MORPHOLOGICAL CRITIQUE OF TEMPORAL LOBECTOMY

L Crome

M C, B Com Edin., M.R C.P E

NEUROPATHOLOGIST, THE FOUNTAIN HOSPITAL, LONDON

The diagnosis of "temporal lobe" epilepsy is being made more frequently and the practice of temporal lobectomy is growing As the case in favour of this operation rests partly on the discovery of lesions in all the resected lobes (Earle et al 1953, Falconer 1954, Meyer et al 1954, Liddell and Northfield 1954), it may be useful to record findings which throw doubt on the significance of these structural abnormalities

The abnormalities recorded are of two kinds (*a*) lesions with distinctive features (such as tumours, cysts, hamartomata, and scars) usually circumscribed and obvious to the naked eye, and (*b*) lesions with less easily defined morphology, usually diffuse and only apparent microscopically The latter form the majority—14 in the series of 18 of Meyer et al (1954) and 100 in the 157 of Earle et al (1953) They consist mainly of meningeal fibrosis, cellular proliferation in the white matter, sclerosis of the Ammon's horn, cortical atrophy, and subpial gliosis, one variant of which is the "incisural sclerosis" mentioned by Earle and his colleagues

This paper presents evidence that similar lesions can be found occasionally in the temporal lobes of people with no epilepsy, that when they occur in epileptics they are not confined to one of the temporal lobes, and that they are quite common in mental defectives whether or not these have fits

Temporal Lobes in Non-epileptics

The temporal lobes of 29 non epileptic patients (controls) were examined for microscopical diffuse lesions. Coronal blocks were embedded in celloidin, and sections 20 µ thick were prepared and stained with cresyl violet and with phosphotungstic acid and hæmatoxylin

It became obvious at once that, if the lesions were only slight, their detection was a very subjective matter Judging by the illustrations provided in the biopsy reports cited above, many areas of the temporal lobes of several of these controls were likewise pathological, while some showed greater abnormality (tables I and II) Further, neither of the above-mentioned stains gave consistent results always It therefore proved necessary to record some results as doubtful

Table I shows that in 8 non-epileptic patients the following structural abnormalities were found in the temporal lobes meningeal fibrosis (6), subpial gliosis (6), cortical atrophy, including diffuse cellular degeneration (5), and gliosis of white matter (4) No sclerosis of the Ammon's horn was observed

Table II shows that in 21 non epileptic but mentally defective patients the abnormalities were fibrosis (13), subpial gliosis (15), cortical atrophy (15 gliosis of white matter (16), and sclerosis of the Ammon' horn (5)

The lesions were more conspicuous in the brains of the mental defectives, but except for sclerosis of Ammon's horn, they were also present in the brains of the mentally normal patients

Temporal Lobes in Epileptic Mental Defectives

I have previously described (Crome 1954) the findings in the brains of 61 mentally defective [illegible] with epilepsy Their mental condition made cl[illegible] of fits uncertain, but the fits were described as major 40, minor in 5, mixed in 5, atypical in 2, and unspecif in 9 Psychomotor phenomena, hallucinations, and nature of any aura could not, of course, be ascertained Electro encephalography was done in 7 cases All records were abnormal but none were described characteristic for "temporal lobe" epilepsy all cases there was some structural abno (table III)

For the present purposes this material was re[illegible] to decide whether the temporal lobes had been affected in any special way Sections of the celloidin embedded material were available in 30 cases (table IV)

As expected, every temporal lobe presented some abnormality, and usually many Comparison of these, however, with lesions elsewhere in the brain made obvious that, apart from sclerosis of the Ammon's horn in 9 cases, none was peculiar to the temporal lobe, nor was there evidence of any significant difference in the extent and distribution of the lesions Moreover, all the lesions were bilateral, except in 2 cases with embolism of a middle cerebral artery, and in none were the lesions restricted to the temporal lobes

The only real difference between the structural abnormalities in the temporal lobes and in other areas was sclerosis of the Ammon's horn in 9 of these cases This is also one of the lesions found in biopsy specimens in "temporal lobe" epilepsy—e g, in 5 of the 14 cases reported by Meyer et al (1954)

Can this sclerosis mean that the fits originate in the temporal lobes? It seems unlikely, since it is well known that this lesion is often found in all forms of epilepsy and is nowadays generally considered to be the result and not the cause of fits—produced, perhaps, by anoxic episodes In the present series, as in many previously published cases, this sclerosis was associated with lesions, particularly sclerosis, in other areas of the brain, there appears to be no reason for attaching special epileptogenic importance to the Ammon's horn and the temporal lobes. Moreover, this sclerosis is by no means constant in biopsy specimens in "temporal lobe" epilepsy and it occurs occasionally in the absence of epilepsy (see above)

TABLE III—THE MAIN STRUCTURAL ABNORMALITIES IN THE BRAINS OF 61 EPILEPTICS

Abnormality	No of cases	Abnormality	No of cases
Reduction in weight	53	Absence of corpus callosum	[illegible]
Ventricular dilatation	46	Atrophic changes associated with retrolental fibroplasia	2
Localised agenesis or atrophy	31	Pachygyria	2
Ulegyria	22	Fusion of frontal lobes	2
Cysts and cavities	18	Mongolism with cerebral abscess	2
Changes of uncomplicated mongolism	1	Mongolism with embolism	[illegible]
Localised or diffuse induration	18	Marked cerebellar sclerosis	2
Fibrosis of meninges (macroscopical)	7	Lipidosis	1
Microgyria	6	Changes associated with gargoylism	1
Tuberous sclerosis	5	Porencephaly	1
Calcification	3	Megalencephaly	1
Obstructive hydrocephalus	2	No gross abnormality	0
Arhinencephaly	2		

It remains to consider what relation these abnormalities in the brains of epileptics who are mentally defective bear to epilepsy in persons of normal intelligence. Though this must be largely speculative, in my experience such lesions, although often more severe, are not usually different in kind from those in other chronic cerebral disorders. Mental defectives with extremely deranged brains present lesions which often are only much magnified reproductions of conditions in more normal people. Hence it would be reasonable to expect in this series lesions characteristic of "temporal lobe" epilepsy. The absence of any significant localisation in the temporal lobe suggests that lesions in biopsy material are also probably not confined to one temporal region. This was so in the single example coming to necropsy in the series of Meyer et al. (1954): changes in one temporal lobe were seen after resection, but similar changes were discovered in the opposite temporal lobe after death.

Structural changes described in biopsy material by previous workers fell, as mentioned above, into two groups—discrete and diffuse. My material suggests that

TABLE IV—STRUCTURAL ABNORMALITIES IN THE TEMPORAL LOBES OF 30 EPILEPTICS

Abnormality	No of cases	Abnormality	No of cases
Reduction in size	24	Microgyria	4
Subpial gliosis	22	Fibrosis of meninges	[illegible]
Partial or localised agenesis or atrophy	15	Tuberous sclerosis	3
Cortical cellular atrophy	21	Calcification	3
Increase in number of glial cells in white matter	20	Pachygyria	2
Ulegyria	12	Softening due to embolism	2
Cysts and cavities	10	Lipidosis	1
Sclerosis of the Ammon's horn	0	Changes associated with gargoylism	1

TABLE I—STRUCTURAL FEATURES IN TEMPORAL LOBES OF NON-EPILEPTIC PATIENTS OF NORMAL INTELLIGENCE

Case no.	Sex	Age (yr.)	Clinical features	Meningeal fibrosis	Subpial gliosis	Cortical atrophy	Gliosis of white matter	Sclerosis of Ammon's horn	Chief additional features
1	M	38	Acute poliomyelitis	+	+	−	Doubtful	−	Staining unsatisfactory
2	M	57	Meningovascular syphilis	+	+	+	±	−	Staining unsatisfactory
3	M	42	Lymphosarcoma of meninges	+	+	+	Doubtful	−	Nissl staining unsatisfactory
4	M	39	Acute poliomyelitis	Doubtful	+	−	±	−	
5	F	30	Subarachnoid hæmorrhage	+	+	+	−	−

8	M	17	Acute poliomyelitis	+	−	−	−	−	

TABLE II—STRUCTURAL FEATURES IN TEMPORAL LOBES OF NON-EPILEPTIC MENTALLY DEFECTIVE PATIENTS

Case no.	Sex	Age (yr.)	Clinical features	Meningeal fibrosis	Subpial gliosis	Cortical atrophy	Gliosis of white matter	Sclerosis of Ammon's horn	Chief additional features
9	M	25	Congenital mental defect feeble-mindedness diabetes	+	++	±	−	±	
10	M	1	Unclassified congenital idiocy	−	+	+	+	+	Generalised cortical atrophy
11	M	14	Mongolism imbecility	+	+	±	+	−	
12	M	2	Microcephalic idiocy terminal meningitis	+	+	+	+	−	
13	F	3	Slight microcephaly patent foramen ovale idiocy	+	+	+	+	−	Marked disorientation of nerve cells
14	M	7	Moderate microcephalic idiocy	−	±	±	−	−	
15	M	11	Gargoylism	+	+++	++	+++	−	Distension and ballooning of nerve-cells meningeal cellular infiltration
16	M	60	Unclassified feeble-mindedness	Doubtful	Doubtful	+	Doubtful	−	Staining unsatisfactory
17	F	2	Microcephalic imbecility	++	++	Doubtful	+	−	Increase of capillaries in white matter Nissl staining unsatisfactory
18	M	7	Idiocy possibly caused by Rh incompatibility	+	++	±	+	−	
19	M	7	Obstructive hydrocephalus	++	+++	++	++	±	Ventricular granulations
20	F	21	Microcephalic imbecility with diplegia	+	++	+	+	+	Marked neuronophagia
21	M	[illegible]	Mongolian imbecility	Doubtful	Doubtful	+	Doubtful	−	Staining unsatisfactory
22	M	[illegible]	Idiocy possibly caused by Rh incompatibility		++	++	+	+	Status marmoratus of thalamus
23	M	4	Slight microcephaly athetosis imbecility	−	Doubtful	+	+	−	
24	M	1½	Microcephalic idiocy		+	+	+	Doubtful	Pachygyria and microgyria
25	F	4	Mongolian imbecility	Doubtful	+	+	+	−	Status spongiosus of white matter
26	F	6	Hydrocephalic idiocy	+	±		+	−	
27	M	5	Unclassified imbecility		++	+	+	−	
28	F	5	Imbecility following tuberculous meningitis	++	+	++	+	+	
29	M	4	Mongolian feeble-mindedness	−	Doubtful	+	Doubtful	−	

Indefinite results due to unsuccessful staining are marked as doubtful, results doubtful in spite of satisfactory staining as ±, and positive ones +, ++ and +++ in order of severity.

lesions may be expected elsewhere in the brain when either type is detected in a single temporal lobe, since, except for tumours, they were all represented here and were always widely scattered

Discussion

This study throws doubt on the significance of certain lesions found on biopsy and alleged to account for most cases of "temporal lobe" epilepsy Such diffuse and microscopic abnormalities occur in the temporal lobes of patients with no such clinical picture, moreover, their detection is unreliable

The study also indicates that, in mental defectives with epilepsy, brain lesions are neither peculiar nor confined to the temporal lobes The material further suggests that, in "temporal lobe" epilepsy, lesions when present in one temporal lobe will be accompanied by others elsewhere in the brain in many cases

The material in this report is small, and further observations are clearly necessary to determine what constitutes normal variation, and what these structural abnormalities signify It is possible, however, to reach some preliminary conclusions

It has long been known that certain cases of focal epilepsy are associated with lesions, usually circumscribed, such as tumours and scars, in one of the temporal lobes The current extension of this concept to a large number of other cases seems to lack sufficient morphological evidence It is still particularly necessary in any given case to exclude lesions outside the affected temporal lobe, even where an abnormality in the latter is beyond question In most cases the clinical relevance of whatever deviations are seen under the microscope has yet to be established The present study suggests that their importance may be slight

I appreciate, of course, that the modern concept of "temporal lobe" epilepsy rests not on morbid anatomy alone but also largely on the reported value of temporal lobectomy But the findings recorded here indicate the need for careful reconsideration of the basis of clinical assumptions

Summary

The increase in temporal lobectomy is based partly on the examination of resected tissue, abnormalities being recorded in every published case, but the significance of such abnormalities is doubtful

The microscopical appearances forming the sole abnormality in most of the published cases are not peculiar to "temporal lobe" epilepsy They depend on subjective assessment and inconsistent methods of staining, and, where slight, are not always pathological

Whenever indisputable abnormality exists in one temporal lobe it is likely to be associated with lesions elsewhere in the brain and, possibly, in the opposite temporal lobe Usually, therefore, disease will not be eradicated by removal of a single temporal lobe

The presence of certain lesions in the temporal lobes does not prove their responsibility for epilepsy or other symptoms

Further observation to determine what constitutes normal histological variation is necessary before importance is attached to certain microscopical findings

I am greatly indebted to my lay and medical colleagues at the Fountain Hospital for their help, access to case records, and discussion of this report

When the adrenal glands are healthy, the administration of corticotrophin is usually followed by a fall in the eosinophil-count in the peripheral blood (Thorn et al 1948, Forsham et al 1948) Since this eosinopenia does not develop in addisonian patients but can be produced by giving both normal and adrenalectomised people pure adrenocortical hormones, there is good evidence that it is related to increased adrenocortical activity This relationship has been confirmed by the simultaneous changes in the eosinophil-count and in the level of adrenocortical hormones in the blood after the administration of corticotrophin (Nelson et al 1952, Gemzell and Franksson 1953, Hunter et al 1955)

The injection of adrenaline may also cause eosinopenia in man and laboratory animals This response likewise has been attributed to increased adrenocortical activity because it is not observed to the same degree either in untreated addisonian patients or in adrenalectomised mice (Laragh and Almy 1948, Recant et al 1950, Speirs and Meyer 1949, Bisso 1953) Recant et al (1950) observed a mean change of –62% (range from –40% to –80%) in the eosinophil count of healthy people after an injection of 0 3 mg of adrenaline, whereas in 11 patients with untreated Addison's disease the mean change was only –21% (range from +20% to –44%)

Increased amounts of adrenocortical hormones have been reported in the venous blood of the adrenal glands of dogs and cats after the infusion of adrenaline, and in rats adrenaline depletes the ascorbic acid and cholesterol of the adrenal glands (a response taken to indicate increased adrenocortical secretion) (Vogt 1944, Long and Fry 1945, Pickford and Vogt 1951)

These changes do not take place in hypophysectomised animals, hence it has been suggested that adrenaline enhances adrenocortical activity indirectly by stimulating the hypothalamus and thence the pituitary gland to secrete increased amounts of corticotrophin These observations form the basis for the adrenaline test of pituitary-adrenal function proposed by Recant et al (1950)

The validity of this concept has been called in question since the observation by Muehrcke et al (1952) that, whereas in untreated addisonian patients the injection of adrenaline does not cause significant eosinopenia, it produced a significant fall in the eosinophil-count of 36–78% in 5 adrenalectomised patients receiving constant cortisone maintenance therapy, although the administration of corticotrophin induced no change in the eosinophil-count This suggested that the presence of adrenocortical hormones was necessary for adrenaline to cause a significant eosinopenia, but that the eosinopenia was not directly due to increased adrenocortical activity

The study reported here was undertaken to find out whether the eosinopenia following the administration of adrenaline was due to increased adrenocortical secretion judged by direct measurement of the plasma level of adrenocortical steroids and by comparing the response

to adrenaline with those to single intravenous injections of corticotrophin

Material and Methods

Corticotrophin 30 units dissolved in 10 ml of saline solution was injected intravenously over 5 minutes into 5 people, and adrenaline 0·3–0·5 mg subcutaneously into 16 people of whom most were healthy colleagues but a few were convalescent patients These observations were controlled by eosinophil-counts after an injection of saline solution in 12 people in many of whom eosinophil-counts had previously been made after the injection of adrenaline

All the observations were made between 10 A.M and 4 P.M The eosinophils in peripheral blood obtained from a finger and stained by Randolph's method, were counted hourly for 6 hours by one observer (J D H) For each count two leucocyte counting pipettes were used, and two Fuchs Rosenthal counting-chambers were filled from each.

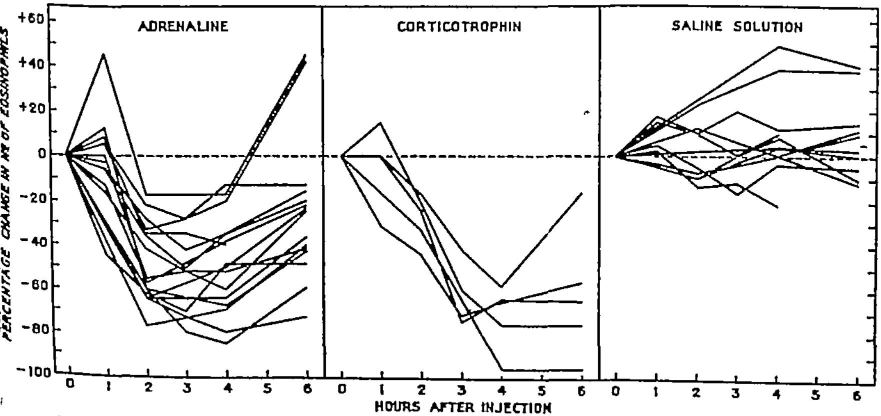
The plasma level of 17 hydroxycorticosteroids was measured by the method of Nelson and Samuels (1952) modified by Bayliss and Steinbeck (1953) The accuracy of this method is such that a rise or a fall of 4 µg per 100 ml of plasma can be considered a significant change.

Results

Adrenaline

The results are shown in table I and the accompanying figure In most of the people adrenaline produced pallor, tremor and palpitations In all of them the eosinophil count fell to a minimum at 2–4 hours after the injection but to widely different amounts ranging from −17% to −84% (mean −55%) The mean falls 2 3 and 4 hours after the injection of adrenaline were 48%, 50%, and 47% respectively

The plasma levels of 17 hydroxycorticosteroids, which are known to cause eosinopenia were determined in multiple samples of blood taken during the first 30 minutes after the injection Particular attention was paid to this time because the observations of Kelley et al (1952) Sandberg et al (1953) and Ly et al (1954) published while our investigation was in progress had not shown any increase in plasma-steroid levels 1–4 hours after the injection of adrenaline, and because previous studies had shown that after an intramuscular injection of corticotrophin the peak of the plasma-steroid level was about 2 hours before the greatest fall in the eosinophil-count (Nelson et al 1952, Gemzell and



Percentage changes in numbers of eosinophils after injection of (1) adrenaline (2) corticotrophin, and (3) saline solution

TABLE II—PLASMA LEVELS OF 17-HYDROXYCORTICOSTEROIDS AND EOSINOPHIL-COUNTS AFTER A SINGLE INTRAVENOUS INJECTION OF 30 UNITS OF CORTICOTROPHIN

Case no	Sex	Age (yr)	Hr after injection							Eosinophil-count					
			0	1/4	1/2	1	2	3	4	Initial count (per c mm)	Percentage change (hr after injection)				
			Plasma level of 17 hydroxycorticosteroids (µg per 100 ml)								1	2	3	4	6
17	F	30	18	15		28	28			112		−33		−95	[illegible]
18	M	36	10	18	20	22	37	24	11	50	0	−24	−74	−64	[illegible]
19	M	52	13	16	38	23	30	23	20	144	−31	−44	−72	−65	[illegible]
20	M	58	6	17	13	25	30	26	19	106	0	−17	−41	−59	[illegible]
21	M	45								125	+15	−20	−60	−75	[illegible]
										Mean	−4	−28	−62	−71	−6

Franksson 1953, Hunter et al 1955) Hence it was argued that if the eosinopenia, which is severest about 2 hours after the injection of adrenaline, were due to increased adrenocortical activity the plasma steroid level would be expected to rise within the first few minutes after the injection

No consistent change in the plasma level of 17 hydroxycorticosteroids was observed In case 1 the eosinophil-count fell by 70% and the plasma-steroid level from 17 µg to 9 µg per 100 ml In 6 people (cases 2–7) the plasma steroid level rose by more than 4 µg per 100 ml, and in each instance there was eosinopenia, the greatest change in the eosinophil-count ranging from −28% to −84% (mean −63%) In contrast 9 people (cases 8–16) showed a change in the eosinophil-count ranging from −17% to −79% (mean −48%) without any change in the plasma-steroid level beyond 4 µg per 100 ml

For example, case 14, whose eosinophil count fell by 51%, had strikingly little variation in the plasma steroid levels The mean maximal fall in the eosinophil-count was not statistically greater in the people whose plasma-steroid level rose than in those in whom it did not change ($t=1\ 245$)

Control Observations

No consistent changes in the eosinophil count were observed in the 12 controls over the 6 hours' observation, and in none did the eosinophil count fall by more than 22% (see figure)

Intravenous Corticotrophin

The results are shown in table II and in the figure The greatest fall in the eosinophil count took place 3–4 hours after the injection, and the mean falls at 2, 3, and 4 hours were 28%, 62%, and 71% respectively The plasma steroid level rose significantly 1 hour after the corticotrophin had been given, and in some people it rose within 15–30 minutes

Discussion

These results show that the fall in the eosinophil count induced by adrenaline is unrelated to increased adrenocortical activity, because the degree of eosinopenia was the same whether or not the plasma steroid level rose Furthermore the *greatest fall in the eosinophil count* did not take place until 3–4 hours after a single intravenous injection of corticotrophin, whereas *it took place at least an hour earlier after an injection of adrenaline* If adrenaline caused eosinopenia by releasing corticotrophin, one would expect the eosinopenia after the injection of corticotrophin to reach its maximum as soon as or sooner than, after the injection of adrenaline The injection of adrenaline was not followed by a detectable rise in the plasma level of 17 hydroxycorticosteroids in 10 of 16 people The rise in the plasma steroid level in 5 was much less than that usually observed after the injection of corticotrophin Whether the increased adrenocortical activity observed in these 5 people was directly related to adrenaline or to some other factor, such as emotion, must remain undecided, but in view of the findings of Sandberg et al (1953) it is clear that in man adrenaline does not necessarily cause increased secretion of adrenocortical hormones

On the available evidence it seems that the presence, rather than an increase, of adrenocortical hormones is necessary for adrenaline to lower the eosinophil count more than 50% (Muehrcke et al 1952, Henry et al 1953) But, even *in the presence of normal plasma*-steroid levels, 5 of our subjects did not show an eosinopenia *of this degree, and Fisher and Fisher* (1951) have also emphasised that healthy people often have no significant eosinopenia after the administration of adrenaline Therefore, if a person's eosinophil-count is lowered more than 50% by the administration of adrenaline, *adrenocortical* function is probably normal If, on the other hand, it is not lowered so much, no conclusions can be drawn Furthermore in other circumstances—e g, after severe burns and after trauma—the eosinophil count cannot be used as a valid index of adrenocortical function

Summary

Adrenaline causes a variable degree of eosinopenia which is maximal 2–4 hours after the injection, whereas after the intravenous injection of corticotrophin the eosinopenia is maximal after a delay of 4 hours

The eosinopenia after the injection of adrenaline is unrelated to any rise in the plasma level of 17 hydroxycorticosteroids

These observations suggest that, in man, adrenaline does not cause increased adrenocortical secretion

CORTISONE, CORTICOTROPHIN, AND INFECTION

A. G. SHAPER
M.B. Cape Town, D.T.M. & H.

A. DYSON
M.B. Lpool

MEDICAL REGISTRARS, CLATTERBRIDGE HOSPITAL, BEBINGTON, CHESHIRE

THE tendency for cortisone and corticotrophin to enhance bacterial infections has been noted as one of the most important complications of therapy with these hormones.

Coste et al. (1951) estimated that 10% of patients so treated developed infective complications, especially staphylococcal abscesses at the site of injection and acute pneumonia. Dubois-Ferrière (1951) described a case of staphylococcal septicæmia in a patient under treatment with cortisone, and Page (1954) reports two cases of fulminating pneumonia in patients treated with corticotrophin and with cortisone.

In the following two cases fatal staphylococcal septicæmia supervened.

Case reports

Case 1.—A woman was diagnosed as having acute rheumatoid arthritis in 1946 at the age of 30. While on treatment with Myocrisin she developed at the site of injection a staphylococcal abscess which required incision. In June, 1954, she was admitted for two months with an exacerbation of her arthritis and a mild erythematous rash over the forehead and malar regions. She had intermittent pyrexia and showed no clinical response to treatment with mepacrine and chloroquine. Her intermittent pyrexia persisted until October, 1954, when she was readmitted with active arthritis and much loss of weight. On the basis of her skin lesions and the course of her illness, as well as laboratory investigations, disseminated lupus erythematosus was diagnosed. From the time of her readmission in October, 1954, the intermittent pyrexia continued and on Nov. 4 her temperature was 101·4°F. Examination revealed rhonchi and occasional râles over both lung fields, and treatment with crystalline penicillin 500 000 units six-hourly was started and continued until Nov. 7.

Cortisone Therapy.—On Nov. 5 concomitant therapy with cortisone 200 mg. daily was begun. Her general condition improved rapidly, and her temperature became normal for the first time in three weeks and remained so for the following eight days. On the ninth day of cortisone treatment (Nov. 13) she spent the morning walking about the ward. At 2.30 P.M. her temperature was found to be 103·8°F and at 6 P.M. it was 102·2°F. She vomited a little on one occasion but otherwise felt well. Examination revealed no physical signs of disease. At 10 P.M. her temperature was 103°F and pulse-rate 150. At 6 A.M. next morning she was found comatose with temperature 103°F and blood-pressure 100/50 mm. Hg and unresponsive to stimuli. She had no signs of meningeal irritation, and all her limbs were equally flaccid, with normal plantar responses. She was given crystalline penicillin 1 000 000 units immediately and 500 000 units six-hourly thereafter. By 10 A.M. her respirations had become stertorous, her blood-pressure had fallen to 70/40 mm. Hg, and there was slight neck rigidity. Lumbar puncture revealed a turbid fluid under normal pressure and containing 1200 cells per c.mm., mainly polymorphs, total protein 120 mg. per 100 ml., and sugar 50 mg. per 100 ml., and a stained film showed polymorphs but no organisms. There was no growth after twenty-four hours' culture. The patient was given intrathecal penicillin 10 000 units. Her blood-pressure continued to fall, and an infusion with noradrenaline in 5% glucose-saline solution was started, which produced a temporary rise of blood-pressure, but her condition deteriorated and she died at 10.45 P.M.

Necropsy Findings.—The brain showed no gross changes beyond slight congestion of the meninges. The liver was considerably enlarged (72 oz.) and showed fatty change. The spleen was enlarged (13 oz.) and very soft. Both kidneys were of normal size; on their cortical surfaces were numerous small petechial hæmorrhages and multiple small abscesses. Abscesses were also found in the substance of the kidney, from which a penicillin-sensitive *Staphylococcus aureus* was grown. Death was due to staphylococcal septicæmia.

Case 2.—A man aged 50 was admitted in September, 1953, with primary exfoliative dermatitis. Cortisone therapy was instituted, and he was maintained on an average dose of 100 mg. daily. In March, 1954, corticotrophin therapy was started in addition to the cortisone, an average of 75 mg. of corticotrophin and 50 mg. of cortisone being given daily. This dosage was varied from time to time, and by November, 1954, the patient was receiving 50 mg. of corticotrophin and 50 mg. of cortisone daily, and his skin was improving. From his admission until November, 1954, his condition remained fairly satisfactory, and he was ambulant and complained only of cutaneous irritation. In March, 1954, he had developed a typical moon facies, which persisted. On Nov. 19 he developed over his right elbow a superficial abscess which discharged spontaneously and healed. A small inflammatory nodule on the dorsum of his left hand also cleared spontaneously. On the evening of Nov. 26, while at rest in bed, he developed severe precordial pain which radiated down both arms and was associated with considerable dyspnœa. The lung fields were normal on examination, heart sounds were faint, and heart size could not be estimated clinically. Myocardial infarction was diagnosed and was confirmed by electrocardiography. In view of the skin condition treatment with cortisone and corticotrophin was continued. Two days later the patient became more dyspnœic and slightly confused. He was found to have auricular fibrillation and received digitalis, which had little effect on the heart-rate. The dyspnœa persisted for several days, but there was no further chest pain, and the patient was conscious and able to eat his meals. On Dec. 3 his condition deteriorated rapidly, and in three or four hours he became semiconscious. Towards evening his temperature rose to 102°F, and he was given crystalline penicillin 500 000 units six-hourly; he developed Cheyne-Stokes respiration and died next day.

Necropsy Findings.—Meningitis was present, with a collection of thick yellow pus covering the undersurface of the brain. The pericardium was grossly distended by thin yellow pus, and the left ventricle was considerably hypertrophied. In the interventricular septum were much scarring and fibrosis associated with hæmorrhage into the septum. Two small abscesses were found in the myocardium. Both kidneys were of normal size and contained several small abscesses in their substance. *Staph. aureus* was grown from the pus in the pericardial cavity and from the myocardial abscesses. Death was due to staphylococcal septicæmia.

Discussion

Experiments on animals have given the impression that uncontrolled infections following treatment with either cortisone or corticotrophin are a result of overdosage; that this is not necessarily so is shown by one of the cases described by Page (1954) which had been treated with 20 mg. of corticotrophin gel for seven days, and by the present case 1, in which 200 mg. of cortisone was given daily for nine days.

The causes of infections in patients treated with either corticotrophin or cortisone are not clear; but whatever the primary cause, the result is a disturbance of the host-parasite relationship in favour of the parasite.

The practical problems are those of prophylaxis, early diagnosis, and suitable treatment. The routine administration of a broad-spectrum antibiotic as a prophylactic does not recommend itself to most physicians, and regular weekly diagnostic blood-cultures will only give a false sense of security. Regular clinical examinations are most important in the search for symptomless infections, and any clinical signs of disease should be fully investigated by radiography, blood-counts, and blood-cultures.

There is both experimental and clinical evidence that in patients under treatment with either corticotrophin or cortisone antibiotics may become relatively ineffective. The reason for the need for larger doses of antibiotics than usual may, however, be a consequence of late diagnosis due to the masking of symptoms and not of some intrinsic effect of cortisone on antibiotics.

Consideration should be given to the use of somatotrophic hormone (growth factor) in the prevention the treatment of infections in patients under treatment with either corticotrophin or cortisone Selye (1951) considered on theoretical grounds that this factor might act as an antagonist to the infection-spreading action of corticotrophin and cortisone, and his experiments on animals have shown that this action can be completely prevented by suitable doses of purified somatotrophic hormone Lewis (1953) reports that this work has been confirmed by H J Robinson The somatotrophic hormone and preparations containing several principles of the anterior lobe of the pituitary gland in combination with somatotrophic hormone are available commercially, and it should be possible for centres treating large numbers of patients with corticotrophin and cortisone to make a controlled investigation into this possibility

Summary

Two cases of staphylococcal septicæmia complicating treatment with corticotrophin and cortisone are described

The use of somatotrophic hormone in prophylaxis and treatment of such infections is suggested

We wish to thank Dr F J Zacharias and Dr D G Freshwater, under whose care these cases were admitted, Dr M. W W Wood and Dr Zacharias for their encouragement and advice in the preparation of this paper, and Dr H MacLean for the necropsy reports

WHEN we found that arterial grafts deteriorated when kept for three or four weeks in the solution of Gross et al (1949), we carefully studied the method of freeze drying described by Eastcott et al (1954) of St Mary's Hospital London, because it originated from the first active artery bank to be established in this country

Our previous experience over the past eleven years with freeze-drying of bacterial cultures has enabled us to simplify the technique of the St Mary's Hospital team further to a single stage operation

Apparatus

and Rubber Stopper with s (Tube Head)—The tube

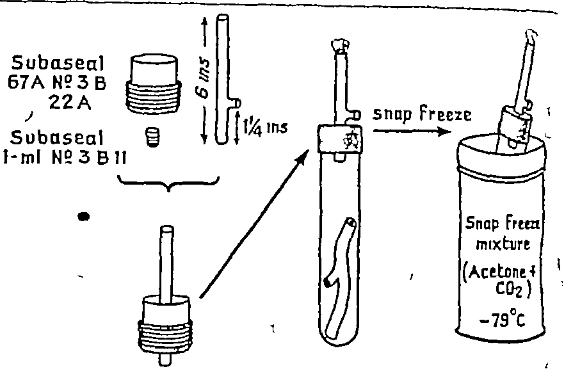

Fig 1—Drying tube and apparatus for snap-freezing

for the artery is of 'Pyrex' glass 25 cm long with an inside diameter of 32 ± 1 mm It is sterilised, plugged with cotton wool, and, when autoclaved, is ready for the surgeon to collect the arteries The construction of a rubber stopper carrying a suitable smaller pyrex glass tube to allow evacuation of the large pyrex tube, permanent sealing after completion of the freeze drying, and a simple sterile method of reconstituting the dried artery is shown in fig 1 The rubber stopper used is a 3 B 22A type 'Subaseal' artery graft closure turnover 67A with a central perforation, the broader uppermost flange of this bung rides on the rim of the large pyrex tube thus preventing the bung from being sucked inside by the high vacuum present at the end of the freeze drying A side-arm is blown on to a length of narrow pyrex glass tubing (15 cm long with an outside diameter of 9 mm) about 3 cm from one end of this smaller tube, and the diameter of the short side arm is standardised to give an airtight fit with a small rubber bung, which is either a standard subaseal 3.B.11 type turnover (1 ml) vial closure or a subaseal turnover *closure 13H B.H drab The short end of the 15 cm* narrow pyrex tube—now a T tube—is inserted into the central perforation of the large rubber stopper, and the opposite end of the tube is closed either with a cotton wool plug or a standard subaseal 3 B 16 utility cover cap 9 All these parts assembled form the "head" of the tube containing the graft, tube and head together form the "drying tube." The complete head is wrapped up in lint and sterilised by autoclaving at 15 lb pressure for 30 minutes The flange of the sterile head should be moistened with a few drops sterile liquid paraffin to ease insertion into the mouth of the pyrex tube containing the artery

Vacuum Equipment—The essential parts of the equipm —vacuum pump, moisture trap, and manifold for the dr tubes—are shown in fig 2 The pyrex glass manifold connected in series by pressure tubing with a moisture tr and a single stage rotary vacuum pump (Edwards 1 S.15 protected by a phosphorus pentoxide trap The manif has an outside diameter of 18 mm and seven side arms 30 mm long, each having an outside diameter of 15 mm To six the side arms a pyrex glass high vacuum stopcock with 10 mm. bore is connected by rubber pressure tubing, and these are attached the drying tubes The seventh side-arm is permanently connected to a Pirani gauge head The high vacuum stopcocks enable each drying tube to be individu connected to the apparatus and sealed off from it with accidentally breaking the vacuum of the whole system.

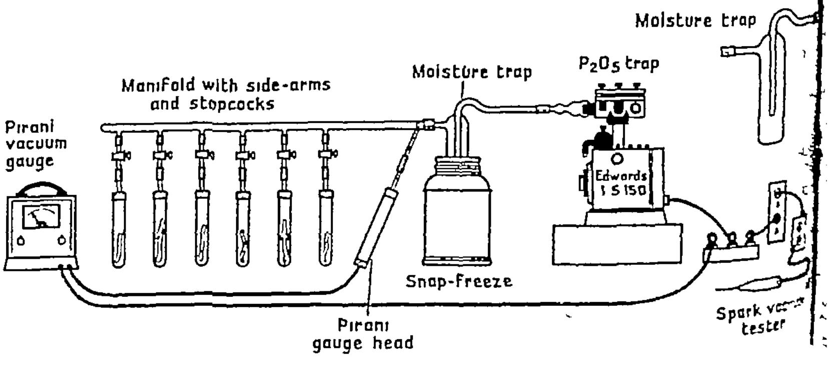

Fig 2—Vacuum equipment for freeze-drying

Method

Collection of Arteries—People aged less than 30 who have died from either trauma or poisoning are selected within six hours of death Extensive patchy atheroma may be found even at this age, and only arteries which are regular in their consistence to palpation when empty are used for freeze-drying if patches of atheroma are felt, the arteries are stored in Gross's solution An aseptic technique is used to remove the whole aorta and the external iliac and femoral arteries as far as the origin of the popliteal arteries by an extraperitoneal and transpleural approach The abdominal aorta is divided at the level of the renal arteries and the external iliac arteries are divided at the origin of the femoral arteries the resulting four pieces of tissue are put in four sterile pyrex tubes whose ends are closed with sterile cotton wool. The tubes are taken to the department of bacteriology at once and freeze-drying started, or else they are stored overnight in a refrigerator whose temperature is maintained at +4°C

Sterilisation.—As an additional precaution the arteries are sterilised on arrival at the laboratory by treatment with a 1% solution (v/v) of liquid ethylene oxide (B D H) Since ethylene oxide boils at 10·7 C and is explosive and rather toxic it must be stored in a refrigerator and handled in a cold storage room at +4 C with chilled syringes and needles. Each artery is covered with a measured quantity of sterile physiological saline solution at +4 C and for the sterile cotton wool plug is substituted a well fitting sterile rubber stopper Sufficient ethylene oxide is next added to give a 1% solution and the tube is inverted several times over the rubber stopper to ensure uniform solution of the ethylene oxide The tube is left at +4°C for one to two hours the rubber stopper is replaced by a sterile cotton wool plug, and the tube is placed in a fume cupboard at room temperature overnight to allow the ethylene oxide to vaporate The saline solution is next poured off under aseptic recautions the cotton wool plug is replaced in the mouth of ho tube and the whole is inverted in a refrigerator at +4 C o allow all residual moisture to drain into the cotton wool lug Small segments of the artery are next cut off under eptic conditions for aerobic and anaerobic sterility tests.

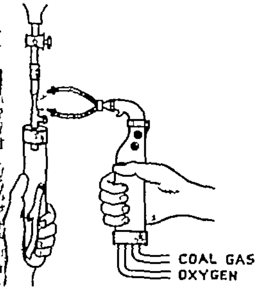

Fig. 3—Sealing of drying-tube in vacuo.

Snap-freezing—The tube containing the artery is fitted with ho bung with attachments and immersed in a mixture of olid carbon dioxide and acetone in a quart-size Thermos ar for 15 minutes (fig 1) The artery is then ready for mmediate drying or it can be kept in solid carbon dioxide t −79°C until it is convenient to dry it

Freeze-drying—Each stopcock is kept closed with the acuum pump running until the drying tube is connected o it the stopcock is next opened to obtain a high vacuum a rapidly as possible; sublimation of ice with consequent all of temperature prevents softening of the frozen artery he Pirani gauge shows the vacuum obtained and the amount f residual moisture at any given stage of the drying because o long as sublimation from the artery takes place water apour in the system will prevent the pressure from reaching ts minimum. When the limit of the vacuum pump under hese conditions is reached (about 0·01 mm Hg in the case of dwards Speedivac 1S 150) it is assumed that no more ublimation will take place and that drying is complete but o be on the safe side the vacuum pump is allowed to run for nother one to two hours, during which the Pirani gauge hould remain steady

Sealing in Vacuo—Immediately before the sealing of each rying tube its vacuum stopcock is closed to prevent accidental ontamination of the other tubes still attached to the manifold. The 15-cm glass tube of the head is next sealed above its side arm with a Chance's Flame Master cross fire burner using coal gas and oxygen (fig 3) and cautiously tested for high vacuum with a spark tester Care should be taken that the spark does not cause a leak in the glass The sealed head of the tube is next protected by a Viskap seal which comes well down the neck of the tube and a viskap sleeve with printed instructions for reconstitution of the grafting material is finally put round the body of the tube

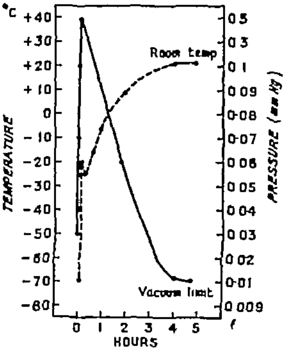

Fig 4—Relationship between temperature and vapour pressure within evacuating system during freeze-drying of a piece of femoral artery measuring 0·5 × 15·0 cm.

Reconstitution—The viskap seal is removed and the exposed surface of the subaseal turnover closure (1 ml vial) occluding the short side-arm is sterilised with either iodine or antiseptic triple dye A sterile blood transfusion giving set is attached by sterile rubber tubing to an infusion bottle containing saline solution with penicillin 100 units per ml and streptomycin 100 μg per ml If desired, heparin (2 ml per 100 ml) may be added to the reconstituting fluid The needle is next pushed through the side-arm closure Owing to the high vacuum the drying tube fills easily with the solution. Reconstitution is complete within twenty minutes.

Efficiency of Method

Technical—For a rough assessment of the temperature changes taking place during drying an alcohol thermometer was fitted in an airtight manner into one of the subaseal artery graft bungs the tip of the thermometer was manœuvred into the lumen of the frozen artery; and the temperature was read at regular intervals These readings, and those of the Pirani gauge which we used as an indication of the progress of drying were plotted against time Figs 4 and 5 show graphs obtained in this way during the drying of a piece of femoral artery measuring 0·5 × 15·0 cm and of a piece of abdominal aorta measuring 2·0 × 15·0 cm The graph obtained by processing a main arterial tree—e.g thoracic aorta abdominal aorta with both iliac arteries and the two femoral arteries—differs very little from that obtained with the 15-cm piece of aorta. The curves, as may be expected are flatter when large pieces of tissue are dried It takes less than five hours to dry completely one femoral artery twelve to thirteen hours to dry a piece of aorta 15 cm

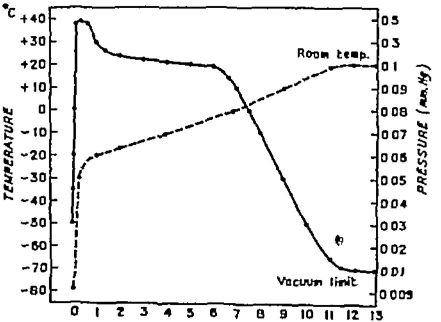

Fig 5—Same relationship as in fig 4 during freeze-drying of a piece of aorta measuring 2·0 × 15·0 cm.

long, and fourteen to fifteen hours to dry an arterial tree in one operation The actual temperature of the drying arteries is probably a little lower than the readings obtained, owing to the error introduced by external conduction of heat along the inserted thermometer, but absolutely accurate measurement of the temperature was thought to be less important than a general impression of the efficiency of the system, which is well demonstrated by the graphs The freezing mixture in the thermos container surrounding the moisture trap remains at –79°C for more than twenty-four hours, it is therefore possible to continue the drying overnight without any attention if it is not completed by the end of a working day

Bacteriological —Sterility tests are made aerobically in nutrient broth and anaerobically in Robertson's chopped meat broth, these media, inoculated with small segments of artery, are incubated for five days These and all other manipulations which require exposure of the artery are done inside an ultraviolet hood as used in virus and tissue culture work Thus contamination is excluded as much as possible So far only once has a femoral artery proved to be not sterile owing to having touched the outside of the large pyrex tube accidentally when samples were taken for sterility tests

Clinical —The reconstituted material is easy to handle, and the patient's clinical progress after the grafting of an aortic bifurcation prepared in this way is just as good as after that of a graft stored in Gross's solution

Discussion

The method of freeze-drying arterial grafts described by Eastcott et al (1954) does away with the necessity for keeping the grafts at low temperatures during most of the process, and with increasing the temperature subsequently to eliminate residual moisture, as has been necessary hitherto for satisfactory freeze drying of tissues' Their method, though simpler than those used by Marrangoni and Cecchini (1951) and Hufnagel (1954), consists of three stages (1) primary drying in vacuo of frozen arteries, (2) release of the vacuum, and secondary drying over phosphorus pentoxide, and (3) secondary evacuation and sealing in vacuo with 'Picien' high-vacuum wax after perforation of the rubber stopper with an aspiration needle

By the use of a special but simple closure head for the tubes in which the material is dried, of a pyrex-glass manifold with high-vacuum stopcocks between its side arms and the drying-tubes, and by the insertion of a deep cooled moisture-trap between the vacuum pump and the manifold, the process has been reduced to a single operation

Sterilisation with 1% ethylene oxide is not essential and can be omitted Though it has a moderate bleaching effect, ethylene oxide does not affect the elastic quality of the arterial wall We hope that ethylene oxide treatment will eventually permit us to dispense with strict aseptic precautions during collection, as advocated by Hufnagel (1954) This may ease the difficult task of finding suitable donor material, indeed Hufnagel states that ethylene oxide treatment renders heterologous arterial grafts acceptable to recipients

Eastcott et al (1954) state that fatty lesions in an atheromatous plaque invalidate the freeze-drying, so we use only grafts which are not atheromatous—i e, in which no thickenings can be felt, which is indeed a coarse method Atheromatous grafts can be kept indefinitely under deep freeze conditions at –79°C or stored for three or four weeks in Gross's solution with more safety The point is well illustrated by histological examinations made by Dr T W Sutherland on an aorta from a donor aged 39 A section cut before processing showed no abnormality a section cut after treatment with ethylene oxide showed very slight atheroma with a looser texture of the intima, and a section cut after reconstitution showed a still looser texture and prominent disrupted patches presumably due to overstretching of the intima over fatty deposits during drying It remains to be determined whether freeze dried grafts with slight atheromatous infiltrations might not be used successfully

The cost of the complete equipment, excluding rubber bungs and pyrex tubing, is about £130 One 25 cm pyrex tube costs 3*s* 9*d*, and one special rubber bung fitting into it about 5*s*., but both these parts can be used again many times, thus making a saving on the rubber bung compared with the method of Eastcott et al (1954) because they cannot use their perforated bung a second time

Summary

By the use of a special but simple closure head for the tubes in which the graft is dried, the insertion of a deep-cooled moisture trap between the vacuum pump and the manifold, and the provision of high vacuum stopcocks between the manifold and the drying tubes, arterial grafts may be freeze dried in a single operation in five to fifteen hours Once the freeze drying process has been started, the apparatus requires no further attention until sealing

The arteries are sterilised with a 1% solution of liquid ethylene oxide in saline solution Special precautions are required for handling this substance

We wish to thank Dr T W Sutherland and Dr W Goldie for providing us with post-mortem arteries for experimental purposes, Messrs Wm Freeman & Co (SubaSeal Works Barnsley) for making experimental types of rubber closures to our specifications and manufacturing the one finally chosen and Messrs Ralph Cuthbert (Huddersfield) for assisting us with the design of the pyrex glass parts of the earlier equipment We gratefully acknowledge a grant towards expenses given by the Board of Leeds United Hospitals One of us (K Z) is indebted to the Medical Research Council for a grant in aid of expenses

COMPRESSION OF THE ULNAR NERV AT THE WRIST BY A GANGLION

B L Mallett
M B Lond
FORMERLY NEUROLOGICAL REGISTRAR

K J Zilkha
M B Lond
FORMERLY NEUROLOGICAL HOUSE PHYSICIAN

GUY'S HOSPITAL, LONDON

TRAUMATIC neuritis of the ulnar nerve, giving rise t paralysis of the small muscles of the hand, has bee described for many years In most cases the site of th lesion is at the elbow More recently it has been recogni that the nerve may be damaged locally, at the wri or in the palm, and that then there is often a history occupational trauma

Anatomy

The ulnar nerve in the hand divides into a superfic division, which is often entirely sensory (or may cont motor fibres to the palmaris brevis muscle), and a de motor division, which at once disappears deeply betwe the abductor digiti minimi and the flexor digiti mini muscles It passes laterally behind the tendinous ori of the short flexor and perforates the opponens dig minimi muscle

Branches —The branch to the abductor muscle ar from the deep division just before the latter sinks into th hypothenar eminence The branch to the short flex muscle may arise at the same level, occasionally from common trunk Often it arises lower down, after th deep division has disappeared behind the short flex muscle Branches, occasionally two or three, to th opponens muscle arise as the deep division perforates th muscle (Hovelacque 1927)

Clinical Signs

Hunt (1908) described the clinical picture of involvement of the deep motor division with paralysis of all he small muscles supplied including the hypothenar roup The palmaris brevis muscle supplied by the uperficial division of the ulnar nerve was spared and here was no sensory loss

Seddon (1952) reported four cases of paralysis of the leep division of the ulnar nerve and cited twelve reviously published These differ from those described y Hunt (1908) in that in every case the hypothenar nuscles were spared Two patients gave a history of ulnar paræsthesiæ, one with pain but in no case was there any demonstrable sensory loss

Seddon notes that nearly all the patients were male half of them aged 40 or more the onset of the paralysis was either gradual or sudden and in almost all there was a clear history of trauma to the wrist or the palm, occasionally a single injury but more often repeated rauma connected with the patient s occupation Such ccupations included motor-cycling wire-cutting digging and the constant use of a leather knife held in the palm of the hand.

In one case, in an insurance agent with Dupuytren s contracture the palm was explored, but no constriction f fibrous tissue nor other compressing lesion was found

In five of the cases cited by Seddon an account of he subsequent progress is given (Russell and Whitty 947) These made a very good recovery in a few months cessation of the trauma held to be responsible

In the four cases observed by Seddon himself it was own for the first time that paralysis of the type escribed—i.e of all the small muscles supplied by the nar nerve excluding the hypothenar muscles and the almaris brevis muscle, and without sensory loss—may due to local remediable mechanical compression

In one of his cases there was tenderness medial to the ok of the hamate bone and in another crepitus on essure over the pisiform bone The latter also had pain d paræsthesiæ in the fourth and fifth digits

Seddon explored the wrists of all four In each he nd a small ganglion emerging from the palmar aspect a carpal joint and compressing the motor division the ulnar nerve distal to the branches supplying the othenar muscles. His patients made an excellent overy in 7–16 months.

Seddon suggests that the onset of paralysis either dual or sudden may be correlated in some cases h either gradual or sudden formation or enlargement a ganglion by herniation of the triquetral hamate novial sac Further such a ganglion may possibly ink spontaneously causing remission of the paralysis

Three cases of ganglionic compression of the ulnar rve with sensory loss as well as motor involvement re described by Brooks (1952) forming a distinct nical group

Two were in women aged 19 and 70 and one in a man aged The onset in each case was gradual, and in only one was re a history of trauma a fall on the outstretched hand e patient complained of ulnar paræsthesiæ and two had ellings, one tender in front of the wrist

All three had paralysis of all the ulnar intrinsic muscles e hypothenar muscles are not specially mentioned) and sory loss in the ulnar territory In each case a ganglion s found compressing the main trunk of the ulnar nerve ximal to its bifurcation into superficial and deep divisions.

There was good recovery in all three but a recurrence of the nglion after seven years demanded a further operation in case.

The original clinical picture described by Hunt 908), of involvement of all the ulnar intrinsic muscles the hand with no sensory loss has apparently not en been observed

We have recently seen two patients who presented in it such a way

Case reports

Case 1—A banker, aged 48 was admitted to Guy's Hospital under the care of Sir Charles Symonds. For twenty years he had written while standing at a high desk resting on the ulnar side of his wrist In the three months before admission he began to complain successively of pain in the right palm dropping his pen and then obvious wasting of his right hand

On examination (January 1954) there was moderate wasting of the interosseous muscles and slight wasting of the hypothenar muscles, with severe weakness of finger adduction and abduction including the abductor digiti minimi muscle and moderate weakness of the flexor digiti minimi brevis muscle There was no sensory loss. Pressure on the ulnar side of the pisiform bone caused local pain Radiography of the wrist showed evidence of osteo arthritis.

At operation Mr Grant Massie F.R.C.S found a ganglion compressing the main trunk of the ulnar nerve just proximal to its bifurcation into superficial and deep divisions. The ganglion was removed

Follow up—Five months later there was almost complete return of muscle bulk in the interossei and hypothenar muscles Power was virtually normal.

Case 2—A university lecturer aged 58 was admitted to Guy s Hospital under the care of Sir Charles Symonds. While acting in a play he had suddenly to extend his right wrist and to supinate his forearm fully flinging a person across the stage After the fifth performance he had pain in the hypothenar eminence Thenceforward he noticed gradually progressive weakness of adduction of the right little finger weakness of the fingers in holding a pen and weakness of grip

On examination (March 1954) two months after the onset there were wasting and severe weakness of the interosseous muscles and moderate weakness of the abductor digiti minimi muscle There was no sensory loss Radiography showed early osteo arthritic changes

At operation a ganglion as large as a small pea compressing the main trunk of the ulnar nerve was removed by Mr Massie

Follow up—Five months later the patient noted some improvement He could write better Healing of the wound had been delayed by trauma and infection but was now complete There was still obvious wasting of the interosseous muscles, with severe weakness of adduction and moderate weakness of abduction of the fingers, including the fifth

Discussion

A ganglion in front of the wrist joint may cause paralysis of the hand by compression of the ulnar nerve either its main trunk before bifurcation or its deep motor division Clinically it may present in one of three ways (1) paralysis of all the small muscles of the hand of ulnar innervation, with sensory loss in the ulnar territory (2) a similar paralysis with no sensory loss, and (3) with no sensory loss and with sparing of the hypothenar muscles

Our cases represent the second group Both men were aged more than 40 in both the onset was gradual and there was a history of trauma—in case 1 a chronic occupational trauma in case 2 repeated sudden unusual strain of the wrist joint—and in both radiography showed osteo arthritis

In neither case was there any sensory loss although at operation a ganglion was found compressing the main trunk of the ulnar nerve

After removal of the ganglion improvement was considerable in case 1 and slight in case 2

Summary

Three clinical types of paralysis of the hand due to ulnar nerve lesion at the wrist are discussed

All three may be due to ganglionic compression

When the ganglion is removed recovery from the paralysis is satisfactory

We wish to thank Sir Charles Symonds for his help and permission to publish

PUBLISHED cases of paroxysmal myoglobinuria have been reviewed by Acheson and McAlpine (1953), Elek and Anderson (1953), and Spaet et al (1954)

The last named collected 17 previously published cases, including 5 associated with muscular dystrophy, Gunther's (1924) case, which was almost certainly due to dermatomyositis, and the insufficiently documented case mentioned by Millikan (1939) They also include de Langen's (1946) case, omitting to mention that here myoglobinuria was due to exertion to the point of collapse, followed by a beating with a rifle butt in a Nazi concentration camp It was evidently a case of traumatic myoglobinuria

Hitherto 15 cases of myoglobinuria not associated with another muscle disorder have been published Many of the reports lack clinical details, making it uncertain that no other muscle disease was present, and in many there was no proof that the urinary pigment was myoglobin Of these patients 9 survived with little or no disability, sometimes after several attacks (Hittmair 1925, Debré et al 1934, Huber et al 1938, Hed 1947, 1953 [4 cases], Elek and Anderson 1953, Spaet et al 1954) The patient reported here also survives

The remaining 5 of the 15 patients whose cases have been previously published died *in an attack* (Paul 1924, Bywaters and Dible 1943, Schaar et al 1949, Buchanan and Steiner 1951, Stokes 1953) Death may take place within a few days, perhaps owing to the release of shock-producing substances from damaged muscle (Green 1943, Bielschowsky and Green 1943, Eggleton 1944, Green et al 1949, but see Kovách et al 1952) Other factors are involvement of respiratory muscles, pulmonary infection, and renal damage The cause of the renal damage is obscure it is probably a lower-nephron nephrosis (Bywaters and Dible 1943, Perri and Gorini 1952)

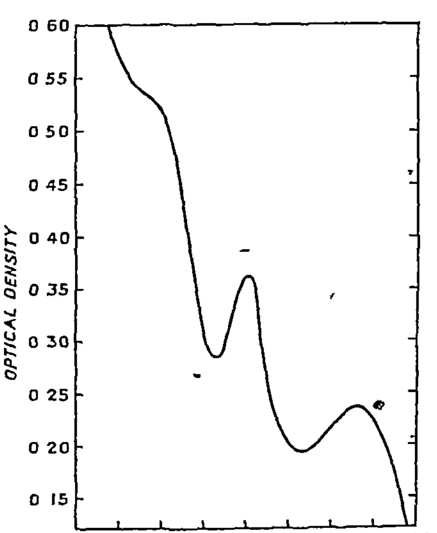

Fig 1—Optical-density curve of patient's urine cell depth 0 5 cm band width 4 mμ readings at 1 mμ intervals from 530 to 540 mμ from 575 mμ, and from 625 to 640 mμ elsewhere μ intervals.

Case-report

A girl, aged 10 years, complained of pains in both legs, and shortly afterwards abdominal pain and vomiting began There was abdominal and rectal tenderness Appendicectomy was done, and the appendix was found to be not inflamed On the day after the operation all the muscles becam painful and tender The urine was very dark brown an contained albumin, the guaiacum test was positive, but r red blood cells or porphyrin were present This fact, togeth with the history of muscle pains, suggested myoglobinur Examination with the Hartridge reversion spectrosco showed absorption bands judged to be at 583 and 635 m suggesting the presence of oxymyoglobin and a me compound

Progress —Four days after the onset the muscle pains ha gone, even though biopsy then showed gross changes Th patient recovered completely, and when last seen eight mon after the attack there had been no recurrence of sympto

Previous History —The patient was an adopted child an no family history was available At the age of 4 years sh had been admitted twice in one year to another hospital O the first occasion all that was found was "transient p teinuria" On the second occasion she had pains in the le and passed urine "like stout" She quickly recovered

Laboratory Investigations —Examination of the blo showed Hb 17 1 g per 100 ml, white cells 24,000 per c (polymorphs 92%), erythrocyte sedimentation rate 2 in 1st hr (Wintrobe), serum potassium (3 days after onset) 19 0 mg per 100 ml Lumbar puncture produced normal cerebrospinal fluid The serum-pseudocholinesterase level was within the normal range, hydrolysing 161 μ mols of acetylcholine bromide per ml per hr A glucose-tolerance test after the patient's recovery showed a normal curve with renal glycosuria Two days after the onset the 24 hr urinary output of creatine was 0 75 g creatinine 3 0 g, and of 17 ketosteroids 6 mg (normal 1 3-3 0 mg) The red cell fragility was moderately incre

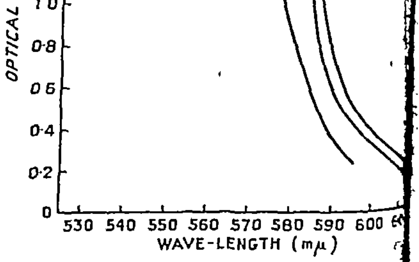

Fig 2—Optical-density curves of patient's urine myoglobin from human muscle (B) ; and globin (C), all converted to carboxy compo cell depth 1 cm ; band width 4 mμ, cur and B read at 1 mμ intervals from 535 to 5 and from 575 to 580 mμ curve C read at 1 intervals from 535 to 545 mμ and from 5 570 mμ readings elsewhere at 5 mμ interva

Percentage Saline Solution	*Percentage Hæmolys* *Patient*	*Healthy C*
0 55	0	0
0 52	6 5	1
0 50	18 0	2 5
0 48	39 0	9·0
0 44	86 0	51·0
0 42	96 6	76·0
0 40	100 0	86·0
0 30	100 0	100·0

Coombs's test, Ham's test for hæmolysis in acidified se Dacie's test for autohæmolysis on incubation, and Schumm for methæmalbumin were negative Reticulocytes were 1

Electrocardiography gave normal results, and el myography of several muscle groups twelve days after onset showed no abnormality

Spectroscopy of Urine —The patient's urine was exa in the Wright spectrophotometer Because of the spectrum in this instrument (20 cm between 400 and 700 and other features described elsewhere (Wright 1954) was no difficulty in taking readings at intervals of 1 Since the light absorption of normal urine increases fro red to the blue end of the spectrum, the beta band of ox globin shows in the present case only as an inflexion

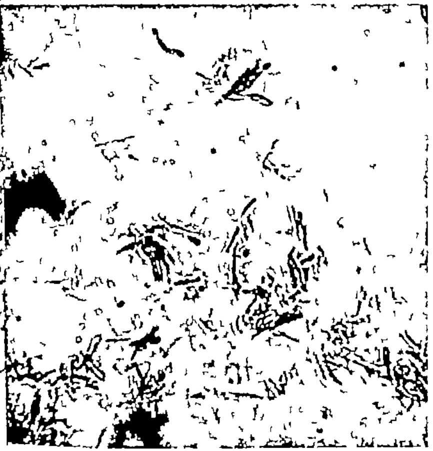

Fig 3—Crystals of metmyoglobin from patient's urine (×218)

urve at 540 mμ (fig 1) The alpha band of oxymyoglobin roduces a peak with a maximum at 580 mμ the peak at 0-632 mμ being that of metmyoglobin.

There are certain difficulties in the spectroscopic differentia on of oxymyoglobin and oxyhæmoglobin The alpha band axima are only 3–4 mμ apart and the beta band maxima -2 mμ apart Moreover exposure to air causes rapid oxidation metmyoglobin, with weakening of the alpha and beta nds and appearance of a non specific band at 630–633 mμ g 1) These difficulties are overcome by conversion of ymyoglobin and metmyoglobin to carboxymyoglobin. The pha-band maxima of carboxymyoglobin and carboxyhæmo obin are 10 mμ apart making their spectroscopic differentia on easy (fig 2)

Pigment	Position of Alpha-band Maximum Oxy Compound	 Carboxy Compound
moglobin	577 } 4 mμ apart	568 } 10 mμ apart
oglobin	581	578

Method (*after Blöck 1949*)—A spectroscope cell is almost led with the urine previously buffered to pH 8 and filtered al-gas is bubbled through it for 3–4 minutes a knife-point sodium hydrosulphite is added and the surface is covered ith liquid paraffin. Passage of coal gas is continued for other 3–4 minutes and the cell is covered with a lid The ition of the alpha band is then found with a reversion ectroscope, or the solution is compared with a solution of rboxyhæmoglobin in a comparison spectroscope Myoglobin s only a twenty fifth of the affinity of Hb for carbon onoxide and in contact with air is quickly converted to etmyoglobin If the cell is kept covered little change kes place for some hours

Estimation of Myoglobin.—We used Blörck's (1949) modifica n of de Duve's (1948) method to measure the myoglobin ntent of a biopsy specimen of one of the affected muscles her methods have been proposed by Shenk et al (1934) atson (1936) Beznák (1948) and Rossi Fanelli (1948) iefly the pigments are extracted from the muscle and nverted to carboxy compounds. Optical density is measured three wave-lengths, and the concentrations of myoglobin d Hb present are calculated from their respective extinction efficients Measurement of optical density after conversion pyridine hæmochromogen provides a check on the results e normal myoglobin content of human skeletal muscle is 3·0% of dry weight (Blörck 1949) In the present case ly 0·42% of myoglobin was present The results of measuring carboxy compounds and as pyridine hæmochromogen reed to within 4% The myoglobin content of the urine s about 1 mg per ml. or 1·5 g in the 24 hr output

Crystallisation—Methods for crystallising myoglobin from uscle are given by Theorell (1932) Bowen (1948) Rossi anelli (1949) Rees (1949) and Lawrie (1951) Theorell and de Duve (1947) crystallised myoglobin from urine in a case of myoglobinuria. We used the following methods, working at 0–4 C throughout:

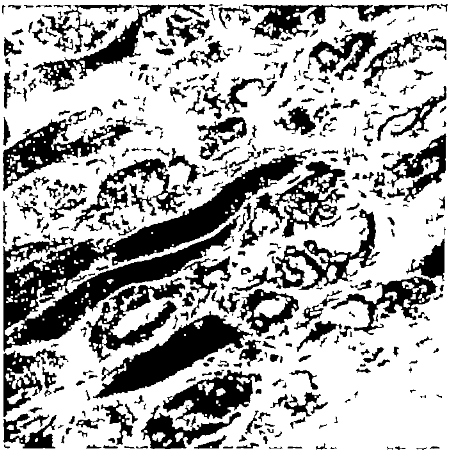

Fig 4—Muscle biopsy showing normal and degenerate fibres (Mallory's phosphotungstic acid hæmatoxylin ×186.)

(1) *After Rossi Fanelli (1949)*—Seitz filtered urine was dialysed against distilled water and then against numerous changes of 78% saturated ammonium sulphate at pH 6·8 It was next filtered and the brown filtrate was distributed in open petri dishes In a few days metmyoglobin crystals formed; most of them were spherical and very slightly birefringent with a tendency to split radially The spherical shape was probably due to impurities (R G Parrish personal communication) The rest were characteristically needle-shaped and birefringent sometimes several radiating from a common centre (fig 3)

(2) *After Rees (1949)*.—Seitz filtered urine was dialysed against distilled water next against 12% dextran to concentrate it, and finally against 3·5 *M* phosphate buffer of pH 6·4 The resulting dark brown syrupy liquid was left in an open test tube and gave again mostly spherical bodies together with a few cigar-shaped crystals

Histology—Four days after the onset of symptoms biopsy specimens of the left sacrospinalis muscle which was pale

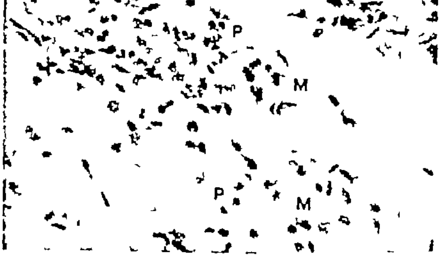

Fig 5—Muscle biopsy showing proliferation of sarcolemmal nuclei some of which are in mitosis (M); groups of polymorphs are present (P) (Hæmatoxylin and eosin. Glycol-wax embedding at 40 C. ×200)

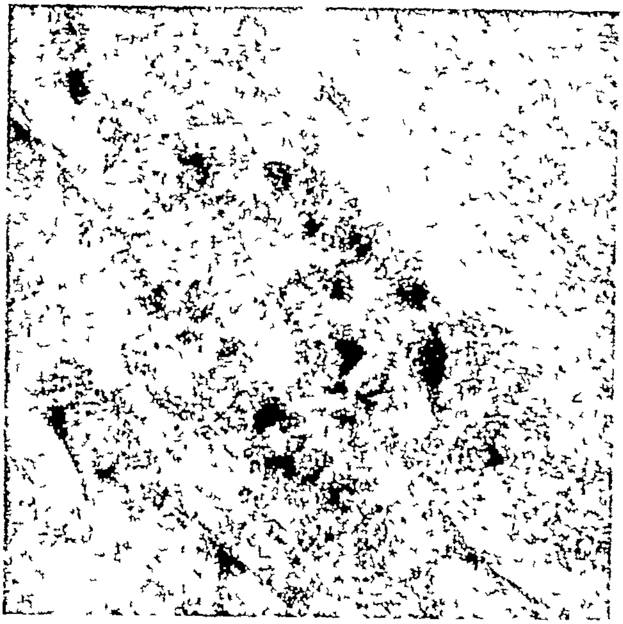

Fig 6—Muscle biopsy showing esterase in cytoplasm of sarcolemmal cells (Nachlas and Seligman's esterase method Formalin-fixed frozen section × 247)

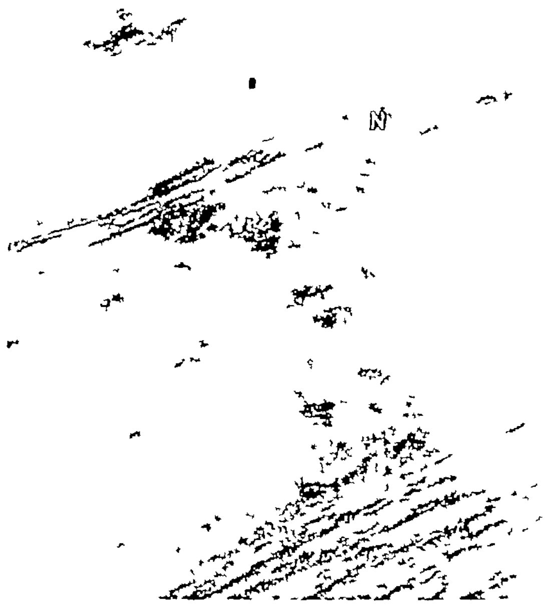

Fig 7—Muscle biopsy showing normal fibres (N), degenerate fibre intense granular birefringence (B), and optically inactive fi (Unstained paraffin section viewed between crossed polaroids. ×

soft, and swollen, and contracted poorly on stimulation, were fixed in formol saline solution, Helly's fluid, and alcohol, and paraffin-wax, glycol wax, and frozen sections were made Most of the tissue consisted of degenerate disrupted fibres with a few unaffected ones coursing among them The diseased fibres showed loss of striation, waxy degeneration, and fragmentation In a few places the muscle substance had contracted into a knot, leaving the sarcolemma empty and partly collapsed With Mallory's phosphotungstic acid hæmatoxylin, in contrast to the normal purple staining fibres, the degenerate fibres showed red brown complex coiled and branched figures in a pink matrix, while others showed pale blue homogeneous areas (fig 4) A few curled up strands still showed cross striation, more widely spaced than usual and without birefringence Stained with Masson's trichrome the degenerate areas were bright red, the empty sarcolemma blue and the normal fibres purple Abrupt transitions were seen in the same fibre from normality to severe disease There was multiplication of the nuclei of the sarcolemma, with many mitotic figures, many were surrounded by granular basophil cytoplasm The capillaries were crowded with polymorphs and some eosinophils, a few escaping into the surrounding tissue (fig 5) Some macrophages and normal numbers of mast cells were present There was no increase in collagen, and the reticulin frame work was normal The few vessels and nerve bundles seen appeared normal No motor end-plates were found in specially impregnated portions, a not unusual finding in a randomly selected biopsy (Woolf 1954)

Histochemistry—The histochemistry of normal muscle is reviewed by Dempsey et al (1946) and by Roskin (1952) In the present case there was complete loss of glycogen from diseased fibres and almost complete loss from normal fibres (Best's carmine stain) The weak beta metachromasia (Schmorl's thionin) of normal fibres in frozen section was absent from degenerate fibres, possibly owing to the loss of phosphorus compounds found in various myopathies (Nevin 1934) Staining with Fettrot 7B or with Sudan black B in propylene glycol, and with Nile blue, revealed no abnormality apart from absence of I band staining with Sudan black in fibres which had lost their striation Baker's acid hæmatin showed that the phosphatides were increased and uniformly distributed in the diseased fibres Similarly, acetone Sudan black (Berenbaum 1954) showed an increase in the bound lipids of these fibres These findings are of interest because the deposition of lipid in muscle is increased after denervation (Artom Friedlander et al 1941) and in vitamin E deficiency lis and Spencer 1936) No acid fast pigment, a charac feature of vitamin E deficiency in animals (Mason ford 1947) was present Small calcium deposits were seen in the most degenerate areas (cf Paul 1924) No ferric iron was found Azo-dye coupling methods (Pearse 1953) showed only traces of acid and alkaline phosphatases confined to vessels Dempsey et al (1946), who claimed to have found phosphatase in muscle fibres, exposed their sections to substrate for 24–72 hours, ample time for the production of artefacts, used Gomori's (1941) method, now well known to produce misleading pictures (Pearse 1953) Esterases were shown by the method of Nachlas and Seligman (1949) of incubating 37°C at pH 7 4 for 40 minutes, with alpha naphthyl acetate as the substrate Numerous esterase positive bodies were seen, evidently corresponding to the cytoplasm of proliferating sarcolemmal cells (fig 6) No myoneural junctions were seen Although some cholinesterase is associated with sarcolemmal nuclei and the sarcoplasm (Portugalov and Yakovlev 19 sarcolemmal cytoplasm is not normally stained by the technique Staining was unaffected by sodium taurocholate (5×10^{-3}M) Owing to unavoidable circumstances the effects of other differential enzyme-inhibitors were tested on tissues kept at –20°C for two days By this time any remaining enzyme activity was so low that the results were equivocal and the esterase could not be more precisely characterised Pickworth's benzidine stain showed patchy or complete loss of myoglobin from diseased fibres

Polarisation Microscopy—In paraffin sections the unaffected fibres were normally birefringent Here and there, an otherwise normal fibre showed an accumulation of granular intensely birefringent material along its edges The grossly abnormal fibres either consisted entirely of such material were optically inactive (fig 7) Insertion of a quartz first order purple plate (I wave length retardation) between, at 45° to, polariser and analyser gave a picture similar to that obtained by Matoltsy and his colleagues (Matoltsy Gerendás 1947, Gerendás and Matoltsy 1947, Gerendás et al 1947) during the extraction of actin and myosin from muscle and by Aloisi et al (1952) in rabbits with vitamin E deficiency In normal fibres the positively birefringent A bands were blue alternating with I bands of the same purple colour as the background In mildly affected fibres some of the I bands were negatively birefringent, varying from yellow to red, whereas the alternating A bands showed reduced birefringence More severely affected fibres showed progressive of striation, and replacement by yellow, orange, or granular and negatively birefringent material. The severely affected fibres were optically inactive Matoltsy his school consider that such changes are due to loss of positively birefringent actomyosin and the unmasking of negatively birefringent "N protein" Aloisi et al (19 however, think they are explained by loss of myosin depolymerisation and molecular rearrangement of actin.

Discussion

uscular Dystrophy

In 7 cases of paroxysmal myoglobinuria (not included the 15 listed above) muscular dystrophy was diagnosed inically or muscle atrophy supervened (Meyer Betz 911 Louw and Nielsen 1944 Scherwin 1945 Wissler 948, Kreutzer et al 1948, Acheson and McAlpine 1953 ipp and Shukers 1955) It has been suggested that aroxysmal myoglobinuria is simply an acute manifestaion of muscular dystrophy However muscle dystrophy as not supervened in some cases followed up for fifteen r sixteen years (communication of R Debré to Acheson and McAlpine 1953 and of R Hed to Elek and Anderson 1953) No muscle atrophy resulted from fifty attacks in seven years in the case published by Spaet et al (1954)

The specific histological features of muscular dystrophy are hypertrophy great variation in size and longitudinal splitting of muscle fibres, followed by fatty infiltration (Adams et al. 1953) In no case of paroxysmal myoglobinuria studied histologically were these features seen although muscular dystrophy cannot thereby be excluded

The appearance of myoglobinuria in muscular dystrophy is not surprising The renal threshold for myoglobin is 15–20 mg per ml of plasma (Yuile and Clarke 1941) only a fifth of that of hæmoglobin Myoglobinuria may therefore be caused by any sufficiently extensive and acute muscle damage A rough calculation shows that in an adult visible myoglobinuria may result from the destruction of about 200 g of muscle Myoglobin has consequently been found in the urine as a result of air raid injury (Bywaters and Beall 1941 Bywaters et al 1941) physical assault (de Langen 1946) electric shock (Fischer and Rossier 1947) gangrene due to arterial thrombosis (Bywaters and Stead 1945) and even it is claimed, severe exertion in healthy people (Ono 1953)

It may be presumed that in muscular dystrophy, muscle damage may progress sufficiently rapidly to cause myoglobinuria However this cannot be taken to mean that muscular dystrophy is the cause of every unexplained case of myoglobinuria where there is no supporting clinical or familial evidence

Carbohydrate Metabolism

Suggestions that paroxysmal myoglobinuria may be due to faulty metabolism of carbohydrate have been largely based on a supposed analogy to equine myoglobinuria (Carlström 1931) In Hed's (1947) cases attacks occurred on a low-carbohydrate diet, and glucose lerance curves were abnormal Abnormal curves and lycosuria have been noted in myotonic dystrophy Morgulis and Spencer 1930) but not in progressive uscular dystrophy (Tyler and Perkoff 1951) In the esent case renal glycosuria was the only relevant bnormality Disturbances of carbohydrate metabolism re possibly more the effect than the cause of the muscle isorder

ossibility of Abnormal Myoglobin

Several types of human hæmoglobin exist many of hich are a cause of disease (White and Beaven 1954) his fact suggests that an abnormal myoglobin may be cause of paroxysmal myoglobinuria The existence of fœtal type of myoglobin is suggested by the fact that yoglobins of fœtal and adult origins differ in extract bility from tissues (Björck 1949) in solubility (Jonxis nd Wadman 1952) and in light absorption (Rossi anelli et al 1951) A myoglobin relatively insoluble in he reduced state is suggested by the analogy of the bnormal hæmoglobin of sickle cell anæmia (Perutz and Mitchison 1950 Perutz et al 1951) Simple solubility elationships are unlikely to apply in the muscle cell argely occupied by organised protein structures and evere exertion or other factors may induce changes in oxygen tension pH &c., sufficient to render an abnormal myoglobin insoluble and incapable of carrying on its function of short term storage of oxygen (Millikan 1937 1939 Lawrie 1952) Theorell and de Duve (1947) found that the myoglobin in the urine in a case of paroxysmal myoglobinuria differed slightly from normal myoglobin in the shape of the crystals, light absorption and solubility Although these workers discounted these differences, we think they are at least suggestive and worthy of further investigation

The same considerations apply to the other proteins of muscle but knowledge of these is so rudimentary that even speculation about their rôle in this disease is unwarranted at present

The finding of increased red-cell fragility in the present case also found by Hed (1953) in 1 of his cases suggests that examination of all the hæm pigments in these patients might be rewarding

Summary

A case of paroxysmal myoglobinuria of unknown ætiology is described Myoglobin was found in the urine by spectroscopy and by crystallisation. For the detection of myoglobinuria we recommend conversion to carboxy compounds

Muscle biopsy showed severe degenerative changes the accumulation of an esterase in the sarcolemmal cells and the appearance of negative anisotropy during degeneration of fibres

The myoglobin content of the diseased muscle was much reduced.

14 previously published cases of myoglobinuria without another associated muscle disease are collected of which 5 were fatal. 7 additional cases were associated with muscular dystrophy

The ætiology is unknown We suggest that an abnormal myoglobin may be present

Many colleagues have helped in the study of this case Our thanks are due to Dr H Loewenthal senior pathologist Chase Farm Hospital, Dr R G Parrish, of the Royal Institution and Prof B K Johnson of the Imperial College of Science for much advice Prof W D Wright for permission to use the spectrophotometer Dr P Bauwens, of St Thomas's Hospital for electromyography and Mr R Smith, B.Sc Mr H Day and Mr E Siddle for technical help Mr H. Knight made the photographs Dr Leonard Crome and Dr H. Loewenthal translated several papers.

EVER since the introduction of cocaine as an anæsthetic agent (Koller 1884), attempts have been made to improve regional anæsthetics One that is long acting and has been introduced recently is 'Efocaine,' a solution of procaine (1%), procaine hydrochloride (0 25%), and butyl aminobenzoate (5%) in polythylene glycol mol wt 300 (2%), propylene glycol (78%), and water It has been recommended for intercostal and paravertebral block, for anorectal and peri-incisional infiltration, for musculoskeletal disorders, and for various minor operations Extensive use has been made of it and at first excellent results were reported (Iason and Shaftel 1952, Ansbro et al 1952, Deaton and Bradshaw 1953), although unpleasant after-effects were occasionally observed (Bonica 1952)

Since then, however, it has become increasingly evident that efocaine is far from satisfactory (*British Medical Journal* 1954), and several serious and occasionally fatal accidents have followed its use The case reported here illustrates these unfortunate sequelæ, although previous experience with the drug had been favourable

Case-report

An accountant, aged 64, was admitted on June 4, 1954

Eleven years previously, in 1943, he underwent a total laryngectomy for laryngeal neoplasm. He remained in good health until December, 1952, when he developed a carcinoma of anaplastic type in the region of the uvula Treatment was given with teleradium and he remained well for a further year until he developed a recurrence in the glands of the neck and in the pharyngeal region A further course of radiotherapy was begun with the patient attending as an outpatient Soon, however, he complained of pain in the interscapular region, radiating to the front of the chest and having the characteristics of root pain In spite of the usual analgesics this became so severe that he had to be admitted to hospital.

On admission his general condition was poor He spoke with an œsophageal voice and had an efficient tracheostomy An enlarged mobile gland 3 cm in diameter was present on the left side of the neck, and laryngoscopy showed an ulcerated carcinoma in the lower pharyngeal region The nervous and other systems were normal, apart from local tenderness in the upper thoracic region of the spine

Biopsy of the lymph gland showed infiltration by anaplastic squamous carcinoma Radiography of the thoracic spine showed no abnormality An electrocardiogram (E.C.G) was typical of posterior myocardial infarction

Operation for Relief of Pain

Under the influence of the radiotherapy the pharyngeal tumour and the enlarged gland underwent resolution, but the pain, which seemed to involve T2–T4 bilaterally, persisted, and large amounts of morphine were necessary to subdue it The patient was a very anxious and sensitive person and reacted excessively to his symptoms The relationship of the pain and the E C G findings was difficult to assess, and it was considered that despite the lack of radiological proof, spinal metastases with root involvement were probably the cause of the pain

To control this symptom a paravertebral block was suggested, and it was done on the left side first in order to assess the effect before doing it on the right On July 28 efocaine 3 ml was deposited around T3, T4, and T5 roots on the left. The operation was uneventful, but about ten mintues later the patient suddenly collapsed, with very low blood pressure, gasping and shallow respirations, and loss of consciousness. Intravenous nikethamide and a saline infusion were given and within two hours he had made an almost complete recovery , but damage to the spinal cord was now obvious

Spinal Cord Lesion

A partial Brown Séquard syndrome was present, with almost complete paralysis of the left leg and a sensory level at T3 The back pain was much less severe Treatment with an indwelling catheter, tidal drainage, and physiotherapy to the legs was begun at once An infection of the bladder responded to antibiotics, and three weeks later voluntary micturition was possible The control of bowel function which had also been affected, much improved Simultaneously the legs improved, and six weeks after the onset of symptoms the patient could walk a few steps with the aid of a walking machine The back pains had not returned, and he needed no analgesics

His progress, however gradually became slower, and about ten weeks after the paravertebral injections his condition began to deteriorate His legs became weaker , he could no longer stand or walk , and the sensory impairment was more obvious An enlarged lymph node was found in his neck. Sphincteric disturbances returned, and a bladder infection supervened Further radiographs of the thoracic spine were still normal Both motor and sensory paraplegia was now complete, and he died on Nov 27, 1954 six months after admission and four months after the paravertebral block.

Post mortem Findings

There were secondary deposits of carcinoma in lymph nodes of the neck, thyroid gland, and lungs Coronary occlusion with an old infarction of the posterior wall of the left ventricle, and bilateral bronchopneumonia were found together with bilateral pyelonephritis, acute cystitis and gangrene of the perineum

Transverse section of spinal cord and meninges at T3 showing meningeal reaction thickening of dura mater and neoplastic deposits in epidural fibrous tissue mostly on posterior surface.

In the epidural space at T2 T3 and T4 was a mass of brownish fibrous material covering mainly the left and posterior surfaces of the dural tube It was 1 cm. thick at T3 and compressed the spinal cord Microscopy of this region revealed disorganisation of the cord meningeal reaction, thickening of the dura mater and invasion of the epidural fibrous tissue by clumps of neoplastic cells (see figure) Tumour cells were present in the vertebral bodies of T1–T9 invading the posterior longitudinal ligament at T3

Comment

Despite the difficulties caused by the presence of two aetiological agents in this case the close relationship between the paravertebral injection and the lesion in the spinal cord is indisputable The thickening of the dura and some of the cord changes no doubt resulted from the injection The deterioration after a period of recovery was probably due to lymphatic spread of the malignant tissue in the epidural space; if this had not occurred considerable improvement in the spinal cord could have been expected In view of the persistently normal radiographs it is difficult to ascribe the initial back pain to involvement of the vertebræ Microscopy however showed that extension from the vertebral body of T3 into the epidural space had taken place

Discussion

Like many other workers we had previously found efocaine an efficient means of producing caudal block to control intractable pain resulting from inoperable carcinoma of the uterus or cervix Although leg weakness developed in 1 of 7 such patients extension of the disease was probably responsible for this

Previous Reports

We have now found 20 reports of spinal-cord damage produced by efocaine With our case the total is 21 but no doubt others have remained unpublished

Among the 14 recorded in detail there are 7 in which the efocaine was placed (often under direct vision) around intercostal nerves at the level of the transverse processes usually to combat postoperative pain (Shapiro and Norman 1953 case 1 Nowill et al 1953a, case 2 Brittingham et al 1954 cases 2 and 3 Berg 1954 Griffith 1954 Knight and Luth 1954) A paravertebral block was done in 6 (David 1953 Nowill et al 1953a; Brittingham et al. 1954 case 1 Hubbard 1954 our case) and the patient of Angerer et al (1953) had an intercostal nerve block

All the patients developed some degree of dysfunction of the spinal cord either immediately (as in our case) after some hours, or (as in case 2 of Brittingham et al 1954) after as long as two days An episode of acute shock such as occurred in our patient, has been reported only once (Angerer et al 1953) Details of the neurological findings are not always available but 4 patients had a complete and 7 an incomplete transverse lesion of the cord 5 of the latter had a type of Brown Séquard syndrome Death took place in 5 cases but in only 2 (Angerer et al 1953 David 1953) was it due directly to the efocaine in the 3 others (Brittingham et al 1954 Berg 1954 and our case) the primary condition for which efocaine had been used produced or contributed to the fatal outcome. Of the 9 known survivors 2 recovered well and were the only ones to walk again 4 improved slightly and 3 did not improve Those less severely affected were more likely to show recovery but the speed of onset of symptoms of the spinal lesion did not seem to influence the outcome

3 patients came to necropsy but in 2 cases (Brittingham et al 1954 case 1; Berg 1954) full details are not given In the patient who developed symptoms and signs of a spinal lesion after an intercostal nerve block in the posterior axillary line thrombosis of an intercostal vein and artery was found (Angerer et al 1953) There was widespread necrosis and acute inflammation of the spinal cord In our case the necropsy appearances were complicated by neoplastic invasion of the epidural space There is no doubt, however, that the epidural fibrous tissue and some of the disorganisation of the cord resulted from the paravertebral injection of efocaine

Method of Production of Damage by Efocaine

During a paravertebral injection the following possibilities of damaging the cord exist

(1) Introduction of the efocaine into the cord or subarachnoid space as has happened with alcohol (Molitch and Wilson 1931 Hirschboeck and Gillespie 1942 Mandl 1947) The presence of efocaine in the cerebrospinal fluid however does not necessarily indicate that this has taken place for Angerer et al (1953) found procaine in the cerebrospinal fluid although the efocaine was injected at least 8 cm. lateral to the spinal canal

(2) Injection of efocaine directly into the epidural space or near by so that it can readily find its way into it

(3) The case of Angerer et al. (1953) suggests that involvement of intercostal veins and arteries may occasionally cause damage to the cord

(4) Moore (1953) and Moore et al. (1954) have shown satisfactorily that efocaine injected into an intercostal nerve of a monkey can travel centrally by way of the perineural spaces of the nerves and roots to reach the parenchyma of the cord and damage it in some cases

It seems likely that any one or more of these mechanisms may take place and the second or the fourth probably is responsible for the present case

Effect of Efocaine on Nervous Tissue

Damage to peripheral nerves (Bonica 1952 David 1953) and other structures (Hubbard 1954 Knight and Luth 1954) has occurred in man and Margolis et al (1953) have produced it experimentally in various animals Mannheimer et al (1954) show that the effect of efocaine on a peripheral nerve is comparable to that produced by section The solvent vehicles in efocaine (propylene glycol and polythylene glycol mol wt 300) necrotise animal tissues (Maykut and Ryan 1953 Fabre et al 1953 Mannheimer et al 1954) and Nowill et al

(1953b) have confirmed this in man These substances are responsible for the long lasting anæsthetic effect of efocaine, but they produce their effect by destroying rather than anæsthetising tissues There can be little doubt that these suspending agents rather than the anæsthetics are the offending constituents of efocaine, and the benzyl alcohol in 'Symprocaine,' which has also damaged the cord (Panter 1953), probably plays the same rôle That efocaine is not always destructive is shown by our previous cases , but, in view of its deleterious effects in some people, it should not be brought into contact with peripheral nerves, roots, or spinal cord, and it would probably be wise to discontinue its use altogether

Summary and Conclusions

A case in which the spinal cord was damaged by paravertebral injection of 'Efocaine' is described, and 20 others are cited

In this preparation the anæsthetic agents are dissolved or suspended in vehicles capable of destroying tissues with which they are left in contact

Efocaine can damage nervous tissue severely, and when injected near the spine it may travel via nerves and spinal roots to the spinal cord to produce severe destruction

Its value as a regional anæsthetic is in question, and its use should probably be abandoned

Preliminary Communication

MAIZE AND PELLAGRA

MICROBIOLOGICAL and chemical evidence indicates that almost all the nicotinic acid in cereals, such as maize, wheat, barley, rye, and rice, is present in an alkali labile, " bound " form, that differs from the known nicotinoyl derivatives and is only partially utilised by *Lactobacillus arabinosus* and *Lb casei* [1] Hydrolysis with 0 5 N NaOH or strong mineral acids liberates the nicotinic acid which is then available to bacteria The " bound " form of nicotinic acid, present in maize and other cereals, does not appear to serve as a source of the vitamin for the nicotinic-acid-deficient rat [2,3] and chick [4,5] Experiments with pigs in which a deficiency of nicotinic acid had been produced on diets containing a large proportion of maize [6,7] indicate, by implication, that the " bound " form is equally unavailable to the pig There is no direct evidence about its availability or otherwise to man

The full biological activity of nicotinic acid for the rat can be released by hydrolysis with 0 5 N-NaOH,[2,3] but again the availability to man of such products is uncertain It was felt that experiments on the pig might help in answering this point, in view of the similarity of its nicotinic acid metabolism to that of man [9] The results are briefly reported here A full account of this work will be submitted for publication elsewhere

EXPERIMENTAL

Eighteen weanling pigs of both sexes, weighing 37–59 lb , from four litters were assigned to three groups In the preliminary stage of the experiment, a deficiency of nicotinic acid was induced in all groups by giving a maize diet similar to that of Chick et al ,[8,9] and consisting of ground white maize 79, pea meal 10 5, purified casein 5, cod-liver oil 3 salt mixture 2 5 When the pigs ceased gaining or lost weight they were put on the experiment proper group 1 (deficient controls) was maintained on the deficient diet, modified by replacing the maize with maize reconstituted from its milling fractions , group 2 (positive controls) received, in addition to this modified diet, 6 mg nicotinic acid daily , group 3 was given a diet in which the milling fractions of maize—namely, bran and hominy meal—containing most of the aleurone layer and 73% of the total nicotinic acid, had been hydrolysed for 30 minutes with 0 5 N NaOH to liberate " bound " nicotinic acid The pigs were maintained on these diets for 9 weeks or until they succumbed to deficiency They were weighed twice weekly and their daily food intake was recorded The free and " bound " forms of nicotinic acid present in the diets were determined microbiologically [10] and chromatographically [11] Tryptophan was estimated chemically [12]

RESULTS AND DISCUSSION

Preliminary Deficiency Period —Seventeen pigs became deficient within 17–63 days One animal, which had been assigned at the beginning of the experiment to group 3, did not become deficient during the period of the experiment and was therefore not included It became deficient only in the 14th week and was killed in a moribund condition for post-mortem examination

Experiment Proper —The seventeen deficient pigs in the three groups were given, over a period of 9 weeks their experimental diets The average weight gains of the three groups are shown in the accompanying figure The average weight of the deficient pigs (group 1) did not increase , two animals finished the experiment in a moribund state and two others died in the 4th and 5th weeks The remaining two pigs completed the experiment without showing signs of deficiency Both required an exceptionally long preliminary period, 59 and 63 days before they ceased to grow One of them resumed growth shortly thereafter , the other at first lost weight but recovered towards the end of the experiment Such a recovery has been observed by other workers [6,7] All the pigs supplemented with 6 mg nicotinic acid daily (group 2) recovered from the deficiency and maintained a steady gain in weight The pigs given the alkali hydrolysed maize fraction (group 3) recovered also and gained in weight, though at a slower rate than the animals of group 2 which received the nicotinic acid supplement

Average weight-gain of pigs deficient in nicotinic acid receiving various treatments.

1 Group 1 deficient controls.
2 Group 2, positive controls, receiving 6 mg nicotinic acid daily
3 Group 3 receiving alkali-treated maize fraction.
(+) Death of animal

The average weight gains intake of food of nicotinic acid and of tryptophan are given in the table It will be seen that the control pigs lost some weight that the other two groups gained appreciably and that they also ate much more food and that these differences were statistically significant

Pigs of group 2 that received nicotinic acid grew significantly better than those of group 3 on hydrolysed maize they also ate more but this difference was not statistically significant. The deficient group 1 consumed on the average 7 7 mg daily of nicotinic acid of which only 0·8 mg was considered to be available The vitamin supplemented group 2 had 20 8 mg total nicotinic acid daily of which 7 6 mg was available Group 3 on the diet in which 73% of the nicotinic acid present in maize had been liberated by alkaline hydrolysis, had daily 9 6 mg nicotinic acid in free form out of a total of 12 6 mg It thus appears that the recovery of the pigs in group 3 was correlated with the availability of nicotinic acid as found previously in rats [illegible] The curative action of the hydrolysed maize diet given to group 3 was in striking contrast to the pellagra producing action of the untreated maize diet given to the same pigs in the preliminary deficiency period when they consumed about the same amount (10·8 mg) of nicotinic acid but almost all in 'bound form We conclude therefore, that the main factor responsible for the recovery of the pigs in group 3 was the availability of free nicotinic acid We cannot however exclude as a contributory factor some other changes in the bran and hominy meal fractions which may have occurred during the relatively mild alkaline hydrolysis That there may have been some alteration in other constituents—e.g in the proportion of amino acids [13]—is indicated by the fact that the pigs of group 3 though they consumed more free nicotinic acid than the vitamin supplemented group 2 did not do as well as the latter

EFFECT OF ALKALINE HYDROLYSIS OF MAIZE FRACTIONS (BRAN AND HOMINY MEAL) ON THE AVAILABILITY OF NICOTINIC ACID FROM MAIZE TO DEFICIENT PIGS

(Average weight gain intake of food nicotinic acid and tryptophan calculated for a period of 9 weeks)

Group	Diet	No of pigs	Weight gain (lb per week)	Food intake (lb per week)	Intake of nicotinic acid (mg per day)		Intake of tryptophan (g per day)
					Free	Bound	
1	Deficient	6	−0 2 ± 1 26	1 3 ± 0 32	0 8	6 9	0 8
2	+ nicotinic acid 6 mg per day	6	5·0 ± 0 33	[illegible] 5 ± 0 15	7 6	13	1 5
3	Hydrolysed maize fraction	5	3 [illegible] ± 0 02	2 1 ± 0 17	9 6	3·0	1 3

Standard error

As pigs react to a deficiency of nicotinic acid in many ways similarly to man, it is possible that the following considerations apply to both species

(1) If the 'bound" nicotinic acid is not available to man, the only factor that determines the pellagra preventive potency of a cereal would be its tryptophan content, and *possibly its ability to alter by its own* amino acid content the imbalance of amino acids in the diet [13] Thus there is in these circumstances no need to postulate a toxic factor in maize to explain its pellagra producing properties

(2) The daily requirement of man has been estimated, on the basis of the average intake in the diet to be 12 mg nicotinic acid [14] In this value is included the ' bound ' *nicotinic acid in cereals that may amount to about* 30–50% of the total nicotinic acid intake from an ordinary diet If the bound nicotinic acid is not available the above estimate of the daily requirement will be too high and should be reduced An amount of 6–8 mg daily seems a more appropriate estimate This value agrees well with the curative doses of yeast which were needed by Goldberger and Tanner [15] to cure pellagrins.

(3) Alkaline treatment which liberates the ' bound nicotinic acid in cereals could be a possible way of enrichment of the foodstuff In this connection treatment of maize with lime water has been reported to cure nicotinic acid deficiency in rats [16 17] and it has been suggested that lime water treatment of maize as practised in Mexico may be responsible for the low incidence of pellagra among maize-eaters in that country However this mitigating effect of treatment with lime water has not been observed in other laboratories for both the rat [18] and man [19] The explanation of these discrepancies has to await further experiments.

Dame Harriette Chick and the late Sir Charles Martin took a keen interest in this work and we derived much benefit from talks and discussions with them. The experiments would not have been possible without the generous assistance we received from Quaker Oats Ltd Southall, Middlesex who carried out the large scale hydrolysis and preparation of the maize fractions We are particularly grateful to Mr B C L. Summers and Mr J J Holt of that company for their willing help We wish also to thank Mr P Wilson for technical assistance

Medical Societies

ROYAL SOCIETY OF MEDICINE

Intraventricular Administration of Drugs

ON April 19 the section of psychiatry, with Dr W MAYER-GROSS, the president, in the chair, had the opportunity of hearing, from colleagues in other disciplines, about some recent work on the injection of drugs into the ventricular system of the brain

IN THE CAT

Dr W S FELDBERG, F R S, described, as a physiologist, the method he and Dr S L SHERWOOD use with cats, and showed a film illustrating some of their results Drugs injected into the lateral ventricles, he said, come into contact with the important masses of grey matter lying round the third ventricle and the aqueduct

In this study the injections were made into the ventricles of conscious cats The method first used was to bore a hole through the cat's skull, under general anæsthesia, and allow the skin to heal over it, injections could then be made through the skin But the method was frightening, the cats struggled, and had to be restrained, and the person making the injection had no confidence that he was in the lateral ventricle rather than the surrounding brain tissue Moreover, the cats soon became hostile A 'Polythene' covered cannula has therefore been devised which can be implanted at operation, screwed into the skull and left in position It is closed at the top by a rubber diaphragm, and injections can be made through this without annoying the cat—which is held gently in position by an assistant

The film showed the operation for implanting the cannula in an anæsthetised cat, the normal behaviour of the recovered animal, and radiographs of the skull with the cannula in position Cats tolerate the cannulas well, and some have had them implanted for over a year

The effects of various drugs were also shown After *acetylcholine* the cat retched, gave a few cries, and then sat still and subdued until the effects wore off After *atropine* the same cat became lively, and appeared to be enjoying itself, rolling on its back or pacing and prancing Its appraisal of its surroundings, however, seemed to be impaired, for it ignored a hand stretched out to it—though before the injection it had played readily with the assistant's hand, reaching up to it with its paws and head With larger doses of atropine it retched and vomited, its breathing became rapid, and its nictitating membranes relaxed and spread partly across the eyes

Under *adrenaline* or *noradrenaline* the cat became completely relaxed, drowsy, and flabby—laid out, as though under pentobarbitone ('Nembutal') With methantheline ('Banthine') there was also retching, vomiting, and rapid respiration The cat used in this experiment was unable to stand or walk and developed nystagmus while under the influence of the drug, even though this was given in doses which would have had no effect if given intravenously *Tubocurarine* produced salivation, defæcation, much plaintive crying, and finally convulsions—which were checked by giving intraperitoneal pentobarbitone This cat, in spite of its experiences, was very friendly on recovery from the drug, and appeared to have forgotten the whole episode—in contrast to the cats in the original experiments, which long remembered resentfully attempts at injection

A very lively cat was chosen for injection with the *anticholinesterase* drug, di isopropylfluorophosphonate (D F P) After the injection it at once began licking and scratching itself as though afflicted with violent irritation over its body and head, but the delayed effect of the drug was to put the cat into catatonic stupor during which it would retain for as long as ten minutes any posture into which it was put It was perfectly capable of normal movement, however, for when it had remained for some time balanced across the stretchers of an upturned stool, a gentle push from behind caused it to jump down in its usual well coördinated manner

Dr Feldberg believes that these are central effects, not due to any considerable absorption of the drugs into the [illegible] circulation for atropine, when injected intra[illegible]y, has no effect on the pupillary reflex, and tubocurarine produces convulsions instead of the paralysis seen when it is given subcutaneously Retching and vomiting followed the injection of many drugs, no doubt because they are all injected into the same region, but otherwise the variety of symptoms produced is considerable, including drowsiness, convulsions, catatonia impaired awareness, sleep, muscular incoordination, and spastic paralysis The scratching and licking after D.F.P is also a central, not a peripheral, effect, for the same behaviour can be produced by electrical stimulation of the midbrain The pruritus produced by morphine may be of similar origin, and so may the itching of lichen planus, which is relieved dramatically by the removal of a few millilitres of cerebrospinal fluid (C S F) at lumbar puncture D F P produces catatonia resembling that seen in schizophrenia This drug has been tried in the treatment of patients with myasthenia gravis, but has been given up because they complained of insomnia and terrifying nightmares and hallucinations Given to schizophrenics, it was found to exacerbate the psychosis Accumulation of acetylcholine in the midbrain may perhaps be responsible for clinical catatonia Some of the drug actions studied may be an imitation of actions occurring normally in the brain tissue round the third and fourth ventricles

Dr S L SHERWOOD had begun intraventricular experiments after exploring the electrophysiological aspects of this work in W S McCulloch's laboratory in the Illinois Neuropsychiatric-Institute, and he is now working with Dr Feldberg He has studied the response to various drugs in 26 psychotic patients of long standing Their ages ranged from 20 to 47 and their psychosis had persisted for periods of three to twenty three years, and 20 of them were schizophrenic, 7 had been leucotomised before the drug injections were started, 7 had leucotomy after the study had begun, and 8 had no surgical treatment In each case the cannula was introduced into the lateral ventricle by the same technique as that used in the cats, and electroencephalographic and other observations were made on the effects of different drugs

Adrenaline was tried in 5 patients, 4 of them with catatonia and 1 with epilepsy, the drug produced general relaxation and lowering of muscle tone, the rigid patients letting their heads sink back on the pillow There was no paralysis In 3 patients there were flushing, sweating, nausea, and vomiting and all became drowsy within ten to thirty minutes, though they were easily roused Those who had been inaccessible responded to simple questions, and one who had not spoken for years remarked "I wish someone would do this to you, doctor" The effects wore off two to three hours later, leaving them as they had been before the injection except for some slight increase in spontaneity

The results of *atropine* (3 cases) were inconclusive, but spontaneous movements of a relaxed kind increased, and the patients showed a readiness—quite unusual—to smile and giggle Methantheline was given to 11 patients (9 cases of catatonia, 1 of paranoid, and 1 of simple schizophrenia), an hour later they were all more active than they had been Given large doses they became overactive, and showed signs of distress so that the drug had to be stopped They described hallucinations and delusions, and while some of them were aware of the abnormality of these experiences, they did not lose them Under the influence of the drug, Dr Sherwood noted their complexions improved *Cholinesterase* was tried in 15 cases, but it was difficult to get enough of the drug in a pure condition most early preparations caused nausea and vomiting and a fall of blood pressure The best source proved to be a soluble preparation from human red cells, and preparations made from this were less toxic Within a few minutes of the injection the patients flushed and became more accessible and after two to three hours they had improved sufficiently to look after their personal needs in 6, indeed behaviour approached normal In one this improvement has persisted for four years and in another for two, both had been leucotomised before receiving this treatment All patients became more alert and coöperative, but 2 became agitated—perhaps because of increased awareness

On the effects of *hyaluronidase* both alone and with other drugs, no definite conclusions were reached.

Serotonin was given to 4 patients. Within a few minutes they began to yawn and clear their throats they flushed and then paled and sometimes vomited They began to talk freely—one sang and shouted—though there seemed to be no change in their thought processes Still they were more pliable more interested and cleaner One was able to go home for three months.

Some of the responses seen—such as vomiting, a fall of blood pressure and of C.S F pressure, and improvement of complexion—were common to many drugs Some women with amenorrhœa began to menstruate again He emphasised the suitability of intraventricular injection as a tool for the study of mental illness

Dr DEREK RICHTER commented on the value of interdisciplinary collaboration it cannot be often that a neurosurgeon and a physiologist have worked together He was impressed by the extent of the field opening for research and looked forward to still wider collaboration Perhaps a competent psychologist could add to the value of experiments such as this by assessing animal behaviour—for instance by the use of animals trained in mazes In cats licking and washing is perhaps a frustration symptom it is hard to understand it It would be interesting to study the effects of the hallucinogens by this method In the past decade we have recognised that the different brain centres differ in biochemistry and this method should add to our knowledge of their metabolism

Mr R H J WATSON described some results of feeding anticholinesterase to rats in order to reduce their cholinesterase level He has measured their behaviour in terms of their capacity before and after to solve problems and he has noted that it is more difficult to extinguish conditioned responses in them after feeding than before He compared this with the greater difficulty of extinguishing such responses in introverted, as compared with extraverted people In the deeply introverted schizophrenic extraverting drugs such as cholinesterase might be expected to produce improvement

The CHAIRMAN asked why, when the circumventricular brain substance already contains more adrenaline than other parts of the brain, the injection of adrenaline should have a sedating effect Dr FELDBERG replied that a substance like adrenaline which occurs naturally in the body presumably needs to be released into a form in which it can act he cited the case of the action of acetylcholine in a sympathetic ganglion

New Inventions

A LABOUR-WARD BED FOR SAFER ANÆSTHESIA

THE dangers associated with the inhalation of stomach contents during anæsthesia in obstetric practice have recently received considerable attention and there are many factors which make obstetrical anæsthesia specially hazardous In one respect patients who are anæsthetised on a labour ward bed are at a special disadvantage because there is not usually any mechanism for rapidly lowering the head Some obstetric beds do have a tilting-device, but at best it is of a type that involves delay in operation and during this delay vomit may be inhaled The proper management of regurgitation of stomach contents under anæsthesia is to recognise it immediately and immediately to lower the head so that postural treatment has been adopted before the vomit can be inhaled Immediate recognition is a matter for the vigilance of the anæsthetist but it is no less essential that the mechanical device for changing the patient s posture shall operate at a moment s notice

The ordinary obstetric bed in use at Guy s Hospital is simply a wide bed with a solid top and fitted with staples on one side to receive lithotomy poles when the patient is anæsthetised in the cross bed position The tilting device here described has been adapted to this bed.

In the new bed the upper surface is divided into three equal sections. One side of the middle section pivots between the adjacent top and bottom sections, while the other side of the middle section is free to fall below the level of the other two sections thus giving the patient s whole trunk a head-down inclination when she is in the lithotomy position across the bed The normal horizontal position of the middle section is maintained by an extra leg which pivots freely on the side-bar of the middle section If it becomes necessary to tilt the patient a sharp kick on the pivoted leg sends it under the bed and the middle section immediately drops into a tilted position

The chief problem in design was to devise a pivoted leg which was rigid enough to prevent the unintentional collapse of the middle section yet free enough to yield instantly to an intentional but moderate push with the foot. Mr W P Bentley chief engineer Guy s Hospital solved the problem by suggesting a leg mounted on a wheel to which a foot brake is attached With the brake on there is sufficient friction between the rubber tyre of the wheel and the floor to prevent the leg from slipping in response to accidental pressure On the other hand a deliberate push on the foot-brake first releases the brake and then continues easily to displace the leg on its free-running wheel thus the middle section collapses immediately Two springs under the middle section help to cushion the sudden fall And bolts are provided to lock the middle section securely when the bed is in routine use with the unanæsthetised patient The mattress is, of course divided

This bed has been made by Mr F Woodall, of Guy s Hospital works department, and his ingenuity and craftsmanship have overcome many difficulties of detailed construction These constructional details will differ with different types of bed to which the principle may be applied It is my purpose now merely to draw attention to the principle of the device for immediately lowering the patient s head by a simple movement of the foot so that precious seconds are not wasted after the patient has vomited and so that the hands of the anæsthetist may be free for other urgent duties

Reviews of Books

Fundamentals of Radiobiology

Z M BACQ, professor in the University of Liège, PETER ALEXANDER, Chester Beatty Research Institute, Institute of Cancer Research, London London Butterworths Scientific Publications New York Academic Press 1955 Pp 389 40*s*

RADIOBIOLOGY is concerned with the study of radiation effects on living matter It is a fairly new branch of science which has become very important since the release of nuclear energy Professor Bacq and Mr Alexander have written a fascinating and valuable survey based on the results of extensive research, scattered through 960 publications Besides presenting the physical and chemical aspects of radiation in an easy and understandable manner, the book offers useful information, not only to those engaged in fundamental research on radiobiological problems, but also to those using radiation with a practical aim

The chapter dealing with the pathological effects of radiation on biochemical functions is of special interest The authors draw attention to the fact that, except during the last days of life, little change is caused by sublethal doses of irradiation on general metabolism. The book summarises a great amount of experimental work on the processes by which normal physiological conditions can be re established after irradiation The practical aim of such investigations is to provide a scientific basis for the treatment of radiation victims

The difficulties met in the interpretation of complex reactions—e g, the rôle of adrenal hyperactivity and of the pituitary in radiation sickness—are indicated Clinicians in general, and radiotherapists in particular, will be interested in the section on chemical protection against X and γ radiation, which includes a discussion of the possible biochemical mechanism by which various substances protect from radiation injury There is a chapter about protection by shielding part of the body and by the injection of spleen and bone marrow homogenates The last chapter surveys the pathological effects of atomic explosions and gives a brief account of the genetical hazards of radioactivity

The book is well documented and illustrated and is written in a lively style Professor Bacq and Mr Alexander have made every effort to represent the selected material objectively, and their book will appeal to all who are working with radiation and are interested in radiobiological problems

Amphetamine in Clinical Medicine

Actions and Uses W R BETT, M R C S, F.R.S.L, LEONARD H. HOWELLS, B SC, M D, F.R C.P, physician, United Cardiff Hospitals, A D MACDONALD, M A, M D, M SC, Leech professor of materia medica, therapeutics, and pharmacology, University of Manchester Edinburgh and London E & S Livingstone. 1955 Pp 78 7*s* 6*d*

THIS well-produced little book "is intended merely as a guide to the general practitioner as to when and when not to employ this basically useful drug" The chapter headings show that amphetamine is most widely employed in borderline conditions between the physical and the psychiatric. Psychiatrists may feel that in such conditions as fatigue and depression, psychopathic states, and enuresis and behaviour disorders in children the psychological approach is more fruitful than the pharmacological Experience of alcoholism and other drug addictions, the subject of another chapter, shows that amphetamine may play a major rôle in maintaining such addictions The book is useful as a record of the conditions in which amphetamine has afforded opportunity for attempts at symptomatic treatment

Maladies de l'intestin et du péritoine

JEAN RACHET, ANDRÉ BUSSON, CHARLES DEBRAY Paris Flammarion 1954 Pp 1104 Fr 9400

THIS loose-leaf book is one of the series of modern French textbooks edited by Prof Pasteur Vallery-Radot and Prof Jean Hamburger The intention is to keep this [illegible] up to date by issuing yearly supplements and revisions In this volume Dr Rachet and his colleagues give a full account of diseases of the intestine, rectum, and peritoneum

In the first chapters major symptoms are discussed generally Detailed descriptions of individual diseases follow, with numerous references and illustrations Some of the latter are excellent, and indeed the whole production is extremely good To the English reader it may seem that undue emphasis is given to such matters as the size and position of the colon, since many physicians in this country attach little importance to ptosis of the colon or whether it is long or short On the other hand the account of intestinal gas is particularly good and not easily found in English textbooks The sprue conditions receive no more than 20 pages and the effects of wheat gluten in the diet in cœliac disease and steatorrhœa is only mentioned briefly

A number of uncommon diseases are included, but a few rare conditions such as Whipple's disease seem to have escaped notice The index is perhaps hardly as full as might be wished, but the orderly arrangement of the subject matter makes this a good book of reference

The Path Through Penguin City

HARRY R LILLIE, B SC, A M I C E, M B London Ernest Benn 1955 Pp 302 25*s*

As an engineer, biologist, and doctor, Dr Lillie covers a wide range of subjects in this book, but if his *Path Through Penguin City* is labyrinthic there is a guiding thread in his exhortation "Don't let us hate, but seek to help, that we may co-operate in brotherhood with all the creatures of the earth"

The book includes a full account of his commendable efforts towards promoting humane killing methods in whaling, interesting observations on the wild life of the Antarctic, reflections on the basic values of life, and a naturalist's excursions into theology In fable like conversations with him the penguins, gallant ambassadors of the whales, arraign man as the breaker of the peace of their realm He ends with a vision of Nature taking her revenge for the misdeeds wrought by man against his fellow creatures. Dr Lillie's colleagues may be disappointed that he has not told them more about his medical work in the Antarctic The drawings and photographs are from Dr Lillie's own pen and camera

---

My Fight against Osteo-Arthritis (*London* Faber & Faber 1955 Pp 105 8*s* 6*d*)—This little Pilgrim's Progress describes how Eve Orme, attacked early by osteo arthritis of the hip, has come by painful stages to recognise and sum up her enemy, to face him squarely, and, with professional help, to parry or soften many of his blows For fellow patients the story and her reflections and practical advice should be most helpful Her medical advisers come out of the tale better than other healers Her best friend, found through a clinic, was a skilful and imaginative physiotherapist A wise, candid, tolerant, and friendly little book

Physical and Psychical Research (Reigate Omega *Press* 1954 *Pp* 213 15*s*)—Psychical research seems to have a fascination for some physicists, as famous names attest. Isaac Newton was the greatest of these parergal inquirers into "the more far flung regions of human experience and thought"—as Mr C C L Gregory and Miss Anita Kohsen, the authors of this book, call their paranormal field—but he was not the most fortunate in his choice of subject and method Mr Gregory and Miss Kohsen approach psychology, psycho analysis, and parapsychology with a sophisticated understanding of the modes of thought that prevail in the natural sciences and are usually considered essential for any scientific work They hold that we may be satisfied with knowledge derived by either logico deductive synthesis, inductive synthesis, operationalism, or intuition, subjects of inquiry such as dynamic psychopathology and psychical research which do not derive support from the second or third of these functions are in a weak position at present After covering a wide field in their review of the nature of belief and acceptable evidence, they plead for less scepticism and a loosening of the conceptual requirements of science, which should not, in their view, be necessarily self validating Though their argument is suggestive, they do not sufficiently consider the routes of error, so easily trodden when the traveller leaves the sanctioned highway

THE LANCET

LONDON SATURDAY APRIL 30 1955

Surgery of Temporal-lobe Epilepsy

HUGHLINGS JACKSON over seventy years ago suggested that certain epileptic phenomena in which the aura or the whole attack consisted in a dreamy state—often with semi purposive automatic movements, or ill-defined *hallucinations of smell or taste* or of epigastric sensation—reflect a discharging lesion in the temporal lobe. During the past decade this concept of "temporal lobe epilepsy" has been elaborated, largely with the help of more accurate electro-encephalographic techniques for localising the site of electrical discharge. The group of epilepsies so defined is often associated with personality disorders which may be grave, indeed it is becoming more and more likely that these are the cases that have given rise to the idea of the epileptic personality and epileptic deterioration. Furthermore as the number and range of anticonvulsant drugs has increased it has become clear that they are especially resistant to drug treatment, and sometimes when control of the fits is achieved, the personality disorder grows worse rather than better. The possibility of successful surgical treatment is therefore particularly worth exploring.

PENFIELD and FLANIGIN[1] in 1950 reported the results of excising the anterior part of one temporal lobe in which a recognisable macroscopic lesion was held to be causing fits: abolition or great reduction of attacks followed in over half of their 55 cases. BAILEY et al[2] in 1953 recorded considerable improvement both in fits and in associated psychiatric disorders in 42% of 64 patients, in many of whom the diagnosis was less definite in that no macroscopic lesion had been demonstrated though the general clinical picture and pattern of attacks and a localised electrical abnormality were regarded as sufficient indications for excision. In our last issue Mr MURRAY FALCONER and his colleagues summarised further encouraging results. Of 30 patients 27 had complete or considerable relief from fits, and of the 29 who had an associated personality disorder 20 showed improvement in this also. These workers emphasise that, as PENFIELD suggested, removal of the deeper structures of the lobe—the uncus, hippocampus, and amygdaloid complex—is desirable. They also make a small but important technical advance in endeavouring to remove the lobe in one piece, which offers far greater opportunity for histological study.

Both from these observations and from the number of cases now being treated surgically it is clear that the operation holds promise. Nevertheless very careful thought is needed before recommending any procedure that involves irreversible change to the brain, and we must know as certainly as possible what psychological changes it is likely to induce. After his temporal lobectomy on the dominant side FALCONER notes a slight nominal dysphasia in a third of his cases, and some impairment of verbal learning. How far these will be a disability must depend on the nature of the patient's life and work. Perhaps more important ultimately, however, are the finer personality changes that might follow—changes less likely to emerge in formal tests than to be seen by those living in intimate contact with the patient. At this stage we should take with a gram of salt any dogmatic statement that no such alterations occur, bearing in mind the earlier experiences with leucotomy, and the evident association between disorder of personality and lesions of the temporal lobe. We must also be certain that improvement is specifically due to removal of temporal lobe tissue which is behaving abnormally. There is a growing tendency to bare cortical excisions for epilepsy mainly on the site of localised electrical abnormality, but such abnormality may be transient nor need it necessarily be initiated at its site of cortical manifestation (GIBBS,[3] RUSSELL MEYERS[4]). Even at the morphological level, the causative association between the lesion and the epilepsy can be criticised, as is done by Dr CROME on p. 882. Such arguments cannot invalidate good clinical results of surgical treatment but they reinforce the demand for adequate clinical assessment over an adequate period. BAILEY et al[2] conclude their paper by saying that "no appraisal of the surgical treatment of epilepsy will have much validity unless at least five years have elapsed since operation in every case", and most people who are experienced in the management of epilepsy will welcome these cautious words.

The decision to operate will always have to be made on an individual judgment. In some cases the chance of even temporary improvement, especially where there is a serious personality disorder, will outweigh other considerations. But as it is at present unlikely that in this difficult field of treatment operation will be lightly withheld, the need is chiefly to temper enthusiasm. Those now engaged in this work are evidently well aware of the still unanswered questions it poses. Such teams as those of FALCONER and his colleagues from the Guy's Maudsley unit are particularly well qualified to answer them, and in doing so they will not only advance therapy but add to our knowledge of cerebral function.

Medical Education

OUR students get a vocational training in clinical medicine, preceded by a period of preparatory education in relevant basic sciences. The vocational training has become unsatisfactory because the student is confronted with more and more information and techniques which distract his attention from essentials; and the educational preparation has become unsatisfactory because from the earliest stage the student is taught a great deal that he has no need or wish to know. The earlier part of the curriculum ought to be more vocational[5] and the later part more educational: we should recognise that the attempt to be comprehensive is futile if it prevents comprehension; and we should urgently be seeking, for our students, a new balance between principles and practice which will make them better qualified to practise medicine as it is and will be Yet in Britain we have hardly made any progress towards doing these things

In the basic sciences which we teach, many changes have taken place[5], and these are well described by Dr D C SINCLAIR, demonstrator in human anatomy at Oxford, in a book on *Medical Students and Medical Sciences* [6] which could be read with advantage by clinical as well as preclinical teachers As they have grown, the basic subjects have been affected by what SIR RUSSELL BRAIN has called the " counter current of specialisation " and have become more intimately mixed with each other Anatomy, aided by radiology, is able to leave the cadaver and begin the study of living structure Physiology, which gave birth to biochemistry has now (as SINCLAIR points out) a child as big as itself, and it has also spread so far and wide that there is some doubt as to exactly what remains at the centre Moreover, though anatomy, physiology, and biochemistry are still the mainstay of the preclinical curriculum, biophysics and statistics are now with good reason beginning to be admitted Most people recognise, too, the need for future doctors to learn something of the development of the human mind and of its normal reactions, though this does not necessarily imply recognition of psychology as a science (SINCLAIR, as an anatomist suggests that medical students would perhaps learn all the psychology they need by watching general practitioners at work to which some psychologists and possibly many general practitioners might retort that the same process would teach the student all he is likely to remember of anatomy) As for morbid anatomy, which has so long (in Britain) been neither preclinical nor clinical, but a curriculum in itself, increasing knowledge of function and dysfunction shows that it can no longer be expected to provide all the answers The necropsy-room is still a palace of truth, but the truth it offers is not the whole truth

SINCLAIR has lately made a study of medical schools both in this country and in the United States, and all who have done likewise will agree with him that we have been relatively slow to translate the above changes into teaching practice Efforts have been made, especially in anatomy and physiology but, as he says, " there are still many schools where the formal lecture course deals in full textbook detail with the scientific side of Pathology, where the museum of gross specimens is the main feature of the teaching, where there is little liaison between clinicians and pathologists, and where the emphasis is on making the students into pathologists rather than on making them into doctors " (Indeed in some schools there is little liaison even between bacteriologists and morbid anatomists) In the United States there is at least much awareness that times have changed and that new problems of education cannot necessarily be solved by old methods Furthermore, American universities, themselves primarily responsible for maintaining the standard of their graduates, are free from external restrictions on their curricula and thus have the great advantage of freedom to experiment Many have made use of advantage, and in terms of changes in the preclinical curriculum, which in America includes pathology, two main aims are discernible

The first is to increase the integration of the basic sciences with each other, grouping them in time so that the student passes from study of normal structure and function to that of abnormal (In Western Reserve University the experiment of integrating the preclinical subjects with clinical work is in progress) Though the value of these experiments cannot yet be gauged, there is at any rate no doubt that any medical school in which the staff get together to plan a new and improved programme benefits greatly from the resultant integration of the teachers, irrespective of any changes that may or may not be made in the curriculum.

The second aim has been to correlate preclinical studies more closely with clinical work In many schools this goes well beyond the liaison between the departments of physiology and medicine which is customary in Britain and in some it seems indeed, to go beyond the limits set by the maturity of students in their first and senior years and by their lack of any clinical technical skill We should do well to study these schemes and note their practical difficulties, for they are attractive in principle and frequently advocated It should be remembered however, that one of the reasons for bringing clinical work into the preclinical period is to attract the student—to offer a clinical carrot to a preclinical donkey—and it seems preferable in principle to make basic sciences interesting and exciting in their own right, as they certainly can be It is also relevant that the student is increasingly confronted with science during the clinical part of his training, and now finds that he learns much physiology from the cardiologist and the neurologist just as he has always learnt surgical anatomy and surgical pathology from surgeons This natural evolution has been recognised in some schools in America, and at Johns Hopkins (the traditional home of basic sciences) only an introduction to physiology is given in the preclinical department, the remainder coming later from the staffs of the medical and surgical departments of physiology

Reorganisation of the curriculum is not a cure for all ills, and tinkering with it does more harm than good Yet in SINCLAIR's words, ' unless we are constantly thinking over how the form of our teaching could be made more stimulating and thus more valuable, it is fatally easy to slip into the comfortable bonds of routine, and to be satisfied that if the student complies with the statutory regulations of the medical degree we have done our best by him "

In the final analysis the most important factor in medical education will always be the attitude of mind of the teacher Since the late war there has been a shortage of preclinical teachers, and it is to be hoped that SINCLAIR is right in thinking that today " academic work in Britain is no longer quite the bad financial proposition relative to clinical work that it used to be, bearing in mind the many advantages of the quiet life " But unhappily the possession of the strongest team of basic scientists gives no guarantee of keen and able teachers " The Great Teacher," SINCLAIR aptly remarks, has been replaced by " The Great Research Worker ' and for many teaching is a " tedious activity " to be " performed in spare time " Similarly, for some clinicians teaching has come to be primarily a verbal by-product of the concomitant care of their patients, delivered to a group of unnamed students Yet the interest taken in his work by the student will always be a reflection of the interest taken in him as an individual by his teachers, and in this respect a contrast to our disadvantage has been drawn between British and American medical schools The American teacher, as a rule, is interested in the individual student and

---

lon Oxford Medical Publications 1955 Pp 154 25s s no longer much interested in didactic teaching Above all (again in SINCLAIR's words) "he knows what he is trying to do, and how he intends to set about doing it" His objective if he is a preclinical teacher in any of the better schools is not to impart factual knowledge but rather to inculcate a scientific method of thought and to stimulate the student to use this so that he may learn for himself, and remain able to learn for himself Such an objective is attainable for a large proportion of students but only if examinations are not exerting on them a diametrically opposed incentive It is for this reason that in the best American schools examinations now play a very small part in the lives of students—a sharp contrast with the recent past Such examinations as remain are intended principally to augment education rather than to assess knowledge and they are no longer the main factor in deciding what the student tries to learn. Surely the time has come when we in this country should open our eyes both to the imperfections of our teaching and to possible means of removing them?

Annotations

ALBERT EINSTEIN

Einstein was one of the greatest scientists of all time Some would say that with Newton he stood above them all.

He was born in Ulm on March 14 1879, of Jewish parents. As a boy he does not seem to have made a favourable impression on his teachers—probably because of his dislike of the ordinary school discipline, his shyness, and his great desire for privacy But those who were nearer to him discovered his love of music and his promise of creative ability It is said that at an early age he learned almost unaided to solve simple algebraical problems, and that he discovered for himself a proof of the theorem of Pythagoras. There is the story that when given a mariner's compass at 5 years of age he showed profound emotion and wonder at the sight of the needle pointing for no apparent reason always in the same direction One might almost suppose that at that moment there came to his childish mind some vague foreshadowing of his life's great work—his abolition of the absolute attributes of space and time and his creation of a space time geometry which while it successfully embraced the phenomena of gravitation never fully succeeded in including those of electricity and magnetism

From 17 to 21 Einstein was a student at the Zürich Polytechnic and a year later he became a Swiss citizen and obtained a quite humble job in the Swiss Patent Office at Berne This gave him the leisure he required for developing his thoughts In his first year at Berne he began to produce papers on theoretical physics while in his third year 1905 he published three papers which fairly shook the scientific world One of these dealt with the Brownian movement manifested by microscopic particles as a result of molecular bombardment and paved the way for the only really direct proof of the existence of molecules Another was concerned with the photo electric effect and involved a completely revolutionary advance in Planck's quantum theory The third was a 30 page paper giving the full development of his Special Theory of Relativity As a result of these achievements he held between 1909 and 1913 professorships in Zürich and Prague; and in 1914 he went to Berlin as professor of physics and director of the Kaiser Wilhelm Institute for Research During these years he had been working on an extension of his Special Theory and finally after many failures and disappointments, he published in 1915 his greatest masterpiece, the Generalised Theory of Relativity—his theory of gravitation

In 1933 Einstein left Berlin as a result of the Hitler purge and after spending some months on the Continent, emigrated to the United States where he became a professor of physics at the Institute for Advanced Studies in Princeton There up to the time of his death he was occupied in trying to develop a further extension of his theory which would embrace the electromagnetic as well as the gravitational field. But though he believed that he had obtained partial success, the complete solution always eluded him About 1940 he became an American citizen

It is often supposed that Einstein's greatness lay in his mathematical ability That was not so Though he was judged by the highest standards, a fine mathematician there were others even in his own generation who were much greater His surpassing brilliance was in the field of theoretical physics and his stupendous imagination and piercing insight enabled him to probe its foundations to discover the flaws which were there and to rebuild from the very bottom the whole structure anew To do this he had to employ the most complex mathematical machinery but that machinery was not of his own making It had been developed by others—by Gauss Minkowski Riemann Ricci and Levi Civita

It is remarkable that many of the fundamental conceptions he put forward during the development of his theories are essentially simple—so simple that generations of thinkers had passed them by without appreciating their significance The idea of the absolute simultaneity of separated events had passed unchallenged since the days of Newton Yet Einstein saw that in terms of physically possible observations the idea was meaningless, and that the difficulty could be over-come only by completely changing our ideas on space and time This he did and then went on to develop his Special Theory of Relativity Again at the outset of his work on the Generalised Theory he was struck by the curious coincidence that the inertial mass and the gravitational mass were always proportional to one another This fact together with the similarity between the effects of a gravitational field and those of an accelerated coördinate system suggested to him that there were strong a priori reasons for supposing that an extension of his theory to include accelerated motions might be achieved if the manifestations of gravitation could be shown to arise out of the peculiar geometrical properties of space time Although in both these cases a vast labour lay between the first idea and the developed theory the ultimate victory could scarcely have been achieved without these flashes of inspiration of which there were many more examples

It has been said that if Einstein had never written a word on Relativity he would still have been one of the foremost theoretical physicists of his generation his revolutionary contributions to the quantum theory in its earlier phases would have sufficed to ensure that The greatest bugbear of modern science is its dual character Microscopic physics has to be expressed in terms of quantum theory which depends on laws of probability while macroscopic physics has to be expressed in terms of relativistic theory which is governed by the laws of causality And the two theories appear completely incompatible Most scientists believe that ultimately when the two become merged into one the underlying theory will be of the probability type, while the relativistic theory for large scale phenomena will be found to be derivable from it statistically Einstein took the opposite view He felt that the probabilities uncertainties and discontinuities of the quantum theory while providing a useful tool in the present incomplete state of knowledge was fundamentally unsatisfactory and represented only a passing phase in science He felt that the all-embracing theory would be found to be based on the laws of causality And it was his belief that the first step towards this larger synthesis was a further extension of his Generalised Relativity which would embrace in a space-time geometry not only gravitation but electromagnetism

In spite of his retiring nature Einstein played a leading part in the general affairs of the world in which he lived He was an outspoken and courageous pacifist, and during the first world war he was one of the few German intellectuals who refused to sign a manifesto in support of German militarism instead he issued one of his own protesting against it In later years he vigorously opposed Hitler and Nazism and their anti-Jewish activities, and it was in support of his fellow Jews that he thrust aside his shyness and made the few public appearances of his career

SUCROSURIA

ONCE sucrose is absorbed into the blood-stream it is not metabolised but excreted in the urine But sucrose is not a reducing sugar and so will not be detected in the urine by routine chemical examination Reports of patients with sucrosuria are very rare In 1939 Elmer et al [1] described a single patient and reviewed earlier reports They concluded that there were two varieties of the condition in adults in "endogenous" sucrosuria, which has been noted in patients with pancreatic disorder, the sucrosuria persists even though sucrose is absent from the diet, and in "exogenous" sucrosuria, as in their own patient, sucrose in the diet is either poorly converted to glucose and fructose in the intestine or is absorbed unsplit by the gut wall

Infants and small children are less tolerant of sucrose than adults, and Lahdensuu [2] showed by tolerance tests that the intestinal absorption of sucrose, and hence sucrosuria, is increased by feeding sodium bicarbonate and lessened by feeding hydrochloric acid In 1910 Reuss [3] had noted that sucrosuria was common in infants who had had gastro enteritis, and this he attributed to increased permeability of the intestinal wall Obviously, therefore, the significance of sucrosuria in infants and young children must be carefully evaluated Moncrieff and Wilkinson [4] quote paper-chromatography observations by Woolf that not more than 30 mg per 100 ml of urine is found after meals in normal infants and children Any considerable amount of sucrose in infants and children, therefore, is likely to mean an anomaly either of sucrose digestion or of intestinal permeability Reiner and Weiner [5] described a 7-month-old boy who had temporary sucrosuria during a febrile illness At the age of 18 months the boy was mentally defective Moncrieff and Wilkinson [4] have recorded three cases—a girl of 30 months, a girl of 18 months, and a boy of 18 months—in which sucrosuria up to 150 mg per 100 ml was present on a normal diet All three children were mentally defective and had hiatus hernia These children excreted sucrose, lactose, fructose, and occasionally glucose in abnormal amounts when fed sucrose and lactose, but sugar excretion was normal when they were given glucose, fructose, and lactose Sucrose, with glucose and fructose, caused only a slight increase in glucose excretion It appeared, then, that it was lactose and sucrose together in the diet which caused the abnormal increase of urinary sugars Moncrieff and Wilkinson believe that the anomaly is one of intestinal absorption, since there must be some splitting of sucrose to explain the appearance of glucose and fructose in the urine after a test dose of sucrose They were unable to get any specimens of intestinal juice during life, but in one child a post mortem specimen was found to split sucrose and lactose The hiatus hernia, though perhaps part of the syndrome, cannot be the cause of the sucrosuria, for a number of children with such hernia were found to have normal sugar metabolism Again, it is tempting to attribute the mental defect to the sucrose in the blood, but in the one child who died the brain showed a number of developmental abnormalities

This is an interesting new field of study, not only for its clinical significance, but for the light it may throw on sucrose tolerance in normal infants and children

AORTIC STENOSIS

SURGICAL treatment of aortic stenosis [1,2] has quickly followed the successful relief of pure pulmonary stenosis, but the indications for operation are not yet defined. Bergeron and his colleagues [3] have recently analysed 100 cases of aortic stenosis to see whether the severity of the lesion and its prognosis could be predicted from clinical findings alone In all cases the diagnosis was confirmed at necropsy, and associated valvular lesions excluded, while three grades of stenosis—mild, moderate, and severe—were recognised from post-mortem measurements Bergeron et al conclude that assessment of the severity of the lesion from clinical findings is unreliable and difficult, for the severity did not necessarily match the signs except when they found the classical picture of systolic murmur and thrill, diminished second sound, and a small pulse, which almost always indicated severe stenosis Conversely, severe stenosis could be present with a systolic murmur alone, which was sometimes apical rather than basal In 11 cases, only 2 of which had mild stenosis, no murmur was heard at any time, which added to the difficulties in diagnosis, this was not just a terminal event due to extremely low output, since 2 patients only were in failure The second sound was unreliable as a guide to diagnosis or severity, but a pulse pressure of 30 mm Hg or less usually indicated severe or moderate stenosis, but severe stenosis was not ruled out by higher pressures Many patients remain symptom-free throughout their life or for many years. On the other hand, the onset of auricular fibrillation, heart failure, cardiac pain, or syncope were grave prognostic signs in Bergeron's series, for 75% of those in whom fibrillation developed, and 50% of those whose hearts failed, died within a year If two or more of these manifestations coexisted the prognosis was much worse But for most patients the outlook was good, and the mean age of death in the series was nearly 69

These findings agree with those in other series [4,5] and emphasise the many points of similarity between pure aortic and pulmonary stenosis, particularly as regards the murmur and second sound, and the long survival without symptoms in many cases This is not surprising since the two lesions are anatomically rather similar, and they both cause simple obstruction to the outflow from their respective ventricles At present the reasons why a ventricle should suddenly fail after overcoming an extra load for so long are imperfectly understood, although inadequate blood-supply to the myocardium from associated coronary narrowing or the stenosis itself must be important factors It is therefore impossible to judge when failure is imminent until symptoms have appeared. Campbell [6] has pointed out that a considerably raised right ventricular pressure in pulmonary stenosis may be an indication of the need for operation, even in the absence

of symptoms; but in aortic stenosis right heart catheterisation cannot measure left ventricular pressure Whatever the final view on the right time for operation in aortic stenosis, all the evidence points to a rapid downhill course when major symptoms appear, and there is always the slight risk of sudden death without warning

SPENDING ON HEALTH

A CONCERN for health rather than ill health is seemingly a hard thing for a health service to achieve Prof Thomas McKeown speaking at the Royal Sanitary Institute s congress this week pointed out that not only the public but members of Parliament think that the health of the country depends mainly on the adequacy of the medical service and especially on the hospitals yet this view is not based on examination of the evidence There is a deep rooted reluctance among us to admit we cannot pay for everything that might conceivably help a sick person but if we go on trying to develop the medical services along traditional lines it will cost far more than we can afford Is there for instance any prospect of creating a satisfactory service for the mentally sick and the aged and chronic sick at a price which we shall be able to pay ?

The value of a medical service in Professor McKeown s opinion can be measured reasonably precisely in terms of mortality and morbidity rates and one way of judging the effectiveness of medical measures would be to discover the degree in which at a given cost they contribute to the extension of life or to making life more free from illness This cannot be done at some given moment once and for all what is needed is continuous appraisal such as is practised in any large industry which has to relate its affairs to changing conditions In any case the curative services he holds have contributed relatively little to the falling mortality and morbidity of the past 150 years the decline can be much more probably attributed to an improvement in living conditions, possibly influenced to a small extent by medical teaching Indeed it is not so much what happens when we become ill that matters we owe our longer healthier lives to the fact that in general we become ill less often Our hopes for the future then he thinks, should be vested largely in the prevention of disease, because that has been the main source of improvement in the past He does not suggest however that the preventive methods which have so far been successful if merely extended would serve to deal effectively with modern problems: in fact, he declares they will not Thus traditional methods may still reduce infant mortality in areas where it remains high but they cannot affect infant deaths due to congenital malformations or to prematurity—problems calling for a kind of research not traditionally regarded as in the field of public health Similar considerations apply he suggests to mortality in general: preventive medicine in fact should no longer be linked in our minds only with infectious diseases It must take within its scope the whole of human disease and must cease to think of bacteriology as its parent discipline

BLAND-SUTTON

John Bland Sutton was a great man—great enough to achieve distinction despite the opposition that blocked the progress of the pioneer He was born on April 1 a hundred years ago and it is fitting that his centenary should have been commemorated at the Middlesex Hospital and Medical School where he spent the whole of his professional life He was the first graduate of the school to be appointed a member of the honorary staff and of the many outstanding men who have been associated with the hospital he is perhaps the one who has endeared himself the most and whose influence has been greatest. It was his gift of the Bland Sutton Institute of Pathology since emulated at many other hospitals, that opened the way to the scientific development which has enabled the Middlesex to reach its prominent position among teaching schools The extent of the advance stemming from his inspired gift was well shown by the scientific exhibits presented in the Medical School on April 22 to illustrate the work now in progress. His original institute, to which are now added three others—the Barnato Joel Physics Laboratories the Courtauld Institute of Biochemistry, and the Institute of Clinical Research—together with six other professional departments arranged such a display as would have made him very proud But the exhibit which probably attracted most attention was the collection of Suttoniana which showed him as a man the diversity of his interests and above all, his humanity

Many still very much among us worked with Bland Sutton in the prime of his life, and three of the most distinguished Sir Gordon Gordon Taylor Sir William Gilliatt and Lord Webb Johnson, gave reminiscent addresses Bland Sutton was a man of Napoleonic mien and of the same assurance and he made his way with equal determination Choosing surgery at the start of his career he approached it by the customary path of the dissecting room and the post mortem room, but it was his genius to add the mortuary of the London Zoo It was experience in the latter that gave him the knowledge of comparative anatomy and pathology which contributed so much to his scientific eminence In this respect, and in the diversity of his interests he must have resembled John Hunter more closely than any surgeon since He was as great a surgeon as he was a man certain in approach as only an anatomist can be dextrous and unbelievably quick—the tip of his knife seemed as sensitive as the tip of a finger He was the first at any rate in England to excise a duodenal ulcer, the first to make a thoraco abdominal approach and the first to perform a hysterectomy for fibroids—a proceeding that raised a storm of protest Although he abhorred the idea that he might be thought a gynæcologist he was best known for his work in the pelvis He raised pelvic surgery to a new level and created a school of pelvic surgery Victor Bonney and Comyns Berkeley were his pupils

Bland Sutton is fast becoming a legend and like so many legendary figures he is surrounded by stories which illustrate the breadth of his character They are kindly stories for he was much loved A woman on whom he had operated later had occasion to consult another surgeon about a different problem An X ray film then showed half a needle embedded in the abdominal wall The patient chanced to see the film and when she seemed troubled the surgeon was quick to assure her that the needle was not the cause of her symptoms. That s not what I m worrying about ' she replied It s Sir John please don t tell him he d be so concerned

FUNCTIONAL SYMPTOMS IN ORGANIC DISEASE*

A. BARHAM CARTER
M.D. Camb., M.R.C.P., D.P.M.
PHYSICIAN, ASHFORD HOSPITAL, MIDDLESEX; ADVISER IN NEUROLOGY TO THE WAR OFFICE

It is hard enough to learn to distinguish the organic symptoms one from the other and to evaluate their importance; it is still harder to distinguish the organic from the functional. But these tasks are as nothing compared with the problem of the patient with an organic illness who produces functional symptoms which may modify and mask the progress of the underlying disease. This kind of case gives rise to more errors of diagnosis among good doctors than any other. Because it is rarely recognised as a problem in the teaching hospitals, the student is not prepared for the possibilities that will confront him in his practice; and even wide experience is often fallacious.

A clear definition of the word "functional" is necessary. It is here used to describe only symptoms produced by the emotional response of each patient to his illness, and is not used, as some authors use it, to describe organic and psychoneurotic symptoms of a similar type which interfere with the physiological functioning of the body. This latter use of the word can unfortunately be made to embrace so many general symptoms, such as dyspnœa, insomnia, and dyspepsia, that its original clarity of meaning becomes obscured. Whether "functional" is the best descriptive term for psychoneurotic symptoms associated with organic illness may be debatable; what is more certain is that most doctors know exactly what is meant by the phrase "functional overlay," and it seems more sensible to use words in their generally accepted meaning than to restrict their use to their original etymological definition.

What produces this difficult combination of symptoms? I think there are two main factors. First, this type of symptom may be due to a constitutional inability to accept or deal with the illness or its consequences. Secondly, it may be due to the effects of organic illness on a normal, or only slightly vulnerable, personality. A long, painful, recurrent illness, perhaps not well understood or managed by the doctor, may break the patient's morale. Ill-advised discussions at the bedside may start a train of obscure symptoms. Illness may bring domestic or financial changes which make the patient's attempts at adjustment almost impossible.

A functional symptom may appear at any stage of the illness, though often it shows itself as a prolongation of an organic symptom. It tends to appear suddenly and dramatically, but it is usually connected in the patient's mind with the original illness. This makes it all the more difficult to diagnose. I will now describe some examples in detail.

MOTOR DISTURBANCES

Aphonia

In patients with acute laryngitis the loss of voice may continue beyond the expected time of recovery. In organic illness it is fair to call this a functional symptom, though it is only the perpetuation of the symptom of the organic disease. It is always painless and is fairly easy to diagnose because:

(1) The patient can cough normally, though he is apparently unable to phonate.

(2) On inspection the cords show adductor paralysis on attempted phonation, with normal movements otherwise.

(3) Electric stimulation to the front of the neck will produce normal phonation.

Treatment is by active strong suggestion, stimulating the back of the throat, and making the patient phonate by gagging. This is usually one of the easiest and most satisfactory symptoms to treat.

Vomiting

In my experience this functional symptom arises only in the hysterical personality, and is not connected with the anxiety factor of organic illness. So far all my patients with this symptom have been women, and the illnesses have been of a relapsing nature, such as peptic ulceration, ulcerative colitis, rheumatoid arthritis, and sometimes pregnancy (though perhaps I should not describe this as an organic relapsing illness). It is also seen after abdominal operations and may be very troublesome.

This type of vomiting does not interfere with appetite, is effortless, and is unaccompanied by nausea. There is very little dehydration and no weight loss, though the patient will tell you "I bring everything up after every meal." Absence of ketosis, despite the vomiting, is another point; and if you watch the patient vomiting you will find no pallor, sweating, or tachycardia. It will often be surprisingly difficult to obtain a specimen for examination. Presumably only part of each meal is vomited, and the obvious well-being of the patient often makes diagnosis easy. It is of the utmost importance to make sure that you are not dealing with pyloric stenosis, cerebral tumour, or uræmia.

Treatment is difficult. Starvation usually helps, but I often find myself saying: "Your vomiting does not matter because you appear to be in good health in spite of it, and your stomach will adjust itself once you start work." I am careful not to ask them whether they have been sick.

Pyrexia

If a patient with an illness such as pulmonary tuberculosis, subacute rheumatism, or simple respiratory infection continues to have fever long after other signs have disappeared, the possibility of artificially produced pyrexia will arise. Needless to say, *it is unwise to make this diagnosis until one is sure that it is correct.*

Significant points are a grossly swinging temperature out of all proportion to pulse-rate, sweating, and colour, a continued fever with a persistently normal sedimentation-rate, and a fall in the temperature when taken under strict observation.

The pitfalls are latent pulmonary tuberculosis with a normal sedimentation-rate, drug fever, anæmia, and carcinoma, particularly hypernephroma. My own opinion is that these people are malingerers, and that all the grosser forms are due to radiators, hot-water bottles, hot drinks, and friction of the thermometer bulb; but I must admit that in some cases I have not found the explanation. The only treatment needed is to say that the temperature does not matter. So far all my cases in this group have been nurses.

Paralysis

Paralysis usually occurs after injury or during an epidemic of poliomyelitis. The traumatic cases are often associated with desire for compensation or fear of incapacity, and the infective cases with straightforward terror of the disease itself. In compensation cases the paralysis does not clear up at once after satisfactory settlement, unless the patient is malingering, but takes between two and three months to improve. In the poliomyelitis group I have yet to see a child develop hysterical paralysis through fear of the disease. But I have seen the opposite of this—a pathetic child of 10 pretending that its affected arm was strong, so as to avoid being sent to hospital away from home.

How can we recognise this functional weakness? First, the weakness is often associated with sensory loss affecting the whole limb Secondly, the examiner experiences, on gripping the affected hand, a feeling of power intermittently withheld and on gripping both hands together the normal hand will be weaker than when gripped alone Thirdly the wrong muscles can be felt to contract, and involuntary contraction is strong where voluntary contraction is weak. For example a man complains that he has no strength at all in his right leg if a hand is placed under the right heel while he is lying in bed and he raises his normal left leg against thigh pressure, a strong downward thrust of the right heel is felt There is also absence of muscle wasting while reflexes and electrical reactions are normal

---

* An address given to the South Wales branch of the British [illegible] Association on April 3, 1954.

A nurse aged 23, had poliomyelitis affecting the left arm and leg In the second week of her illness when she was afebrile and doing well, paralysis of the right arm developed overnight and I was told that the condition had spread This was unusual in my experience and on examining the arm I found all the positive signs of hysterical weakness. I thought it important to get function back, and with a dose of thiopentone and suggestion her power returned I asked her afterwards why she had been so upset by her illness that she had believed her unaffected arm to be paralysed, and she told me that she was in a quandary She felt she should return home for the sake of her mother who had been left alone owing to a brother s call up but she was happy in her nursing and hated the idea of giving it up All was settled in the best possible tradition of British compromise by her taking a part-time nursing position near home

How should these hysterical palsies be treated? I think the doctor should explain to the patients that their memory for moving the limb has been lost because of some worry, trouble or anxiety, or because of the effects of the accompanying organic illness. After this suggestion under thiopentone is easy and usually successful, and the confidence thus engendered often helps these patients to confide their troubles freely

SENSORY DISTURBANCES

Functional symptoms occurring in physical disease may besides affecting motor function interfere with sensation. There may be either loss of sensation or increased sensibility to pain with a lowered pain threshold

Loss of sensation —Anæsthetic areas appear, usually peripherally or else down one side of the body, which do not correspond to the distribution of sensory nerves nor spinal-cord segments. The classical types are called glove and stocking in distribution The only organic diseases which produce a similar peripheral sensory loss are peripheral neuritis, where the tendon reflexes are sent and obliterative vascular disease where arterial ulsation is absent or diminished In the hemianæsthetic ses the loss of sensation is exactly midline; in the ganic diseases it does not reach the midline because overlapping supply from the normal side

I do not think any treatment is needed beyond pointing out that the symptom is of no importance and that it is not uncommon or unusual An assurance that the doctor has often seen this sort of thing before is useful

Pain —The most difficult functional symptom in organic disease is pain It can be a great trial and responsibility to everyone and I have made more mistakes over this symptom than all the others put together

I am sure that all pain should be regarded as organic until proved otherwise The commonest sites for functional pain are the head the back, the chest and the abdomen—in that order More and more organic abnormalities are being adduced to explain pains which [illegible]ty years ago I regarded as functional—fibrositis of the [illegible] temporal arteritis, spondylosis prolapsed intervertebral disc vasomotor instability—and I believe that some of these really exist and may produce pain

One or two clues are useful The pain, if not organic is described dramatically with a wealth of detail, and sometimes with bizarre distribution The pain is continuous "it never leaves me doctor," and (the most important simple diagnostic point of all) "nothing relieves it" This non response to good analgesic drugs is most helpful but not unfortunately completely reliable, because not only do neurotic symptoms occur in organic disease but organic disease occurs in neurotic people

I well remember a shockingly hypochondriacal aggressive difficult woman of 47 who plagued my outpatient department for three years with her complaints of headache like a heavy weight, doctor right in the middle here splitting my head open. She was admitted reasonably careful investigations revealed nothing and she was thankfully discharged Two weeks later she died suddenly while shopping and necropsy showed a tuberculoma of the falx between the two hemispheres. How right her description had been, and how wrong my assessment of her last illness.

Treatment of correctly diagnosed functional pain in organically ill patients must be sympathetic and unhurried We should explain that long-standing and relapsing illnesses may upset the nervous reactions of even the best intentioned patients We should not hesitate to assure them that they are having the best care and the best advice possible Only in this way will any benefit accrue to these difficult patients who are so exasperating and so time-consuming but often so frightened, so confused about themselves, and so unhappy Of one thing I am sure—so-called firmness of treatment can do nothing but harm The wisecracks and cynical remarks still made about these people reflect only on their makers who fail to realise how many symptoms are produced by doctors

CONCLUSION

In trying to show how some individual symptoms can be diagnosed as functional, and separated from accompanying organic disease I have emphasised some positive signs of this type of symptom rather than the absence of organic signs Suspicions will often be aroused by the general attitude of your patients I have found that the onset of a functional symptom commonly increases their demanding tendencies so that they lose the previous quiet acceptance of your skill and treatment that usually accompanies uncomplicated organic illness Do not blame them for this change—partly because you may be mistaken and then your blame will rebound on your own head but chiefly because your own annoyance, however justified, cannot help them and will cloud your judgment.

The great tragedy of course is to miss the organic. Therefore the physical examination of a patient ill for a long time must never become cursory and each examination should be as thorough as if it were the first Always remember that if you miss anything it is not because your intellect is failing but because you are not on the look-out for it.

NEW PROSPECTS IN RADIOTHERAPY

15 million volt Linear Accelerator at Barts

THE steady (and some may say sinister) advance in our knowledge of the properties of the universe went forward another step in a ceremony this week at St Bartholomew s Hospital in London On April 27 the Duke of Gloucester president of the hospital set in action a new 15 million volt linear accelerator which will in the next few years add considerably to our understanding of high-energy radiations and their effects on living tissue

To keep the hospital in the forefront of progress in radiotherapy (a position it has long held) the governors decided, in 1950 to install a machine that would help to expand the theory and practice of radiotherapy In the end the choice fell on the 15 million-volt linear accelerator—a machine which combines a high energy with a high intensity of radiation A contract was then placed with Philips Electrical for the machine to be built at the Mullard Research Laboratories Like its simpler forerunner, the X-ray tube, the linear accelerator is primarily a means of accelerating a stream of electrons The advantage of the new accelerator is not so much the high energy it imparts to the electrons but the great number of electrons it can handle Other types of accelerator, like the betatron or synchrotron, produce radiations of even higher energy, but their output is generally too low to make them a useful tool in routine radiotherapy

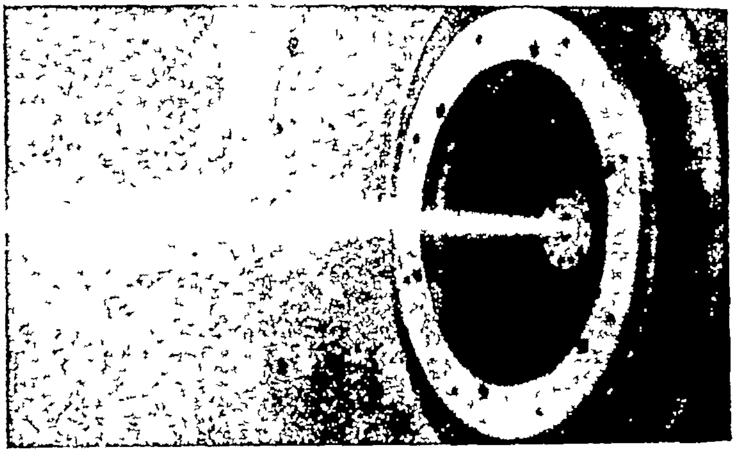

Fig 2—The electron beam leaving the accelerator

RESEARCH POSSIBILITIES

The treatment of malignant disease with X rays of high energy is, of course, one of the primary objectives, but the accelerator makes it possible to use either electrons or neutrons to irradiate a tumour Little is yet known of the effect of bombarding living tissue with these particles at high speed and in large quantities Much experimental work must therefore be done before the therapeutic possibilities can be assessed The neutron (being an uncharged particle) is difficult to keep track of, and uncertainties about dose-rates have hitherto deterred radiologists from attempting to extend the early work on neutron therapy The results of neutron therapy may be quite different from those produced by X rays, and this is perhaps the most interesting part of the new country that the accelerator will explore For one thing there is some evidence that it may be *possible to localise the action of the neutrons to* definite selected regions of the body As for electrons their range of penetration in tissue is limited (it is about 3 inches for 15 million-volt electrons), and under certain circumstances this property may be an advantage

But the new machine will perhaps be of even greater significance for the fundamental research that is planned into the biological action of radiations In many other ways the fearful prospects of the mismanagement of atomic energy are now all too clear, but we know very little about what an *ionising radiation* really does *in its* destructive course through a living cell If we did, it is just conceivable that we might be able to do something about it *The linear accelerator is particularly* suited to investigations of this kind, mainly because it emits its electrons in short bursts of enormous intensity, each lasting about a millionth of a second The dose rate during a pulse can reach something like 700,000,000,000 röntgen per minute All this means that the development of the changes in the cell can be followed with much greater precision than is possible with low-output machines and relatively long exposure times

For the next few years the accelerator at Barts will be devoted entirely to research on the biological action of radiations and on new techniques in radiotherapy During this time very few, if any, patients will be treated, so the machine has been installed in a temporary building in Charterhouse Square, next to the physics department of the medical college The work here will be directed by Prof Joseph Rotblat professor of physics in the University of London

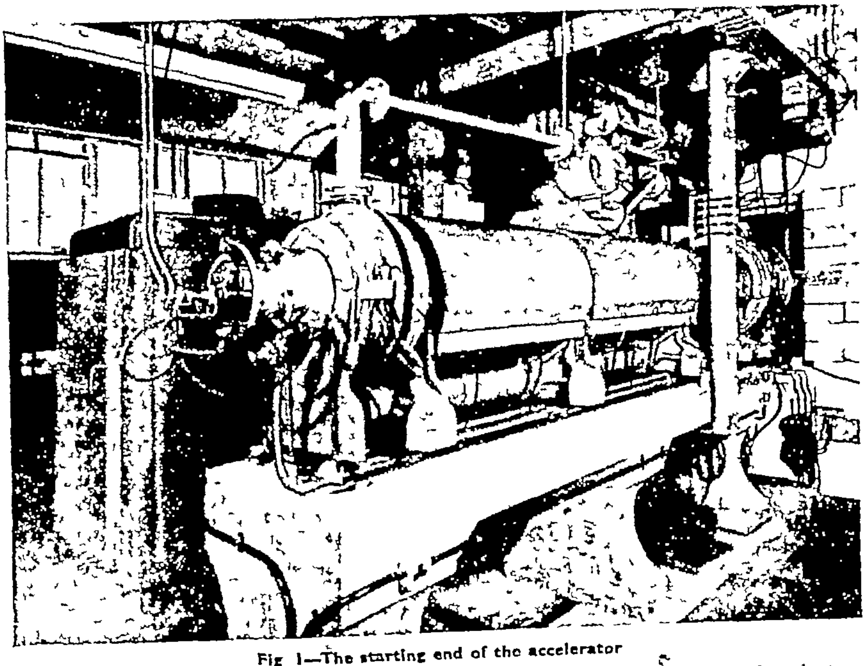

Fig 1—The starting end of the accelerator

The two vertical cables at the left hand of the machine run down to the electron in, behind which stands the cabinet housing the modulator The magnetron valve is en above the first section of the waveguide, and from it a system of pipes transmits [illegible] wave to the waveguide and back again The X ray head and the rest of the [illegible] e beyond the wall on the right

THE MACHINE

The principle of the accelerator is the use of a radio wave to pick up and accelerate electrons in an evacuated tube

An electron gun gives the electrons an initial velocity about two fifths that of light. This is achieved by applying a voltage of only 50 000 volts, which is the highest voltage used in running the accelerator. The electrons are speeded up by a radio wave travelling along a tube 20 feet long called a waveguide (its outer cover is seen in fig. 1). The velocity of the wave can be varied by diaphragms placed at intervals inside the waveguide. The wave can be made to pick up the electrons and deliver them at the other end of the tube with a velocity 90-95% that of light.

A valve called a magnetron supplies the waveguide with high frequency radio waves in short pulses. The power in the pulses is very high, about 2000 kilowatts, and about 40% of this can be delivered to the electron beam. The power from the A.C. mains is transformed by a modulator to produce high voltage pulses for the magnetron.

In the X ray head, where the electron beam emerges, there is a magnet which can bend the beam through 90°. The whole head can be rotated through an arc of 140° so that the radiations can emerge in any direction from 20° on one side of the downward vertical to 30° above the horizontal. The head contains a target holder which can be set in any of three positions: (1) no target (electron beam only), (2) platinum disc (X rays), and (3) uranium cylinder (fast neutrons).

The very high output of the machine raises difficulties in timing the exposure. To overcome this a special electronic device was designed and built in the physics department of St. Bartholomew's Hospital Medical College by means of which the exposure is terminated after any predetermined number of pulses from 1 to 10 000. In many radiobiological experiments exposures of a single pulse will be used.

The photograph we publish (fig. 2) illustrates more vividly than anything else the formidable power of the accelerator. The emerging electron beam is so intense that the area of ionisation stands out as a bright pencil of light, which rapidly fades away as the electrons are scattered by a relatively short passage through air.

RHEUMATIC UNIT AT EDINBURGH

A RHEUMATIC unit with 30 beds was started in the Northern General Hospital, Edinburgh, in 1947, and since 1948, when the hospital was taken over by the South Eastern Regional Hospital Board, it has been a regional centre for the diagnosis and treatment of chronic rheumatic disorders. At the instigation of Sir Stanley Davidson the University of Edinburgh created the whole time post of a senior lecturer in rheumatic diseases by whom the unit has been directed.

At first little in the way of research could be undertaken because both accommodation and staff were insufficient; but in 1949 support came from the Nuffield Foundation, which had just formed a clinical trials committee to administer a fund provided by Captain Oliver Bird, primarily for investigation into the prevention and cure of rheumatism and for relief of incurable cases. The Foundation made a grant permitting the employment of a clinical research fellow, a secretary, an almoner, and a clinical photographer, and the board of management found additional accommodation for the outpatient department and for research. With these facilities the unit has participated in the initial trials in this country of corticotrophin and cortisone and has made a detailed study of medical and social problems in rheumatoid arthritis. It has had continued financial help from the Nuffield Foundation and grants from the Medical Research Council, the Empire Rheumatism Council, and the Advisory Council of Medical Research (Scotland).

Last Saturday Commander T. D. Galbraith, Minister of State for Scottish Affairs, opened a new building adjoining the unit's wards.

It consists of two single storey blocks connected by a glass link which forms the entrance hall. One block is devoted to clinical work and laboratories, and the other houses the staff rooms, offices, and photographic suite. The plan is L-shaped and the main section contains six consulting rooms each equipped with examination couch, wash basin, built in blood pressure machines, and X ray viewing boxes. A waiting space open to the corridor is situated in the centre of the consulting area with dressing cubicles and toilets adjoining. Two laboratories and a conference room are at the end of this block, the laboratories having metal unit fitments which can be interchanged or added to later. There is also a small animal house.

The building is "contemporary" in design, but the construction is traditional. Internally the maximum use has been made of natural timbers, which are used to offset rich applied colour on various wall surfaces. A degree of informality is obtained by the extensive use of indoor plants and flowers. The furniture and fittings have been chosen by the architects, and are mainly of Scandinavian manufacture and design.

The total cost of this building, which was completed in ten months, was £27 000, inclusive of furniture and fittings. The Secretary of State for Scotland has leased the site to the Nuffield Foundation for five years, after which the site and the building will revert to the hospital as a gift from the Foundation. In addition the Foundation has promised £38 000 from the Oliver Bird Fund to meet the running costs during these five years.

Sir GEOFFREY GIBBS (chairman of the managing trustees of the Foundation) presided at the opening, and those present included Captain Bird. Besides Commander Galbraith the speakers were Sir HUMPHREY BROUN LINDSAY (chairman of the regional board) and Dr J. J. R. DUTHIE (director of the unit).

Medicine and the Law

Drug-addiction as "Cruelty"?

THE wife of a medical practitioner was given pethidine by a specialist at a time when pethidine was thought to be non habit forming, and became addicted to it. She importuned her husband for it by day and night, disturbing his work and his rest. He was advised not to give her that or any other drug involving injection, but he did not cease to do so. In May, 1952, the wife was certified and admitted to an institution, but in September she was discharged "relieved". She had no more drugs until in May, 1953, her husband gave her 'Omnopon' by injection to relieve pain from a sinus. She had to be certified again in July, but shortly after she was discharged 'recovered'. After that she worked as matron at a school and continued to behave normally without resort to any drug.

While she was under treatment her husband told her that he did not intend to live with her again, and in November, 1953, she filed a petition for restitution of conjugal rights. By his answer the husband pleaded just cause for refusing to live with her, and asked for a divorce on the grounds that she had become a drug addict and her resulting conduct towards him constituted cruelty. Mr Justice Wallington granted the wife the decree asked for and rejected the husband's prayer for divorce. The husband appealed.

In the Court of Appeal on April 20 Lord Justice Hodson said that the vital matter on the charge of cruelty arose in May, 1953, when the husband gave his wife omnopon knowing that it had a morphine basis and that his wife had been a drug addict, and having been warned against the very course he took. The conduct thereafter of which he complained seemed to follow from his act almost as night followed day. It was impossible to hold that conduct against the wife as cruelty by her.

Then it was claimed for the husband that although he had failed to establish cruelty the court ought, for a time at least, to withhold a decree for restitution of conjugal rights because in drug addiction cases there was undoubted danger of a relapse, and that risk existed here because the husband was a doctor and if his wife came to live with him again she would have access to drugs But the husband, in order successfully to resist a decree for restitution would have to show that it would be wrong to treat him as a deserting spouse (Russell *v* Russell [1895] pp 315, 334) The husband in this case could not show that The wife had shown herself willing to do what she could to rehabilitate the married life, and there was nothing to prevent an order being made in her favour The appeal should be dismissed

Lord Justice Parker gave a concurring judgment The Master of the Rolls (Sir Raymond Evershed) also agreed, but added that the husband's past acts in administering these drugs would not necessarily disqualify him from any relief in the future if the wife should come back and again succumb to any relapse and he should find he could not go on living with her The appeal was dismissed

Baby Dies after Fumigation of Pram

When an Oldham family moved into a corporation prefabricated house their hard furnishings, including the baby's perambulator, were fumigated with hydrogen cyanide[1] Later the baby became ill and died, and the parents and a daughter aged 2 had headaches and sickness Their pet budgerigar also died A forensic report said that traces of cyanide were found in the lungs and other organs of the baby and also in the dead bird At the inquest a pathologist said the presence of poison was a factor in causing the child's death He had also found evidence of dysentery In answer to a question, he said he did not know whether the child would have died of cyanide poisoning if she had not had dysentery death was due to a combination of the two The child's mother told how she had handed the perambulator, containing a mattress and clothing, to corporation employees She was not told to remove the mattress. In evidence an employee of the health department said that the family were told not to leave bedding in the perambulator Recording a verdict of accidental death, the deputy coroner found that there was no evidence of criminal neglect, but there may have been some "slip up" by a public-health employee

Hypersensitivity to Penicillin

A woman of 73 died within ten minutes of receiving an injection of penicillin[2] At the inquest her doctor said he had given the patient penicillin before without ill effects, but this time he noticed that she became flushed and breathless a few seconds after the injection. In spite of all he did she died within ten minutes A pathologist attributed death to the intravenous injection of a small amount of penicillin, to which the patient was allergic If she had not been abnormally sensitive she would not have died A verdict of "death by misadventure" was recorded

MEDICAL OFFICERS, ALEXANDRA HEALTH CENTRE AND UNIVERSITY CLINIC, JOHANNESBURG

Alexandra Township, with its 80,000 African and Coloured people living in an area of $1^{1}/_{2}$ sq miles, lies on the outskirts of Johannesburg It is one of the few places in the Union where Africans may own land The population is changing from a rural to an industrial society, the old extended family, which provided its own social security, is breaking up and slowly being replaced by the isolated, fragmented industrial family The men are employed in Johannesburg in the factories, in businesses, as domestic servants, at an average wage of about £3 a week Many women work in the city A growing number is employed in industry but the majority are washerwomen, nursemaids, and housemaids, sleeping in servants' quarters in Johannesburg and returning to their families on their days off A sprinkling of the population are shopkeepers and professionals

The Alexandra Health Committee has an annual budget of £70,000—less than £1 per head of population, compared with the budget of £28 per head in the adjacent Johannesburg area The Health Committee is expected to attend to the usual local government functions Being mainly a nominated body it has little standing wit [illegible] ple There are no sewers, sanitation and refuse disposal are inadequate, the roads are ditches (fig 1), and the streets are unlit Because of lack of funds no fundamental measures for the control of communicable disease can be undertaken

Budget studies by the staff of the Community Centre have shown that it is theoretically impossible for an Alexandra family to subsist on the average income Once rent, food, and transport have been allowed for there is no money left for clothing, blankets, or entertainment, nor is there anything with which to meet such disasters as illness, death, or unemployment

Most families rent one small room which must suffice for all their needs The staple cereal is maize, and white bread and oats are also used widely The main meal usually consists of porridge, a little meat, and perhaps potatoes Fresh fruit, vegetables, meat, fish, and eggs are in the shops, but are expensive and little used

With both parents at work and no after school activities girls and boys bring themselves up as best they can

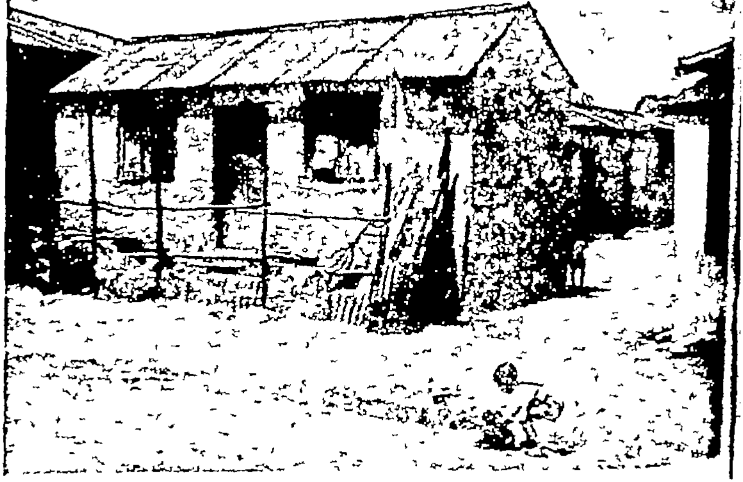

Fig 1—An average Alexandra plot seen from the street.

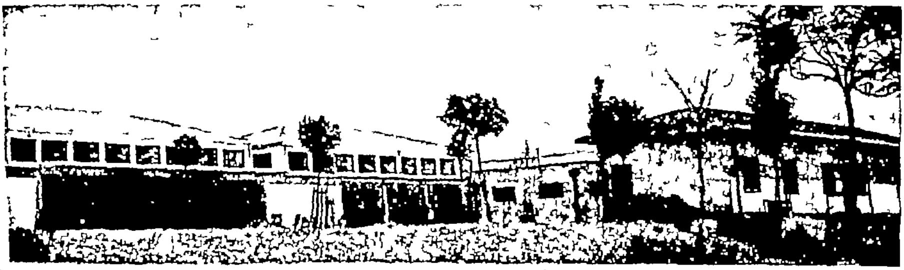

Fig. 2—The health centre and clinic.

Not infrequently the high-school girls have illegitimate babies or contract venereal disease while boys join gangs and embark early on a life of crime The police are ineffectual as protectors of life and property and at night the unlit streets have become notorious for bloodshed, rape, and robbery

Poverty and frustration and the unstable social conditions offer few incentives to sober citizens. Alcoholism is a tremendous problem, bound up with crime and venereal disease Fear of the white man his prisons and pass laws economic insecurity; fatigue from long hours of work and underfeeding—all give rise to emotional tensions.

The Health Centre

Among these 80 000 people the Alexandra Health Centre and University Clinic is the main medical service (fig 2) Administered by a board of management its funds are derived mainly from the university students rag, donations, annual contributions from the Transvaal Provincial Council and the Union government and patients fees In 1953 £20 000 was available and of this about £5000 came from patients fees Our staff consists of 4 doctors 4 sisters and 25 nurses who are helped by final year medical students who attend in groups throughout the year as part of their training

AT THE CLINIC

We hold consultations throughout the working day and we see urgent cases at any time For 1953 our statistics were:

New cases	12,500
Repeat visits	31 200
	43 700

wing to the perennial shortage of ospital beds we have to undertake more rocedures than the average outpatient linic. We have for example set aside a ecial room for patients, usually babies, ho need to be supervised over the day ere we are able to observe and instruct others in inserting eyedrops or in ving fluids to their dehydrated babies hile we record intake and output Sub taneous, and occasionally intravenous ansfusions are given where necessary e have found this arrangement invalu ble in training mothers and a help to us assessing the clinical status of patients

Within the last few years we have been ced with an ever increasing load of work he usual polyclinic system which peared to deal quickly with large umbers was tending to destroy the octor's relationship with his patient We e dealing with a people whose language istoms and economic pressures are very different from our own and they assume that we will treat them cursorily, as cases and not as people, unless we are able to show them otherwise We have found that the more prolonged and personal the relationship between patient, doctor and nurse the more we can achieve in both sickness and health

To maintain continuity between individual patients and doctors we divided the township into three areas A team consisting of a doctor a sister, nurses and students, is now responsible for all the curative casualty, and preventive work in each area Each doctor does the home visits for his own area and looks after his own tuberculous patients In this way we have gained continuity and efficiency and the patient has gained in personal contact Relations between doctor and nurse have also improved greatly as closer coöperation and understanding has become possible Team discussions in general health and nursing problems have proved valuable Our nurses are of the people speak the languages, and have much to teach us about the community On the other hand they are trained for hospital work only and there is much they have to learn about the concepts of disease health and health education We need regular and more frequent discussions but we do not easily find time for them We propose to introduce a family file system to give us a more complete picture of our regular families

The clinic is open night and day and the statistics show the heavy turnover but they do not show the amount of serious injury due to a disordered community

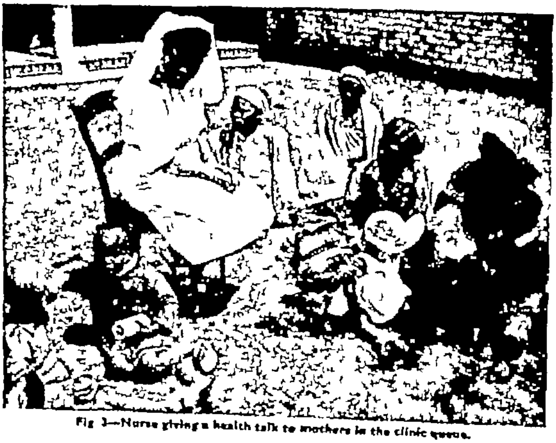

Fig 3—Nurse giving a health talk to mothers in the clinic queue.

life In 1953, first visits for dressings and injuries numbered 13,000 At weekends and on public holidays the casualty department is crowded We give emergency treatment such as intravenous transfusions for very shocked patients until we can transfer them to hospital

Curative work often drives out preventive work, and queues of patients forced us to neglect many of our intended health sessions Now we no longer give "health talks" only to the healthy and medicine to the sick We try to turn every contact with the patient into an opportunity for education We welcome re visits as a chance to consolidate our contact This attitude is difficult to maintain on crowded days, but the sick patient is peculiarly vulnerable to advice, and in so far as we have been able to carry out this policy, it has been a success

VISITS TO HOMES

Apart from midwifery calls, we made 16,500 visits to homes during 1953 Of these, the nurses made 13,500 calls, the doctors 2500, and students 1000

Nurses visit patients who have already been seen by doctors A patient with a high temperature and uncertain diagnosis whose progress needs daily reassessment, a patient with pneumonia who needs bed rest and daily penicillin, a cardiac patient who needs regular tests of digitalis and pulse checks, a patient in quarantine, demonstrations to a mother how to mix feeds or carry out treatment—this gives an idea of the range of cases on our district list Doctors and sisters take full reports from the district nurses each day and discuss their cases with them

Doctors and students do daily rounds Each firm visits weekly its own list of chronic patients, who are too ill and too disabled to come to the clinic These visits are a great comfort to the patients and give students some insight into the problems of the chronic sick

Even when the staff has been hard-pressed, we have kept up our home visits, for we are convinced that daily contact with patients in their own homes is necessary to our understanding of the people

TUBERCULOSIS

We are the tuberculosis officers for Alexandra, and this enables us to see tuberculosis as part of the general pattern of ill health

A man suffering from active pulmonary tuberculosis may be nursed at home or in "the settlement"—a cottage hospital for the tuberculotics in the township Here the patient is close to his family, in his usual environment, and the better in spirit for it The antibiotics usually render him sputum negative in six weeks, and we have found streptomycin, p aminosalicylate, and isoniazid effective even on ambulant patients at home Our patients have been cooperative and the defaulter-rate is low

In 1953, 548 new cases of tuberculosis were notified in the township Half of these were cases of primary tuberculosis, but case-finding and notification is irregular, and this figure gives no idea of the incidence of tuberculosis among children Of the adults, 80% could be classified as suffering from advanced disease at the time of notification Ignorance, superstition, fear of the disease, and fear of the stigma attached to it discourage a sufferer from seeking medical advice earlier

Thanks to government assistance, we are able to treat tuberculous patients and their families in a more integrated way than we do most of our other patients On receiving a notification, our health inspector visits the patient's home and brings back a report on the circumstances of the family It is his duty to explain to the family the disease and its implications and through h [illegible] to investigate all contacts

MATERNAL AND CHILD HEALTH SERVICE

During 1953 we delivered 2445 babies in Alexand Township, a large proportion of the infant populati All the mothers attended antenatal sessions, making average of 4 visits each Our nurses or students deliver the babies in their homes, and paid postnatal calls da for ten days The nurse explained the value of the po natal examination and the importance of the we baby sessions, and she advised each mother to attend t clinic in six weeks' time

Women pay a fee of £1, which entitles them to all t benefits of our maternity service We have tried emphasise to the mother the need for continuity maternal and child health by charging a compos fee to cover antenatal attendance, delivery, and medic care for the child up to one year of age

The midwifery service is long established and high thought of in the township, and we have had no difficul in persuading mothers to attend antenatal sessio For primitive conditions the corrected stillbirth rate (l in 1953) is good But we should like to offer mo health education at the antenatal clinics, which is t time when the mother should be taught how to look aft herself To hold our own against witchcraft and primitr beliefs, we have to teach some elementary concepts to o mothers Techniques must be explained in a way which simple yet fundamental To fill this need we ha instituted a system of antenatal home visits where t nurse goes over the talks given at the clinic We ha lately produced a simple film strip explaining the purpo of the antenatal clinic and its activities At the pos natal visit the nurse concerns herself mainly with t baby and with the establishment of breast-feedin

Successful health education requires long conta with the family, especially with the mother If she com to the postnatal clinic we know we have won her co fidence In 1953 about 66% of the mothers broug their new babies to the well baby clinic We try allow each new mother some minutes of individu discussion about herself and her family We outline t functions of the clinic, and explain the importance of t weekly dose of vitamin oil, of regular weighing immunisation, and correct feeding Each mother a baby is given a full physical examination Nurse th leads a group discussion on some of the questions th have been raised and tries to meet any difficulti (fig 3) Given time and staff, this postnatal visit c be the most important of all our contacts with patients In our experience it is a vital link in the mother's under standing of child care If the postnatal visits are hurr and neglected on a crowded clinic morning they lo most of their value

It is now left to the mother to attend the weekly ba clinic Statistics for 1953 show that 1429 mothers p first visits, and 10,941 repeat attendances were record

Our main aim in the clinic is to start the infant o sound diet We hope through the mother—the k person in the family—to change the dietary habits the whole family and eventually of the communit We teach mothers the nutritional values of differ foods, and we advise the use of cheap available fo stuffs for the infants rather than expensive brands baby foods We have tried to relate advice to act The Entokozweni Community Centre in Alexandra established vegetable clubs, a cooperative store, skimmed-milk centres When we discuss feeding proble we recommend the mothers to buy at these depots

Much of our infant mortality is due to preventa causes In the summer of 1953 nearly 100 babies d each month from summer diarrhœa Mortality in t disease is closely connected with malnutrition and wr feeding[1] Whooping cough also kills many babies He ducation must be our front line of attack on infant ortality, and the well baby clinics already play an ffective part.

---

Treatment in the Home

Poverty is inescapable in Alexandra. To improve ealth within the limits which it sets has been our main oncern.

Among the 16 000 families there were well over 00,000 calls on one or other medical service during 1953—i.e., more than one call per family per month. A reasonable charge for a private practitioner is 15s a call and 12s 6d a consultation. Few families can afford so much. In a slum population like this, the private practitioner cannot play an important role in illness neither can he strive for the frequent visits essential for health education. In Alexandra the clinic must act as the general practitioner. It must bring the family and home within its sphere and keep in close contact with the daily lives of the people.

In South Africa there is always a scarcity of accommodation in the Non European hospitals and the turnover of patients is rapid. The hospital doctor knows his patient only during the short crisis of illness he sees nothing of the events leading up to admission nor has he any control over convalescence and rehabilitation. Through our domiciliary practice we have come to understand something of our patients' background.

In hospital, the African is too often the passive recipient of injections and medicines. He learns nothing in this foreign environment of the nature of his illness, its cause and its remedy. The hospital rarely helps him to understand his disease nor equips him to deal with it.

We were first driven to nursing seriously ill patients in their homes by the difficulty we found in arranging hospital beds. Our confidence in home nursing has grown as we have realised its possibilities. To the African patient hospital is a strange world of white sheets and strange white faces. He has a strong belief that people go to hospital to die. For children particularly to leave home is a traumatic experience. We find that the care of the unskilled but carefully instructed mother will often do more for the patient than less concentrated nursing in an understaffed pædiatric ward. Cardiac patients, who used to be always in and out of hospital are now ambulant and well-controlled they have come to understand the principles of maintenance therapy and the importance of regular visits. Relapses are usually managed at home and the patients seem to be happier. The results of treating tuberculosis in the home are encouraging we have no doubt that ulter rates are reduced and that patients are more ly to undergo prolonged treatment at home than hospital. In midwifery we have found the African ther to be relaxed and coöperative and a very cient parturient at home. A good local hospital ich deals with a comparable group of mothers does better our results. When we deliver a baby at home, preserve the continuity between antenatal and postal care. The confinement is brought into proper spective as part of a process that began with con tion and will end when the infant has attained healthy ldhood. In this community which is unfamiliar h scientific medicine, domiciliary practice has much offer that the hospital does not give.

Our nursing staff is learning to contribute more to the ication of our patients. With further training in the nic and more time to spend with each family nurses can much to combat ignorance and prevent disease. rough their domiciliary visits medical students learn appreciate the potentialities of practice outside the spitals and see how environment affects disease.

We have tried to learn something about the people d with this knowledge to adapt our service to their eds. Some useful principles have emerged and the nic has improved the health of many people in Alexandra Township, but it alone cannot make Alexandra a healthy town.

We wish to thank Dr S L Kark for the stimulus of his ideas and advice Dr Cicely Williams for her encouragement and assistance and Miss Helen Navid of Entokozweni for the guidance she has given us in sociological matters. We are indebted to Dr A. D Bensusan for the photographs and to the Board of Management of the Alexandra Health Centre and University Clinic for permission to publish this report.

Parliament

Poliomyelitis Vaccine

IN the House of Commons on April 25 Mr IAIN MACLEOD Minister of Health made the following statement on the Salk poliomyelitis vaccine.

I know the whole House will wish to congratulate Dr Salk on what is clearly a momentous and historic advance in the protection of human well being. The Health Departments and the Medical Research Council have been in close touch with these developments in the United States.

For our part we shall go ahead with the increased production of the new vaccine. In this country two important firms are already arranging to do this as fast as possible and it is the Government's intention to ask these firms to sell to the Government their whole output. In due course a supplementary estimate will have to be submitted to the House for that purpose. No supplies, in any material quantity are at present obtainable from the United States. Home production should assume really useful dimensions by the late autumn and I am advised that it would be medically unwise—even if it were possible—to embark on any large-scale vaccination during the peak season of the disease which begins to end about then. It is, for example quite usual for diphtheria immunisations to be suspended during the prevalence of poliomyelitis.

Many interpretations have been put on the attitude of this country to this development. Perhaps it is as well to put the facts in plain words to the House. This new vaccine involves inoculating our children at repeated intervals with a preparation derived from the kidneys of dead monkeys. The House and the country will surely agree that we must carry out intensive tests as to the exact effects so that we can eliminate any possible dangers from it. We are already doing this. We must also make sure as we shall, that it is effective against the particular strains of the virus most commonly found in this country. indeed it is not sure yet that it is fully effective for children of about four or under where our incidence of the disease is highest and it seems it may be less than normally effective against type I of the virus—the commonest type over here.

I mention these reservations because it is important to keep the picture in true perspective. But they in no way detract from the immense humanitarian value of this great discovery or affect our determination that our own people should benefit from it to the fullest possible extent.

Mr N N DODDS: Is the Minister aware that this year the Americans are treating $13^1/_2$ million children? Would he agree that they have made excellent tests? Despite all his reservations can we have an assurance particularly as this vaccine was produced in Canada that we are not making excuses for the very slow way in which we have taken up this vaccine?—Mr MACLEOD I do not see how anyone can make a charge like that. This report came to us by air last Tuesday. A great deal of intensive work has been going on since then and in my statement I have given an undertaking that we will buy the output of the firms in this country who are making the vaccine. We will go straight ahead so that our people can benefit from the discovery as soon as possible. However I am sure it is right to mention to the House the reservations one must have on such an important matter.

Mr WALTER ELLIOT I am sure that the whole House will support the Minister in his desire to have these matters tested before embarking on any large scale treatment of the children of this country but will he publicise the lines of the tests which he is considering? If he could give some information about his investigations I am sure it would do much to reassure opinion in this country.—Mr MACLEOD: The question of research is essentially one for the Lord President of the Council but I understand that the Medical Research Council is carrying out trials in Southend Manchester Sheffield Belfast and I think Glasgow.

Mr H A **MARQUAND** Does what the Minister has said mean that he expects that by the late autumn the tests will have reached such a stage that it may be possible to begin inoculation ?—Mr **MACLEOD** Pilot batches of this vaccine are already available for testing One would hope that all the necessary testing will have been finished by the autumn and that substantial quantities of the vaccine—it is difficult to estimate how much, but between 500 and 1000 litres—will be available to us by the end of the year

Replying to a further question, Mr **MACLEOD** said that the *major limiting factor* at the moment, and for some time to come unless a new medium of cultivation were discovered, might be the shortage of monkeys The Government had already taken action to contact the government of India on the matter and the Medical Research Council had already sent representatives to Africa to study the possibility of further supplies of monkeys from there

Social Services and the Budget

In his Budget speech in the House of Commons on April 19, Mr R A. **BUTLER**, the Chancellor of the Exchequer, said that the bread subsidy cost £41 million, and the welfare subsidies, including children's milk and so forth, at least £36 million At the beginning of 1954–55, apart from the Exchequer contributions to the National Insurance Funds, the social services were expected to cost £1260 million They had, in fact, cost £1278 million, and for 1955–56 it was expected that they would cost £1315 million Comparing the original Budget estimate for last year with the estimates for 1955–56, the health service showed *an increase of* £32 million, education, including grants to universities, an increase of £25 million, and war pensions, following the recent rise in the rates, an increase of £8 million The Exchequer contributions to the National Insurance Funds were also *a growing and inescapable commitment*, and in the coming year they would demand £100 million, compared with £78 million for last year The increased cost of these items amounted to £87 million, which was more than the whole of this year's increase in Civil Supply This, *Mr Butler said*, was striking evidence that in this field of social services a growing burden on the Exchequer was to be reckoned with Much of the increase in expenditure was *contractual*, while the remainder represented what he was convinced was a worth-while investment in the future well-being of the country Investment in human health, wider opportunity, and increased technical skill, meant something *more than* "*investing in success*" *It meant* the assurance of a happily working and socially responsible democracy But if we were to carry this burden we must not only maintain the increase in the national income but also be constantly watchful that all our existing services are administered *as economically* as possible We must examine with a critical eye all the many additional claims which were constantly being made on the Exchequer for new services, so that the basic social needs of our people came first

Mr J A **SPARKS** asked why, *if the Chancellor had* money to spare, he had not used some of it to improve the National Health Service ? For example, why not *reduce the* dental and optical charges and the prescription charge, and waive the charge for appliances for disabled people altogether *Last year the Government contributed* £9 9 million towards child care, and in 1955–56 they proposed to contribute £9 7 million, a reduction of £200,000 But during the last two or three years the policy had been to reduce the number of day-nurseries throughout the country, squeezing out these children and depriving industry of the labour of able and capable young women, just because they had children Another direction in which the Chancellor might have used some of his surplus was in reducing the interest rate for housing loans or in providing interest-free loans for that purpose

Foot-and-mouth Disease

In the House of Lords on April 20, the **EARL OF LISTOWEL** drew *attention* to the Gowers report which had unanimously stated that in dealing with this disease vaccination was no *alternative* to one *traditional* policy of slaughtering infected animals and contacts He asked the Government accepted the Committee's ations, and in particular what were the Government's views on the use of vaccine during an epidemic, and on the proposal to set up a veterinary research council

In a *maiden speech*, *Lord* **ADRIAN** said that the Gowers Committee, of which he was a member, would have been glad to recommend a different method of controlling this disease, but they were forced to conclude that the slaughter policy for the present was cheaper and safer *than any other* Vaccination had been tried on a large scale and, within limits, had been extremely successful In countries where the disease was endemic the slaughter policy was impossible, *and* there the only possible method of coping with it was by vaccination But vaccination still had considerable limitations No-one claimed that vaccines gave 100 % protection Young animals could not be immunised at all, and in adults the *dose had to be* repeated every six months There was the usual difficulty with virus diseases, that an unexpected strain might turn up which rendered the vaccine prepared from the usual strain ineffective

Britain was fortunate in belonging to the group of countries which had natural barriers against infection Foot-and-mouth disease had never become established in Australia, New Zealand, Canada, the United States, or here We got only occasional infection from the Continent which could be dealt with by the policy of stamping out which was far safer than wholesale vaccination would be But vaccination did raise the resistance to infection and the possibility had been investigated of *using it as an additional safeguard* Some *countries* which, like us, slaughtered infected animals and the contacts, also built a ring of immune cattle around the outside of the infected area But the committee could find no clear evidence that this policy would be effective in the conditions that existed in this country The committee were attracted to the idea that valuable herds of cattle might be preserved by vaccination when an epidemic threatened *from* abroad, but decided that even that limited use of vaccine would be too risky to allow at present If it was certain that vaccination would give 100 % immunity, it would be reasonable to allow prize herds to be protected in this way, but with only 90% *immunity there would be a risk of masked* infection

Vaccination might never be the right method for this country On the other hand, we were threatened every few years by the big epidemics on the Continent, so any improvement in vaccines would be to our advantage *Though we did not use vaccines ourselves*, it was m important that the Government research station Pirbright should go on experimenting with th Pirbright was not only our research centre, it was al an insurance against possible disaster It was con*ceivable that* we might be faced with an epidemic fr the Continent too severe to be controlled by slaugh In such an emergency the Continental countries w themselves need all the vaccines they could manuf and we should have to rely on what we could make h Pirbright would *have to make it* or to supervise production Lord **ADRIAN** knew that steps had be taken to enlarge Pirbright and he hoped that it w be enlarged sufficiently At the moment there was a l in the foot-and-mouth front, we should use it to our defences

EARL ST ALDWYN, joint parliamentary secretary the Ministry of Agriculture, said that the Go accepted the Gowers Committee's recommendation the stamping out policy was right for this country normal *times*, but that vaccination might be valua in an epidemic so serious that slaughter was n practicable nor economic, but the Government took view that an outbreak would have to be except bad—much worse than anything so far—before the of vaccination would be *justified* It would have to left to the Minister to decide whether, and, if so, whe impose vaccination Frankly, the contingency se rather remote He admitted that experts disagreed the possibility that vaccination might mask inf but until we knew for certain that no such danger ex the Government believed that the risks to the far community as a whole would outweigh the benefit individual farmer might gain from vaccination of particular herd

The further expansion of Pirbright Institute wa matter in which the Government felt they ought oceed carefully It might be that no more physical pansion would be needed, provided there was a reserve pacity of output that could be called into use if cessary The Gowers Committee had suggested that might be worth while considering whether a separate eterinary Research Council ought to be created That estion had been raised some time ago with the Privy uncil but it was felt that it would be a retrograde step separate research in animal crop and soil husbandry l of which are the responsibility of the Agricultural esearch Council

The Government also accepted the recommendation hat private collectors of waste food for animals should e licensed and the swill sterilised They were not, owever prepared to extend this requirement to swill ollected by local authorities, since they feared that it ould deter local authorities from collecting kitchen aste separately Kitchen waste would then be dumped ith other refuse where it was impossible to prevent all isk to animals

QUESTION TIME

Dentists' Remuneration

Replying to a question Mr IAIN MACLEOD Minister of Health, said that after a full investigation into earnings and practice expenses the Secretary of State for Scotland and he had agreed with the British Dental Association on an ncrease in the present remuneration of general dental practitioners.[1] A new scale of fees was being worked out and the ecessary regulations would be laid before the House of ommons in due course The new scale would be designed o give dentists a net income comparable having regard to he volume of work done with what they would have received n the period covered by the investigation had the 10% duction not then been in force They had also agreed as an terim measure while the new scale was being worked out o cancel the 10% reduction in the present scale Regulations ith this effect would be laid as soon as possible They timated that the cost of these changes would be about 1 million in a full year

Increased Expenditure on Food

Replying to a question Sir EDWARD BOYLE, economic retary to the Treasury said that of the increase of 16% consumers expenditure on food between 1952 and 1954 arly half—representing a rise of 7%—was an increase in lume and the rest a rise in prices The standard of living the average weekly wage-earner which fell considerably ween 1947 and 1951 had risen considerably since the ter date.

Financial Loss on the Remploy Scheme

Replying to a question Sir WALTER MONCKTON Minister Labour said that the excess of expenditure over income Remploy Limited was estimated for the period ended rch 1 1955 to be £2 430 000

School children and Milk Tablets

Replying to a question Mr D F VOSPER parliamentary retary to the Ministry of Education said that milk tablets re being used in about 800 schools in England and Wales. e Minister approved their use only where the education thority was unable to make satisfactory arrangements for upply of fresh milk. He hoped that fresh milk would rtly be available again in practically all cases. It was the nister s desire that liquid milk at a reasonable price should supplied to all schools and he had no doubt that this estion would come to the notice of the people in the areas cerned The number of schools to which milk could not be pplied on account of their inaccessibility had shown a nsiderable reduction over the last three years and it was ped that that would continue

Mr HASTINGS: Does the Minister realise that milk tablets never take the place of fresh or pasteurised milk and that the preparation of tablets important substances are moved which are not replaced unless special conditions ply? Mr VOSPER: Yes. Milk tablets are really a substi e for reconstituted dried milk to which I think they vide a more palatable alternative but they are no sub tute for liquid milk. The large number of cases have arisen through inaccessibility but because of a dispute which ope is of a temporary nature

In England Now

A Running Commentary by Peripatetic Correspondents

HOPES of a cure for arteriosclerosis have been revived by exciting news from China. Scientists have long been puzzled by the apparent immunity of the Chinese to arteriosclerosis. Therefore, the discovery of a new drug, prepared from the muck weed *Yen Wu Pong* and given the approved name of hydroxypropyl *nor* yen wupongine, is not without interest

The credit for the first thorough investigation must go to workers at Barthomary's Hospital where 7 patients with thickening of the radial arteries were given H N Y W P by continuous intragastric drip for 47 hours. Careful palpation of both radial arteries only three months later showed complete arrest of the disease process in no less than 71% of cases. One patient died of coincidental lymphosarcoma and one took his own discharge In the light of these findings further investigation was deemed reasonable

A large-scale clinical trial was then instituted by the Arteriosclerosis Research Panel, urgently formed by fellows of the Royal Colleges with a personal interest in the problem The panel was commendably cautious in its interpretation of the Barthomary series, since no controls were used and wisely insisted that the trial should include at least 5000 treated and untreated cases. Also, in view of the need for certain special clinical and pathological observations—e.g pulse and sedimentation rate—supplies of H.N Y W.P were restricted to the teaching hospitals. A shortage of clinical material proved an early obstacle and it was found necessary to appeal for suitable cases of essential hypertension, coronary sclerosis cerebral thrombosis, gangrene and senile dementia It is only fitting to record the magnificent and magnanimous response by most non teaching hospitals

Some important facts were brought to light. For instance it was conclusively established that where both cerebral hemispheres had softened as the result of hæmorrhage, the lesion was irreversible and the administration of H N Y W.P could serve no useful purpose No definite conclusions could be reached as to the earlier claims from China and Barthomary's, but it was recommended that provincial hospitals undertake further trials The panel added the interesting observation that a statistically significant number of chronic bronchitics were afforded symptomatic relief during the trial

* * *

The departure of our living in maid for a post in which she is to be paid what is almost my salary before deduction of tax has led me to consider with scientific detachment the problems of running a house I have been appalled by the time which women waste in their homes. The basic fault is psychological and only a change in mental attitude a sort of rearrangement of conditioned responses, is needed to give them a great deal of leisure

After only a few moments concentration I devised for example a rapid method of making beds. Instead of tucking in each sheet and blanket separately all the bed-clothes were straightened en masse by rapid tugs at their lateral edges; even the process of airing was eliminated and no cold damp air substituted for the warmth of the recently occupied bed. My wife received this time-saving manœuvre with the horror of one who is incapable of reasoning from first principles even though my results were shown to be identical with hers.

A further proof of the power of habit and propaganda over intellect is the reverence with which women regard absolute whiteness If advertisements would extol light grey as an ideal of excellence we should save much time particularly in the family wash.

Again, take dust Women regard a light film of dust on furniture as a blemish and spend valuable time in removing it Yet they actually put dust on their own noses. While I should be against an entire reversal of attitude towards noses and furniture I think that a little conditioning would induce women to regard a matt surface on furniture as desirable as a bloom on a peach

Washing up is another branch of household management which needs scrutiny by men. Cups, for example are by custom washed all over whereas only a small section of the and the bottom actually require this attention. Plates which may merely need a dusting are always placed in the washing-up bowl. Incidentally one plate can nearly always be made to do the work of two. Stainless steel sheeting on table tops would at once abolish table cloths and the need for washing them.

By suitable suggestion and propaganda, I believe one might even modify that astonishing feminine reflex, loosely termed "spring cleaning" as though it happened at only one season in the year. My own slogan, NO DIRT—NO COMFORT, has so far yielded little result but one has only to think of that cleanest of all rooms, the operating-theatre, to envisage the antithesis of cosiness. Who could imagine an operating-theatre containing a really comfortable arm-chair, a man smoking a pipe, an open coal fire, and a sleeping dog? Surely it is not beyond the wit of men to fashion a domestic world in which it would be comfortable and restful to live—in fact a world that was not too clean.

* * *

When the tobacco-smoke has cleared a little, could somebody please give thought to the automobile as a biological hazard. I don't mean road-safety, or exhaust fumes. Nothing mechanistic like that. If the anthropo-automobile relationship were given as much attention as, say, fluoridation of public water-supplies we might elucidate coronary thrombosis perhaps, or peptic ulcer. Driving a car does something to the driver as well as to the car. Women have their style of driving. So have teen-agers. Different cars respond differently. Every car has a personality—its *innate characteristics modified* by its environment—which reacts with the personality of the driver. Put a lorry-driver behind the wheel of an MG—would he melt into the mechanism like an undergraduate? There is a biological synthesis in car-driving which we as a profession have ignored. The manufacturers have glimpsed it. "Sparkling performance," they say, implying an individual response to a stimulus. But you've heard the grunts and growls from some of these cars. And what is happening meantime to the owner's systolic pressure or gastric acidity? Couldn't we add to our clinical histories a few notes on the patient's motoring record? Type of car driven, how long, performance, pathology, &c. Just think of the people you know and what happens to them on the road—you'll begin to see meaning in the cold starter, the trouble with the clutch, the heavy consumption of oil. I've talked to the folk at my garage about this. They don't see it. What do they know of engines who only engines know? Besides, the idea really had to strike you before you get it. My car went on fire that summer before the introduction of the N H S. No organic cause was found.

* * *

Our physician has always described the thinning seen in the X rays of some skulls with chronically raised intracranial pressure as "pewtering." He accordingly sent a request to the X-ray department in his usual shaky handwriting: "Skull ?pewtering." But our new radiologist has always used the term "beaten silver." So his report unexpectedly ran—"Two earrings are seen but no pewter ring."

SONNET TO NEGLECTED ORGANS

"Poets have rarely written about the pancreas, lungs or thyroid gland."—I. Davidsohn, M.D., in the *American Journal of Clinical Pathology*, March, 1954.

O Pancreas! I know not what thou art,
Thy islets formed of several kinds of cells
Producing insulin, and something else
Whose name I have forgotten, fill my heart
With wonder, while the lungs to me impart
Their secret motions when the bosom swells,
As seen in those assailed by noisome smells
Or stricken with the wound of Cupid's dart.

But ah, for loveliness that cannot fade
Give me the thyroid, shall I call thee gland?
Within thy vesicles the hormone made
Governs the bulging neck, the trembling hand,
Thou makest lids to lag, and eyes to stare,
patients to discard their underwear.

Letters to the Editor

GENETIC EFFECTS OF THERMONUCLEAR EXPLOSIONS

SIR,—Dr Bourdillon (April 23) is right in thinking that some human mutations could be beneficial but many associated questions come immediately to mind. Are we sure that at its first appearance we would recognise an ultimately beneficial mutation? Are we making full use of those that already occur? Are we satisfied that to get any necessary mutations, it is better to clutter the atmosphere as a whole with radioactivity rather than to expose selected gonads to it? And, finally, have we a satisfactory policy for coping with the defective and monstrous mutations which everyone agrees will greatly outnumber the beneficial ones?

The effects of a given mutation rate clearly depend on the intensity of genetic selection. Under very primitive conditions, with heavy selection, mutation may be advantageous in producing a variety well adapted for life in that particular environment. But, as we get more civilised, the development of sympathy, coöperation, and the medical services goes a long way towards abolishing the selection that originally produced Man. Without selection, mutations are a menace and it is an illusion to think that there is any harmless level of radiation. The random operation of cosmic rays, potassium, radioactive rocks, and other mutagenic agents may well have mediated our early development, but we now exist in spite of them and not because of them. There is little we can do to keep off these agents and ultimately it may be necessary to replace the accidents of natural selection by the methods of the stockbreeder so as to get rid of the accumulated harmful mutants. That is a problem that we can tackle when we are a little clearer about the qualities with which we would endow the ideal human being. Meanwhile, it is surely wise to avoid any conditions that may increase the load of mutations.

Harpenden, Herts. N. W. PIRIE.

PSORIASIS SPONDYLITICA

SIR,—The term "psoriasis spondylitica," used by Dr Fletcher and Dr Rose (April 2) to describe cases in which psoriasis and ankylosing spondylitis co-exist, cannot, in my view, serve any useful purpose, and it appears that the authors themselves were dubious since they quote William of Occam at the head of their paper. To draw attention, however, to this clinical association is of the greatest importance, as I hope to indicate in this short letter. Owing to ever-increasing specialism, syndromes arising from a common pathological stem, now emphasising one and now another feature, according to the specialty of the observer, lead to a multiplicity of descriptive terms which, by their very multiplicity, obscure their *common origin*.

In the field of rheumatoid disease, we know that rheumatoid arthritis, iritis, and psoriasis may occur singly or severally combined. That sex, genetic influences, &c., may modify the point of attack in the tissues should not, however, divert our minds from the essential unity and basic pathological features of all these syndromes and so lead to numerous descriptive terms. It should rather stimulate us to seek an explanation of the differences against a background of a unitary concept.

It is with confidence, therefore, that I now discuss Reiter's syndrome in an attempt to further this unitary approach. Here we find again that rheumatoid arthritis, spondylitis, iritis, and keratodermia blenorrhagica (which is indistinguishable from psoriasis) may all again be severally or singly associated with urethritis in the male. The urethritis, it must be stated, may be as florid as gonorrhœa or may merely consist of threads in the voided urine, with all gradations in between these two extremes.

Knowledge of Reiter's syndrome has, since the war, ablished certain clinical facts which may not however, generally known

(1) It has been clearly established that the systemic com rations of arthritis (rheumatoid type) iritis and kerato rmia blenorrhagica so long attributed to gonorrhoeal infection ve nothing whatever to do with this disease and such ms as gonorrhoeal rheumatism &c should be deleted om the literature Present clinical knowledge shows that ese complications arise from non specific urethritis, and at when they follow a known gonorrhoeal infection a dual fection is present from the outset

(2) Reiter's syndrome may exist either as the complete icture described by Reiter or as formes frustes, where nly some of the features appear Cases are known to occur ither after (*a*) bowel disorders—i.e various dysenteries— r (*b*) sexual exposure

(3) There is no comparable disease in the female associated ith urethritis.

I contend that these facts must be woven into our nowledge of the rheumatoid diseases if we are to get ny clear picture of the various syndromes I would like o mention some other significant facts which go a long ay to explain why tissues so apparently different s joints, eyes and skin should be the seat of attack:

(1) Of all bodily tissues, the joints, skin and eyes contain e highest proportion of hyaluronic acid the substrate hyaluronidase

(2) In the body hyaluronidase is only found under normal nditions in the testes.

(3) Hyaluronidase is secreted by many organisms, especially e streptococcus, which has been traditionally associated ith rheumatoid disease.

(4) The rôle of hyaluronidase is that it facilitates penetra n by an organism of the very tissues affected in rheumatoid ease and the clue to the discovery of the specific organism is in the now well known disease termed non specific rthritis.

Finally reverting to the article by Dr Fletcher and Rose one would expect that case 3 and probably e 2, should show signs of urethral abnormality, at least the presence of threads in the two glass test for the ure of the disease is that which has so often been n in Reiter's syndrome As I have long held that riasis is a manifestation of the rheumatoid group ope that dermatologists will heed the valuable advice en by Dr Fletcher and Dr Rose and search amongst ir abundant material for further cases of this nature.

F L LYDON

ROPHYLACTIC PSYCHIATRY IN CHILDREN'S HOMES

SIR,—The article by Dr Neustatter in your issue of ril 16 is very welcome It is most reasonable to expect at these young psychotic casualties will develop more rmal personalities with such prophylactic measures n they could have done if left in the environment ich gave rise to their difficulties.

In the field of mental deficiency rich rewards await ventive psychiatric treatment I refer to the inaugura n of babies hospitals apart from colonies of adults ldren's and babies hospitals are just as essential for treatment of mentally ill children as they are for treatment of other diseases—and doubly so when child is born with its illness as in mental deficiency bies hospitals could accommodate children from ancy up to five years old

rom intensive therapy in such units for the mentally fective one would expect the following benefits

(1) *Habit training* This, done by experts in the ideal milieu the proper habit training time should lessen the big nursing blem attached to the low grade adult population in the sent-day hospital for the mentally defective

2) *Speech training* Intensive work by the expert speech rapist at the normal speech learning period should cut out much of the inarticulate speech which is such an added handicap to many mental defectives.

(3) *Orthopædic treatment and physiotherapy* could be instituted earlier with better final results; and much spasticity associated with mental deficiency could be relieved by suitable training of the very young child.

(4) *Special training* Observation and assessment by the psychiatric personnel would be able to decide which children could benefit by education in the 3 Rs and which in practical skills, and thus save much time and money in educating unsuitable types.

It may be that such hospitals exist in full therapeutic and research usefulness I understand that there are babies' units attached to large colonies for mental defectives, but I have not read results therefrom Certainly in this area our mentally defective infants material remains in the lap of the mothers one of whom recently told me that she carried her problem from doctor to child welfare centre to hospital to specialist to mental deficiency officer, but always back home again It is probably a matter of money but intensive therapy in a hospital for mentally defective infants might save much by preventing a long stay in hospital later and by making useful material out of what must, under present circumstances be permanently useless

Morpeth, Northumberland

J H. THOMPSON

RUPTURE OF LAPAROTOMY WOUNDS

SIR,—As the pioneer of the use of nylon for suturing the abdominal wall[1] I am very interested to find that others are using it with satisfaction From my own experience of many hundreds of cases sutured with nylon or catgut I have formed fairly definite opinions of the advantages and drawbacks of the former

(1) The use of the thicker sizes (no 5 upwards) increases greatly the risk of discomfort and chronic sinuses in the wound I have used mainly no. 3 myself and the incidence of sinus formation has been very low even in infected cases. At the same time I have removed quantities of the thicker sizes inserted by others. Tissue reaction is known to be greater with multifilament than with monofilament nylon and it would seem that it may be related to the surface area of the material used

(2) The tensile strength of nylon, as served up in the theatre, varies considerably in spite of the maker's claims of uniformity even though it has been sterilised on the one occasion only My theatre staff are also definitely of this opinion We have tried various methods of sterilisation without any noticeable difference I must agree with Dr Greenwood (April 9) that nylon can at times snap with disconcerting ease and it should be well tested immediately before use This criticism applies to multifilament as well as to monofilament nylon.

(3) The monofilament variety is the one which has the advantage over other non-absorbable suture materials of being solid, but it has the drawback that it breaks easily at knots or when sharply angled

Experimental work has indicated that wound healing is quicker and safer with non absorbable sutures than with catgut and my clinical experience supports this conclusion. However the lack of tensile strength in the finer varieties of nylon and the tendency to sinus formation and wound discomfort when thicker varieties are left in situ, have led me to develop a technique whereby the buried sutures can be removed after the tissues are soundly healed. A continuous interlocking chain stitch with no 8 nylon identical with that made by children's sewing machines is inserted with a Reverdin type needle both ends and the terminal loop being brought through the skin The loop is held over a piece of rubber tubing and Finesay buttons are applied to the two free ends After two weeks or more, when the wound is considered strong the rubber tube is slipped out of the loop and the starting end of the suture is cut short after which traction on the other end withdraws the whole suture

---

[1] Haxton H *Brit med J* 1945, i, 12

This method has the advantages of the good support and quick healing associated with non-absorbable sutures, combined with freedom from the spectre of chronic sinus formation The method has been in use for 18 months, in parallel with a series in which 40 day catgut was used, and it works well It has the advantages over through-and-through or figure of eight sutures involving the skin of being much less painful and leaving less ugly scars

I should like to add one comment on the technique, described by Mr Oldham (April 16), of using a doubled suture, cutting the terminal loop, and tying the ends together In this method the terminal loop is of single strand thickness, and a suture, like a chain, has the strength only of its weakest part I agree with him that it is easy, and desirable, when burying suture material to tie the initial and final knots on the peritoneal aspect of the aponeurosis

Manchester HERBERT HAXTON

CARBONIC ANHYDRASE INHIBITION

SIR,—As acetazoleamide ('Diamox') can lower the arterial-blood CO_2 level it would seem to be the ideal diuretic to use in the treatment of emphysema heart failure because respiratory acidosis is common in this condition In your leading article of April 2 you mention the favourable results that have been reported[1 2] in the treatment of emphysema heart failure and respiratory acidosis respectively My experience, though limited, differs from that of the workers you mention

There is no doubt that diamox can cause a diuresis in heart failure of varying cause, but in assessing its value in emphysema heart-failure one must remember that an acute respiratory infection may precipitate cardiac failure in an emphysematous patient and that the œdema clears as the infection subsides Diamox should therefore be tested in those with chronic failure and a "stable" chest Such cases are uncommon I have treated 2 such patients with diamox and compared the diuresis with that resulting from mercurials

Diamox can lower the arterial CO_2 level, and the importance of this in the treatment of acute or chronic respiratory acidosis is at once obvious I have treated 5 emphysematous patients suffering from an acute respiratory infection and complicated by heart-failure and drowsiness, another 2 patients also had CO_2 narcosis as a result of oxygen therapy, and 2 had chronic respiratory acidosis, neither with œdema The case of the acidosis in one of them was continuous oxyg administration

During diamox therapy the diet was either salt free contained 1 g of sodium a day Initially the dosage of di was 8 to 12 mg per kg body weight daily but it was f that 250 mg twice daily was as effective and free from tox effects A single daily dose of 500 mg often caused headache and drowsiness Brachial artery puncture was done on t day before diamox was given, and on the second or third day of therapy two to three hours after the morning dose of the drug

The results are shown in the accompanying table It w be seen that there was a diuresis in those with failure due to acute respiratory infection but not in those with chron failure The 2 patients with chronic failure did howev respond to mercurials and ammonium chloride The ment state improved in only 1 patient—a man admitted becaus a respiratory infection complicated by drowsiness and hea failure Oxygen therapy produced mental confusion and sweating He was given 625 mg of diamox in a single dose in the morning and the oxygen was continued intermittently Aft three days he was fully orientated At this point the arter blood pH was 7 33, the pCO_2 79 mm, the CO_2 content 7 vols %, and the O_2 saturation 87 5% Diamox was th stopped and the arterial blood twenty four hours later show a pH of 7 42, a pCO_2 of 57 mm, a CO_2 content of 60 vols. and an O_2 saturation of 78% Two days later, still with diamox, mental clarity was retained and the blood find were pH 7 35, pCO_2 65 mm, CO_2 content 68 vols. %, O_2 saturation 90% All the samples were taken with patient breathing oxygen In view of these findings I do think that the improvement in the mental state can attributed to diamox

5 patients were adversely affected by the drug is not surprising, for, although the arterial CO_2 was usu reduced, the pCO_2 was not significantly lowered indeed was often raised Nadell[3] reported well of th use of diamox in 3 cases of respiratory acidosis In case she states that the drowsiness, cured by diam returned seven days after the drug had been discontin From the data it is seen that this change was assoc with a fall in pH and a rise in CO_2 and that on resump of the drug the pH rose and the CO_2 and pCO_2 Observations that I have made of similar events occur under similar circumstances in patients not rece diamox lead me to believe that the fluctuations in mental state are related to abrupt changes in the ar saturation rather than to the effects of diamox

Messrs Lederle kindly supplied the diamox used in investigation

RADIOLOGY OF PLACENTA PRÆVIA

Sir,—I agree entirely with Dr Russell and Dr arrick (April 16) regarding the importance of the liological demonstration of anterior placenta prævia only "difference" with them, if such it can be called, in the modesty of their claim for not only is it ssible to infer the site of the low anterior placenta wadays, radiologically but it should be possible in arly every case (after 32 weeks) to estimate the *degree* extension of the placenta on to the lower uterine gment Furthermore with increasing technical pre sion in the radiography of these cases, it becomes creasingly possible to go further and to show *factually* a number of patients (approximately 30%) the acental outline by revealing placental calcification his is a real advance fact in place of radiological pinion in this very important type of case

It should be recognised however that there is another mportant demand for precise localisation of the placenta and I always mention the placental site even if I have ot been asked to do so)—and that is in breech presenta ions, for separation of the anterior placenta *can* occur s a result of manipulation during attempts to perform ersion. Clearly in this case the danger to the fœtal ife-line is great—but the chance of the obstetrician to ave the fœtus may be less than in placenta prævia ases simply because it may be too late to do anything about it by the time recognition of the tragedy has ccurred.

Therefore I wish to join Dr Russell and Dr Warrick n their appreciation of the grand example which Frank Reid has set before the radiologists of this country in this atter of estimating the placental site accurately

St. Mary's Hospitals
Manchester 13.

J Blair Hartley

INTRINSIC FACTOR

Sir,—Mr O'Brien and his colleagues [1] have carried out n excellent piece of work in being the first to isolate an pparently homogeneous intrinsic factor substance from uman sources

I do not however find it surprising that the molecular eight is so different from that of our own material[2] hich was isolated from pig mucosa Using normal and strectomised rats in a study of the absorption of radio tive B_{12} results have been obtained which indicate at "intrinsic factor probably has some degree of ecies specificity These observations are not yet pub hed and have been carried out in collaboration with y colleagues Mr C G Clayton and Dr B Schofield ey have already been briefly reported.[3] Similar observa ons have been made in relation to animal nutrition[4] idence is therefore accumulating which indicates that number of different intrinsic factors occur in Nature state of affairs in some way paralleled by the blood oup substances which are also mucoproteins It is parently quite fortuitous that pig mucosa has proved ective in human patients suffering from pernicious mia

Although I feel these observations are adequate explain the difference in molecular weight it is uch more difficult to draw conclusions about the fference in biological activity It would indeed be rprising if pig intrinsic factor proved to be more active an human intrinsic factor in the human being Whilst agree with the possibility that the human material lated may be an intrinsic factor precursor I think one t seriously consider the likelihood that there has en some degree of biological inactivation Such partial inactivation does not necessarily affect the physico chemical tests for protein homogeneity It is not beyond the realms of possibility that it might have been brought about during the conditions associated with the operation the anæsthetic might be one possible factor

POLIOMYELITIS NEONATORUM

Sir,—Dr Twining McMath (March 26) may be correct in considering paralytic poliomyelitis neonatorum a rare disease He will find in the *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service* for August 1953 a full and interesting review, with 32 references, of Poliomyelitis in Infancy, Especially in the Neonatal Period by Dr J T C. Sims Roberts and Dr D Thomson Their paper includes an account of an outbreak in a private maternity home of 13 lying in beds in which 4 newborn infants were affected developing the illness thirteen twelve ten and eighteen days after birth The first 3 died in six one and two days respectively and the 4th had paralysis of the left arm The diagnosis in each case was confirmed by laboratory findings and type-3 virus appeared to be responsible

EFFECT OF ANÆSTHESIA ON CARDIAC IRREGULARITIES

Sir —We have been investigating the electrocardio graphic changes during induction of anæsthesia, and Dr Barnard's letter of April 16 has encouraged us to give a brief preliminary account of some observations on trichlorethylene

An unselected group of 20 adult patients undergoing E.N.T surgery were premedicated with Omnopon and scopolamine E.C.G recordings were begun in the anæsthetic room and then sodium thiopentone (300–500 mg) was followed by nitrous oxide oxygen and trichlorethylene from a Boyle's machine This was continued for 10 minutes with the trichlorethylene lever at the on position A further dose of 200 mg thio pentone was followed by intubation. The E.C.G results during this period are summarised as follows (3 patients showed more than 1 effect):

Group I (unchanged)	1
Group II (vagal effects)	9
Group III (T-wave changes)	11
Group IV (Q R S-changes)	2

It is with group III that we are concerned here In 8 cases the shape of the T waves changed during anæs thesia suggesting that the pattern *before* induction was abnormal possibly because of apprehension, and became normal after thiopentone and trichlorethylene

No doubt T wave abnormalities are common prior to induction and disappear with anæsthesia but we shall be interested to know if others have observed cardiac disturbances abolished during trichlorethylene administration

Robert I W Ballantine
Ian Jackson
B G Wells

Sir,—I was interested in Dr Barnard's report of a patient with auricular fibrillation whose heart returned to normal rhythm after an anæsthetic technique incor porating trichlorethylene Since beginning to work on the effects of this drug in 1930, I have used it on a large number of patients suffering from thyrotoxicosis with auricular fibrillation for partial thyroidectomy, and in a considerable proportion a normal rhythm returned before the end of the operation, and was often permanent These patients were premedicated either with rectal paraldehyde and hypodermic scopolamine or with pethidine and scopolamine, none was given atropine and few had had digitalis within a week of operation, so that these factors suggested by Dr Barnard can be eliminated The removal of thyroid tissue could also have had no effect at this stage My impression is that *any* type of general anæsthesia except chloroform and cyclopropane tends to abolish auricular fibrillation, although paradoxically it may initiate arrythmias in patients with a normal cardiac rhythm

SANATORIA

SIR,—This correspondence has underlined the wide divergence of opinions held by most sanatorium physicians on the one hand and most chest-clinic consultants on the other In this problem, as in so many others, there is no hard-and-fast yes or-no answer The pattern of the disease itself is changing and hence the methods of management change From the beginning of the century, the cry has constantly been heard that the solution to the tuberculosis problem is within sight It is true that the mortality-rate from the disease has progressively declined, but that decline apparently started even before the discovery of the tubercle bacillus Yet perhaps it is more true today than it was ten years ago that the next ten years may show a considerable change in the epidemiology of the disease, which may well involve a considerable reduction in the number of beds required in the country

That many patients with active pulmonary tuberculosis can be adequately treated at home, has now become accepted as almost axiomatic There are, however, still several reasons for the maintenance of sanatoria which qualify this statement The first one is that domiciliary treatment is only possible where the home surroundings are entirely suitable, and when these conditions do not exist, the patient must be nursed in a sanatorium

Whatever may be the future developments in the epidemic nature of the disease, there is no evidence that our present methods of treatment of pulmonary tuberculosis result in a cure—as "cure" is understood in relation to other infectious diseases such as the pneumococcal and streptococcal infections It is more than likely that the tendency to relapse will persist, and under these circumstances it is still essential that the tuberculous patient should be taught to live with his disease It is this one great and essential quality of education of the patient, in the management of his own affairs and of his own particular tuberculous disease, that of itself justifies the maintenance of sanatoria in any scheme for the management of tuberculosis

The programme of education must include not only instruction from the medical and nursing staff, but also an active assimilation of knowledge by the patient himself, from the precept and example of the staff and the other patients around him And it is clear that this is one important factor which cannot adequately be provided by domiciliary treatment except under exceptional circumstances Whether this period of education be long or short, it is an important part of the treatment of the individual and is obviously best conducted during the early phase of treatment Frequently at this stage many patients are infective, and this may well be an added reason for maintaining such institutions with the purpose of limiting the spread of infection until it is considered that they are of little risk to others

Many sanatoria have become chest surgical centres with large thoracic surgical departments It would be difficult, even if it were considered advisable, to move these to other institutions, and this would also tend towards the maintenance of the sanatorium organisation

One of the major problems in the administration of any [illegible]erculosis scheme is the management of the chronic sputum-positive patient, particularly those who are homeless Many of these are suitable for and agree-able to a hostel type of environment This kind of patient is, however, prone to recurrent periods of relapse requiring hospital treatment, and it may be that the possibility of utilising sanatoria for the provision of both hospital and hostel accommodation for these chronic patients may not be beyond the bounds of administrative possibility

Much has been made of the argument that the chest-clinic physician should follow the progress of his patient and his family throughout the whole period of management of his illness This is a fundamental argument and would seem to be invalidated because of the separation of chest clinic and sanatoria physicians But if the policy of some of the more enlightened authorities is followed, of integrating chest clinic and sanatoria staff, then the separation is eliminated and each physician has the same opportunity of complete follow up of his own patients After all, the principle of having one physician to run an outpatient department only, and another one to be responsible only for the inpatients admitted from that department, has long ceased to function in most other branches of medicine

If, therefore, the chest clinic physician and the sanatorium physician each has his own outpatient and inpatient facilities, then I would suggest that the sanatoria which are required for the tasks which have been outlined may function more effectively and economically in the conduct of those procedur which can most effectively be carried out in sanator alone

Leeds Chest Clinic

GORDON EDWARDS

KWASHIORKOR

SIR,—For some years the English doctors who studying malnutrition among African children h chosen the word kwashiorkor to designate one of diseases they found. According to the recent book Dr Trowell and his colleagues,[1] the term kwashior is used by African tribes to name a disease found children who are weaned early because of a new pregna in the mother since the parents consider that the sec foetus will kill the first child, possibly by poisoning milk of the mother This superstition created the te kwashiorkor to indicate the precarious and unfavo able physical and psychical situation of the child wh deprived early of its mother's breast-milk

Dr Trowell and his colleagues give a new significa to the term kwashiorkor Other interpretations have b and no doubt will be, suggested, but these authors give up to date interpretation and explain that it refers to succession of facts, the most important of which is wean to this they add the overpopulation of the countries as a consequence, a keen competition for food Would tribes that coined the word agree to this social interpreta which has been accepted by other modern scientists? over population existed for as many years as the term been used?

In Mexico the Aztec tribe coined the word "tzipitl" be used for the same purpose Since then, the child falls ill due to the mother's pregnancy, and to a prem weaning, is called "chipil," according to C A Ro *Dictionary of Aztechisms*, and to F Santamaría's Ge *Dictionary of Americanisms* The term is often used to de the child's physical, social, and emotional conflict br about by a new pregnancy of the mother But among d the term has never been used to connote the various n tional states of the child, although a "tzipitl" is usually undernourished child

The words "kwashiorkor" and "tzipitl" cannot be ad for medical nomenclature just to maintain a colourful, e tradition of the tribes that invented them Outside many doctors see in this effort to preserve a strange term o differently interpreted and with so little scientific meaning nly a romantic desire to perpetuate absurd expressions of African tribes, to which Dr Trowell and his co-authors give n interpretation in the light of modern knowledge

---

[1] Trowell, H C, Davis, J N P, Dean, R. F A. Kwash London, 1954

Other countries could surely find terms which would suggest rejudices and superstitions among their own peoples, and which would illustrate signs or accidents of undernutrition ut those words would have nothing to do with true scientific erminology

If nutrition means the normal process of assimilation of he food components and malnutrition is the imperfect ssimilation of these components, we have an adequate nd precise term to name an old disease of humanity which may produce different pathological pictures.

Dr. Trowell and his colleagues find the term malnutrition nsatisfactory because it does not define the type of malnutrition they insist there are many types of mal nutrition, one of which is kwashiorkor Undoubtedly there re different degrees, clinical features and pathological hanges in malnutrition, according to the stage of development of the disease, but it cannot be accepted in the light f modern knowledge that there are many types of mal nutrition. Kwashiorkor or any of the hundreds of names by hich malnutrition is known in Africa in South America, r in Asia, have the same cause—namely a deficiency of he nutrient elements whether through a fault of ingestion igestion, absorption, or assimilation.

Although terminology is important it is of small ignificance compared to the excellent study which r Trowell and his colleagues have carried out in ndernourished African children Their book is of great alue to all who are interested in this particularly urgent roblem of malnutrition We are grateful to the authors r their generous references to the Mexican work on alnutrition

FEDERICO GÓMEZ

RUPTURE OF THE DUODENAL STUMP AFTER GASTRECTOMY

SIR,—In their letter of April 16 Mr Lunn and Mr Noon scribe what is one of the commonest and certainly the st lethal, forms of intestinal obstruction that may low partial gastrectomy of the antecolic Polya type ging from the increasing number being reported in literature the condition is being recognised more ently, but even so it is difficult to diagnose since symptoms are often vague and the obstruction often partial. The particular kind reported by Lunn and n is dangerous since the vascular supply to the ent loop is embarrassed, and I therefore call atten , as I did in my two papers[1,2] on the subject to the l to close the gap between the anastomosis in front the transverse colon behind in order to prevent any he six different patterns of obstruction described in second paper Surgeons use the antecolic rather than retrocolic, reconstruction to save time but now that recognised that the gap in the former should be ed, this time-saving factor disappears since it is er to close the gap in the mesocolon made during the ocolic operation

he second most important point in Lunn and Noon's , though they do not mention it is the disadvantages he long afferent loop In order that the afferent loop herniate through the gap from right to left it must a long one say 12–18 inches though of course if gap had been closed even a long loop would not e herniated.

There are however two other dangers of the long rent loop I have published elsewhere[3] 3 cases, and e since had a 4th in which the long afferent loop r the course of time became concertinaed by adhesions producing such severe afferent-loop symptoms as to require further operation The third disadvantage is that very occasionally a long loop leads to steatorrhœa

THE HAIR OF THE PILONIDAL SINUS

SIR,—Although my own investigations concerning the origin of pilonidal sinuses are already in process of publication elsewhere, I should like to intervene in the controversy between Mr Patey and Professor Scarff (April 9) and Mr Weale (Jan 29 and April 16)

Mr Weale is to be congratulated on drawing attention to a method of establishing the polarity of loose hairs or hair fragments, but his finding, in seven specimens sectioned that the root ends of the hairs were directed cranially does not prove that they grow there Nor does it prove that this is the invariable arrangement I have described hairs entering a sinus tip first while still growing from follicles in the surrounding skin I have even seen a hair bent at its middle into a U-shape the apex of the U bend had entered a sinus, one end was growing from a follicle and the other was lying free externally It follows that Mr Patey and Professor Scarff's barley-corn trick (which works with my hair) cannot be the only force promoting entry Their original suggestion of a suction force which Mr Weale mentions with scorn proves to be correct, for I have demonstrated measured, and recorded it and a manometer tracing is included in my paper

If my theory is correct, hairs growing from the surrounding skin with their tips entering a sinus should be a common sight They are If Mr Weale is right, it ought to be possible to demonstrate hairs growing from undoubted follicles in a squamous epithelium at the cranial end of the sinus. It is not I have been unable to find a single illustration of such an occurrence during an extensive search of the literature

ROGER BREARLEY

PREPARATION FOR WAR

SIR —Dr Glaister (April 16) in his devastating analysis of the emotional basis of power politics compares national (or power bloc) strivings for domination in a world of nuclear weapons to the child's fantasies of making the world conform to his desires rather than make the necessary compromise between those desires and reality It is no longer necessary to quote authorities to show what devastation must follow the use of H bombs, nor to show the inevitability of their use if they are manufactured But people follow their governments in refusing to make these facts the basis of rational thought they pretend that the facts are not there—that it is possible for the Powers to go on preparing to attack each other without ever actually doing so, to make preparations so much more terrible than the other side that it would be possible to 'win' a war and to construct a 'civil defence' which has some genuine reference to H bombs. It is pathetic and terrible to see men and women in positions of authority and trust simply running away from their moral responsibilities deceiving themselves and others into believing that there is such a thing as 'peace through strength' The French decision not to manufacture the bomb could yet be made to create the conditions in which governments might have the courage to tell their peoples that there is no longer safety in having two or three times as many H bombs as your enemy Churchmen to declare the moral degradation of preparing them and the leaders of our profession the futility of pretending that it would be possible to offer medical aid to more than a few of the survivors

Public Health

The Caravan Site

THE control of camping sites has perplexed the public-health authorities for so many years that it is refreshing to see an excursion from the confines of an unrelated specialty to present the point of view of a medical caravanner Whether it would be practicable or expedient to enforce the standards suggested by Mr William Hunter, F R C O G , is another matter He quite rightly points out[1] that many of the nuisances and abuses are due to the indiscriminate subletting of caravans, and he proposes that such hiring should be either prohibited or strictly controlled on selected sites The idea of segregation of the casual visitors from the owner-occupiers is an *apartheid* policy which might work to the mutual happiness of both groups, and indeed already obtains on some sites where the management need to exercise a firm control, or where the cultural outlook of the caravanners produce a natural clique pattern in the lay-out There would seem to be little chance of obtaining statutory powers to limit subletting, and even less chance of being able to enforce them

There is a better case for segregating permanent residential caravan sites from the more nomadic varieties, because a residential site really has the character of an improvised housing-estate and needs more highly organised communal facilities if it is not to degenerate too rapidly into a shanty-town slum Most local authorities look askance at the formation of such settlements, which seem to attract problem families and an endless succession of opportunists who try to use the caravans as springboards to jump the queue for priority in rehousing It is a practical defect in the Housing Act, 1936, that two years must elapse before a particular caravan can be condemned under the slum-clearance procedure It does not necessarily follow that no caravans should be used for permanent habitation They offer valuable scope to the tuberculous and the eccentrics, but for various reasons those people are perhaps better accommodated on individual isolated sites The casual visitors to isolated unlicensed sites remain an insoluble problem, since they drink water at their peril from polluted streams and dispose of their waste to endanger small private water-supplies Their education by an extended Country Code may be the only remedy

Mr Hunter is more concerned with the genuinely mobile caravanner being able to find the decencies of civilisation where he stops for the weekend, and the local residents would share his wish for their own sakes But even the more gregarious nomads vary in their requirements Many scorn the creature comforts of the luxury site to glory in their dream of Romany life and endure for a brief spell the more primitive sanitary habits of the gipsies, leaving unmistakable evidence where their caravans have rested For those who cannot do without the collective security of urban life, the fully equipped site is the answer Mr Hunter favours plenty of room between vans, space for easy version, and waterborne sanitation Refuse disposal can be easily organised, but rural water-supplies are often well below urban standards So long as there are such differing demands there will always be wide variations in sites It takes all sorts both to make a world and to tow a caravan

A well-organised site can, as Mr Hunter says, be a hygienic place which is an asset to the district, and the keynote is proper management by the site operator If the manager is worth his salt there will be no need for the sanitary inspector and the police constable to be hovering by the gate Surely it is better that the site owner should run his own business in an orderly and efficient way than to make bad laws to suit hard cases, and any law that cannot be enforced is bad A convoy of caravans can be driven straight through the law as it stands at present The uncertain interpretation of the Public Health Act, 1936, the status of the exempted organisations, and the anomalies with the planning legislation all make control a dangerous and irritating game of bluff In a recreation so diverse in character it would be very difficult to close all the loopholes Mr Hunter advocates stiffer penalties for breach of conditions attached by a local authority to the site licence, including even revocation of the licence to operate the site Such withdrawal would impose a financial penalty incommensurate with the offence—a principle that is only occasionally and reluctantly applied in English law Caravanners, site operators, and local authorities are only too conscious that we live in an imperfect world, but a code of good caravanning practice may achieve much better results in the long run than all the threats of penal reprisals and the temptations of evasion We seem to be made that way

---

Obituary

ROBERT DAVIES-COLLEY

C.M G , M Chir Camb , F R.C S

Mr Davies-Colley, consulting surgeon to Guy's Hospital, died on April 16 at the age of 73

He came of a well-known medical family His father, J N C Davies-Colley, was also senior surgeon to Guy's; his brother Hugh was civilian surgeon to the Cambridge Military Hospital, Aldershot, and his sister Eleanor, who died in 1934, was the first woman F R C S Robert himself was educated at Westminster School, Emmanuel College, Cambridge, and Guy's After qualifying in 1906 he held house appointments and registrarships at Guy's, later becoming lecturer in surgical pathology and curator of the museum. Meanwhile he obtained the higher surgical qualifications, taking the F R C S in 19 and proceeding to the degree of M.CHIR the following year In 19 he was appointed to the honorary staff, but his work there was soon interrupted by the outbreak of war and during 1914- he served in France and later in Mesopotamia where he was consulting surgeon to the Expeditionary Force with the rank of colonel For this work was appointed C M G in 1918 and mentioned despatches

[Barbara Davies Colley

On his return to civilian practice he took up his consulting practice again, and he also became consulting surgeon to the London County Council But Guy's remained the centre of his work and interest To the hospital, his juniors, and his friends he gave whole-hearted loyalty and in return received whole-hearted affection His chief interest was in surgical pathology which he taught well, and, though he was him little of an innovator, he performed the valuable function of the critic Hating bluff and show, he was one of those that hold fast to what is good A massive figure, with beak of a nose and shaggy eyebrows, he was very part of Guy's Outside his own hospital he was examiner for the Royal College of Surgeons, the University London, and the Society of Apothecaries

N M writes " Davies-Colley—affectionately D G always gave one the impression of a countryman whose lot Fate had cast capriciously in the city, where the fullness of time his gift commanded professional recognition and renown

" He was already a person of note at Guy's when first entered the school some 47 years ago There he initiated me into the mysteries of obstetrics and gynaecology while he was serving his apprenticeship as registrar in that department before proceeding to general surgery Between the two world wars we were colleagues on the senior staff of Guy's, and from the year of crisis 1939 association grew closer as we served together in the E M S at Farnborough, in Kent, where he was the ficient officer in charge of that decentralised unit of our parent hospital. There his lucidity of thought and simple directness of action, qualified by patience and disciplined by strict integrity stood us all in good stead as we strove to coördinate the dual control of central and county authority and reconcile their often divergent views on methods, means, and objectives He was tactful too.

"Much of his success as a surgeon was due to the acuity of his insight and to his refusal to be distracted by irrelevant detail. When his counsel was sought it was with confidence that he would advise no hazardous adventure by Surgery's wilder shores, but direct one along the safest path where lay the greatest promise of relief"

Mr Davies Colley married in 1908 Emily Cecilia daughter of Arthur Crosby-Jones There are two daughters of the marriage.

DAVID THOMAS BARRY

M D R.U.I D.Sc. N U I., F R.C.S. D P H

Professor Barry who died in London on April 15 won professional distinction in two countries In Eire he held the chair of physiology at University College, Cork, and during vacations he joined an active group of experimental physiologists in France This cross-Channel contact was of great value to him as a teacher

He was born at Ballyanihan co Cork, in 1870 and he studied medicine at Queen's College Cork, where he graduated M.B R.U.I in 1894 He spent some years in general practice at Rock Ferry, Cheshire, during which he attended courses at Liverpool University He proceeded to his M D in 1903 and the D P H in 1904 After some years of postgraduate study in London with Starling and later in Berlin and Heidelberg he took his F R.C.S in 1907 The same year he was appointed to the newly created chair of physiology in Cork at Queen's College (later renamed University College) His first task was to build up his new department which had previously been linked with the department of anatomy

During the 1914–18 war he was not released for service and he remained in Cork. In 1918 he took the D.Sc After the war he spent his vacations in France where his wife, the daughter of a Paris architect, had settled with their children Barry worked in Paris at the College de France with Gley, at the Sorbonne with A. and B Chauchard and the Lapiques, at the Institut Marey, and in Dinard at the Laboratoire Maritime In 1920 he was appointed chevalier of the Légion d Honneur

He published some 60 original papers many of which dealt with heart perfusion and electrocardiography He also condensed and translated many papers for *Physiological Abstracts* He retired from his chair in 1942

[Lafayette

A. St G H writes: David Barry was an individualist, whether scientific or social, and one whose words always *provoked thought though not* necessarily agreement. His Irish forthrightness resulted in lucid exposition of the interpretation he had put on the problem discussed whether it was the mode of contraction of the heart, the position of the Church in Science or the support of Science and Medicine in the British Isles as contrasted with the Continent. He felt deeply and sincerely, and sometimes discussion became difficult though never dull.

His studies in Heidelberg Berlin and Paris were in the tradition of the British and Irish scientists and medical men at the turn of the century

Those who examined with him will well remember his home the pleasure of meeting his wife and the sense of culture thought and generous warmth of heart which existed in that old historic home of the Bishops of Cork

Professor Barry is survived by his widow, Marie Yvonne, née Boiret, and by their two sons, Dr C T Barry and Dr D R Barry

Notes and News

THE WEST END HOSPITAL

Many hospitals were heavily damaged during air attacks in the late war, but the West End Hospital for Neurology and Neurosurgery (as it is now called) in London was particularly hard hit In 1940 the outpatient department in Welbeck Street was struck by a bomb and a nurse was killed A fortnight later a land mine fell in the grounds of the inpatient department in Regent's Park Happily there were no casualties, but the building was badly shattered It was repaired, only to suffer even more severely in 1944 when a flying bomb killed eleven patients and one nurse, and a second nurse lost her sight Despite these blows, the hospital's work (like so many other important features of the nation's life) went on. Beds were lent by various other hospitals, and after the war, in 1946, a neurological unit of 60 beds was set up at St Charles's Hospital, Ladbroke Grove, and this is still in action

With the coming of the National Health Service, the future of the hospital was discussed, and it was finally decided that the premises in Dean Street so long occupied by the London Lock Hospital should be reconstructed as new (and now combined) inpatient and outpatient departments of the West End Hospital And the culmination of this plan has now been marked by a reception held in the newly fitted outpatient hall in Dean Street on April 22 Extensive reconstruction has met all the complex needs of a modern neurological hospital, and it was clear to guests at the ceremony that the hospital staff are looking forward to the opportunity of providing, in their new home, an even finer service than at any time in the hospital's distinguished record, which began in 1878

There will be about 40 beds to begin with, but there is room for expansion Wards have been named after the nurses who were killed or gravely injured during the bombing The department of speech therapy which has long been associated with the hospital will carry on its work and so will the School of Speech Therapy Various special departments are attached to the hospital, such as dermatology, orthopædics, ophthalmology, and otorhinolaryngology, so that the neurological consultants will have ready access to colleagues in these specialties But the extensive psychiatric and child guidance departments, which had grown very large (too large, many thought, in relation to the size of the hospital as a whole), will in future work independently as the St Marylebone Hospital for Psychiatry and Child Guidance, in Cosway Street, off Marylebone Road

At the reception Dr T Rowland Hill, physician to the hospital, welcomed as its new patron, Lord Bruntisfield, and he spoke warmly of Lord Bruntisfield's considerable services to the hospital in the past, particularly during adverse times Dr Rowland Hill hoped that the hospital, now that it had recovered from its wartime setbacks, would expand still further in the future Meanwhile, he felt that the new building would give an impetus to even better achievements in neurology and neurosurgery

THE INWARD EYE

Most of us, as the years go by, learn to take new experiences with a certain fortitude But this by no means always applies to æsthetic experiences, and many people are profoundly disturbed by unexpected sounds in music and unexpected methods or subjects in painting and sculpture Art critics have their work cut out to interpret to each succeeding generation the new forms which the musicians and painters are trying to explore

Perhaps it is true that, as Eric Newton said recently in a broadcast,[1] few of us can read a picture as easily as we read a poem we are not visually literate, and cannot hope to be, for whereas we practise talking, reading, and writing—some of us for many hours a day—few of us ever practise painting at all Moreover we, in this generation, are perhaps confronted, with special difficulties, for many artists have given up representing the visible world in a relatively straightforward way, and are instead concerning themselves with abstractions such as emotions and the contents of the unconscious mind Why not ? They have as much right to unconscious minds as other people and at least as much right as psychiatrists to explore them It does mean, however, that we must take a little trouble to follow their symbols just as it took a little trouble to follow the symbols in, say, T S Eliot's *The Waste Land* This at least, is the opinion of George Wingfield Digby, whose new book, *Meaning and Symbol*,[2] interprets the work of three modern artists—Edward Munch, Henry Moore, and Paul Nash—in terms of Jungian psychiatry

Munch, deeply introverted and depressed, painted pictures which have their counterpart (in content if not in skill) in the paintings of many mentally ill patients in hospital. They often reveal an oppressive universe, his own fear of it and the division he found in his own personality Thus his portrait of himself in an almost deserted restaurant shows, towards the back of the room, a pair of waiters—or perhaps one waiter split in two, the halves standing back to back In *The Fight* two figures, one black one white, prepare for conflict, and in *Unwelcome Guests* he has taken up his gun to shoot, through the window, his black and white doppelgängers as they approach his house His emotional perturbation, like that of Edgar Allen Poe, informs all his work but his skill and power as a painter allow him to use it resourcefully, with beauty

Very different in feeling is the work of Henry Moore, whose vast stone forms of women, generous, mindless fertile are part of the mindless fertile earth out of which they seem to grow He finds in natural rocks, weathered and pierced with smooth holes, a poetic expression of life and change, and he gives to his material much more freedom than sculptors have been wont to do, allowing it "to reduce and assimilate the human character of the form into its own material nature" Digby suggests that archetypal themes of death and rebirth, the dismemberment of Osiris and of Dionysus, and many other echoes from mythology are also to be found in his work

Paul Nash, too, was engrossed by Nature—by the seasons, by strange encounters of natural and man made objects, and, like both Eliot and Moore, by the splendour and generosity of fertility Many of his symbols are as direct and unsubtle as fertility itself—the sunflower, bearer of thousands at a generation the serpent whose head is so often shown piercing the sun's disc, the phœnix springing from a cavernous nest, the convolvulus, the mushroom, the sun itself

To appreciate an artist's symbols is to get rid of a good deal of unconscious hostility, for until we can speak his language he is one of these damned foreigners, and the inward reflection "Can't understand what the fellow's getting at," finds outward expression in "Why can t he talk sense?" But once the secret is out, the language learnt, we warm to him, and are free to enjoy his work And really the trouble required is not very great, for as Digby says, "the expression of an artist who can reach down to the fundamental in human is never as complicated as our thinking processes make it appear, it is usually only difficult to his immediate contemporaries"

CENTRAL MIDWIVES BOARD

The following have been appointed as members of the board for the next three years

Appointed by the Minister of Health —Miss G M Godden O.B.E. S R N, S C M matron, Hammersmith Hospital I G Innes M.D. general practitioner Hull G T Milne assistant secretary Ministry of Health J A. Scott O B E M D medical officer of health, London County Council, Miss V R Shand S R.N, S.C.M. M T D supervisor of midwives Lancashire County Council Arnold L Walker C.B E. F R C.S F.R.C O G casualty obstetrical surgeon City of London Maternity Hospital (chairman)

Appointed by the Royal College of Physicians —Alan A Moncrieff C B E M.D F R.C P Nuffield professor of child health, University of London (vice-chairman)

Appointed by the Royal College of Surgeons —A M Claye F.R.C.S. F R C O G, professor of obstetrics and gynæcology, University of Leeds

Appointed by the Royal College of Obstetricians and Gynaecologists —Victor Lack, F R C.P F R C.S F R.C O G, obstetrical and gynæcological surgeon London Hospital

Appointed by the Society of Medical Officers of Health —Miss Jean Mackintosh M.D senior administrative medical officer Birmingham

Appointed by the Royal College of Midwives —Miss E K Hill S R N S C M M T D supervisor of midwives Holland County Council Miss M I Farrer S.R.N S C M M T D, D N (Lond) matron St Mary s Maternity Hospital Croydon Miss E J Merry S R.N S C.M, general superintendent Queen's Institute of District Nursing Miss M Williams, S.R.N, S C.M, M T D matron Queen Charlotte s Hospital

EMPIRE RHEUMATISM COUNCIL

In his report to the annual meeting of the Empire Rheumatism Council in London on April 27 Dr W S C Copeman, the chairman said that the Council s record of achievement in 1953-54 was one of which they could justly be proud Their views on the recognition of rheumatology as a specialty had been put before the Minister of Health who had promised that in the new Ministry circular dealing with senior appointments, rheumatology would be mentioned as a subject in which a senior medical registrar could be employed during his training The Council judged this to be an important advance

In the past year an all-out effort had been made to increase the Council's finances, and Dr Copeman referred to many generous contributions, and particularly to the heartening response to the appeal launched last October at a dinner at the Mansion House which was attended by the Council s president the Duke of Gloucester

The financial report shows an income for 1953-54 of £16 723 (exclusive of legacies) compared with £10 019 in the previous year Medical expenditure on research work totalled £10 151 as against £8128 in 1952-53

IMPERIAL CANCER RESEARCH FUND

The Fund s annual general meeting was held in London on April 28 In the report on its affairs in 1954-55 the treasurer Mr A Dickson Wright records a further considerable increase in the number of subscribers to the Fund Receipts from subscriptions and donations amounted to £22,880 and from investments to £41 507 Legacies totalled £118,542. Dr James Craigie F.R.S director of the central laboratories at Mill Hill summarises the many pieces of research that are going on there He observes that the inter relationships between many aspects of the work are increasing The clinicopathological research unit, directed by Prof Geoffrey Hadfield at 48 Lincoln s Inn Fields, is finding its quarters much too meagre for the sizeable plans it has in mind, and an offer from the Royal College of Surgeons for the use of two nearby sites has been accepted As soon as the College is able to vacate these buildings, the sites will be let to the Fund, with the right to demolish the existing houses and rebuild.

University of London

Mr G B West D.SC lecturer in pharmacology in the University of St. Andrews, has been appointed to the readership in pharmacology at the School of Pharmacy

The following degrees have recently been awarded by the senate :

M.S—D J Robertson.
Ph.D (*in the faculty of medicine*)—T W Glenister M C Lancaster Khagendra Chandra Basu Mallik.

National University of Ireland

The degree of M.D has been awarded to Brendan O Mordha.

Society of Apothecaries of London

At a recent examination for the L.M.S.S.A The following were successful

R. A. Norton F Heyes A D Scott M. E. Khan G K Gregory A. W L Beatson, A G Day K G Mellish Oxley R A Greig A. W Prentice J G Teall, M. A A M Pelosi D Lyen, D Procter

Royal College of Physicians of Edinburgh

Dr Jessie Macgregor Prize for Medical Women (£75)—An award of this prize will be made in July for original work in the science of medicine Such work may be published or unpublished but must not have been published earlier than July 1951 It is open to women who are graduates in medicine of the University of Edinburgh or who have taken the Scottish triple qualification. Applications must reach the convener of trustees at the college 9 Queen Street Edinburgh 2 not later than June 30

Health Centres and General Practice

A debate on the rôle of health centres in the general practice of the future will be held by the Sigerist Society at 3 P.M on Sunday May 8, at 45 Russell Square London W C.1 Dr Hugh Faulkner will explain why he thinks a general development of health centres should benefit both patient and doctor and Dr Stephen Taylor will present his criticisms and his alternative. The meeting is open to non members of the society

Royal College of Surgeons of England

At a meeting of the council on April 21, with Sir Harry Platt the president in the chair honorary fellowships were conferred on Mr William Doolin (Dublin) and Prof Robert Janes (Toronto) The following were elected to the fellowship without examination as medical practitioners of at least 20 years standing Mr R D Langdale Kelham (Roehampton) Mr L S Debenham (Scarborough) Prof J McCunn (Royal Veterinary College) Mrs E L G Hilton (University College Hospital) Prof G J Cunningham was admitted as Sir William Collins professor of human and comparative pathology and conservator of the pathological museum

The Jacksonian prize for 1954 was awarded to Mr Cecil W D Lewis, and a certificate of honourable mention to Dr Oliver C Lloyd The council selected Portal Hypertension as the subject for the Jacksonian prize for 1956 The John Hunter medal and triennial prize was awarded to Stephen L Baker and the Mitchiner medal for 1955 to Colonel W R M. Drew

A diploma of membership was granted to Barbara Y Stockhausen. Diplomas were granted jointly with the Royal College of Physicians to the following :

D C H—Phyllis B Banks Rosalind A Barnes, Yvonne G Beeching Maurice Berger R. J Burns Alison M. Bush Abdul Hamid Ismail Bustani R J Cantwell Shireen H Captain Verne Caradus Marie D Carroll Delsya R. Association of British Pharmaceutical Industry

At the annual dinner held in London on April 20 Sir Russell Brain P.R.C.P., spoke of the medical profession s debt to the pharmaceutical industry—for its research for its day to-day service in providing what is needed for the treatment of patients, and also for the guidance which we all receive as individuals. No industry surely was faced with more complicated problems—problems inherent in the rapid changes taking place in medicine ' You may embark on some important project producing something vitally necessary at the moment and then very quickly it may all be swept away by the appearance of something fresh And in medicine added Sir Russell we are very much aware of the importance of conditions for the pharmaceutical industry in which it can continue to do its good work in promoting research and compete in the export market with any country in the world Mr J F Boucher president of the association said that of a total annual production of about £120 million, no less than £33 million is exported, which is only slightly less than the £37 million spent by the National Health Service Discussions were still going on with the Health Departments on the principles of establishing satisfactory prices for preparations placed by the Cohen Committee in categories 2, 3 and 4 This is a most difficult question and the departments and ourselves are aware that whatever is eventually agreed great care must be taken to see that our export trade and research efforts are not impaired in any way

Medical Association

The gold medal of the association has been awarded to Sir Henry Newland, a past president of the Royal Australasian College of Surgeons

British Association for the Advancement of Science

The Association's annual meeting is to be held this year in Bristol from Aug 31 to Sept 7 under the presidency of Sir Robert Robinson, F.R S Further particulars may be had from the secretary of the association, Burlington House, London, W 1

Psychosomatic Research

The first European Conference on Psychosomatic Research, held at the Maudsley Hospital on April 22–23 was attended by workers from Belgium, Denmark, Finland, France, the Netherlands, Portugal, Spain, Germany, and the United Kingdom A second conference will be held next year in Amsterdam

Poliomyelitis Research Fellowship

On April 14 the National Fund for Poliomyelitis Research announced the establishment of a fellowship, for two years in the first instance with an annual stipend of £1250, at Queen's University, Belfast (*Belfast News-Letter*, April 15, 1955) Dr D S Dane, who is at present medical research officer at the Institute of Medical and Veterinary Research, Adelaide, will be the first holder of the fellowship

World Health Assembly

United Kingdom delegates and advisers to the eighth World Health Assembly, which opens in Mexico City on May 10, will be Sir John Charles, chief medical officer, Ministry of Health, Sir Eric Pridie, chief medical officer, Colonial Office, Mr W H Boucher, Ministry of Health, Mr J F Hunt, Ministry of Health, Dr M T Morgan, Ministry of Transport and Civil Aviation, Mr A E Joll, General Register Office, Mr H T Morgan, H M. Embassy, Mexico City, Dr A A Peat, director of medical services, Trinidad, and Dr J W P Harkness, medical adviser to the development and welfare organisation, West Indies

British Association of Physical Medicine

At the annual dinner held at the Royal College of Surgeons on April 22 Sir John Charles, chief medical officer of the Ministry of Health, said that we were not the first to be troubled by the cost of medical care an illness of Edward I's, in 1307, including materials for embalming, cost the equivalent of £2000 in our money Nor were we the only people to be troubled one could hardly pick up an American journal without seeing a reference to the subject Nobody was in a better position to influence expenditure than the doctor, and none, Sir John thought, had a more important part to play than the specialist in physical medicine Insurance and the making up of wages had done much to remove people's anxiety, but, good though they were, they had an undesirable side-effect in that often, though not always, they reduced the incentive to get back to work An active and dynamic rehabilitation department could set the goal of speedy recovery A new and growing problem was that of securing the recovery of those who formerly would have succumbed to infection in the United States, it was estimated, 24% of all hospital beds are now occupied by patients over 65 years of age, and by 1970 the proportion will be 34% Rehabilitation required both a medical and a social approach, and should be a part of all clinical practice rather than a single specialty But physical medicine was responsible for the occupational and physical therapy which had so large a part in the rehabilitation of many disorders difficult to handle Rehabilitation needed team-work—the modus operandi of modern medicine, and it should be one of the major contributions of physical medicine to the National Health Service "Everyman is a potential claimant for your geriatric skill"

Lord Horder, the president, said that physical medicine was an integral part of medicine dealing with far more than residues and replacements in industry The association now had 171 members, but numbers did not mean much, and one sometimes learnt more by weighing people s heads than by counting them He wanted the association to be responsible for criteria in physical medicine if anyone was to give the Ministry or colleges guidance on what should be the qualifications for consultant status in physical medicine it should be the British Association of Physical Medicine

Sir William Gilliatt responded to the toast of The Guests proposed by Dr Hugh Burt

OSTEOPOROSIS*

A. M. COOKE
D.M. Oxfd F.R.C.P
PHYSICIAN TO THE RADCLIFFE INFIRMARY OXFORD

(concluded from p 882)

The growth of normal bone and its maintenance in health in the adult depend on a number of factors—genetic, nutritional endocrine, and mechanical. I can do no more than merely mention some of these, but propose to deal in more detail with those relevant to the problem of osteoporosis.

Nutritional Defects

Nutritional defects by which the patient does not receive or absorb adequate amounts of the substances from which bone is made, or adequate amounts of the vitamins concerned in bone formation are important—and in some parts of the world common—causes of medical bone diseases Defects of alimentation include protein deficiency from starvation (Eliot and Jackson 1933) or the protein loss of nephrotic renal disease (Emerson and Beckman 1945) and pregnancy in undernourished women, all of which may result in deficient matrix formation—i.e., osteoporosis

Pregnancy even in healthy women makes considerable demands on the mother for all body constituents, notably protein, calcium and phosphorus Kesson Morris and McCutcheon (1943) compared the incidence of osteoporosis in elderly nulliparous and multiparous women 40% of those who had not borne children showed osteoporosis against 72% of those who had borne many children, and this difference was found to be statistically significant. Nordin and Roper (1955) have recently reported four cases of severe spinal osteoporosis in young women after pregnancy They regard the high level of corticosteroids in pregnancy as a possible factor but it is only right to point out that there are also high levels of œstrogen in pregnancy Those authors do not give details of the patients diets or plasma protein levels

With regard to calcium and phosphorus, Owen Irving nd Lyall (1940) in Aberdeen studied the intake of calcium 16 men aged about 70 in relation to senile osteoporosis or economic reasons the daily calcium intake ranged om 225 to 576 mg Of these 16 patients, 6 had demon trable osteoporosis. Calcium balances showed that the bjects were more or less in equilibrium on an intake of 00-300 mg daily but when given larger amounts 00-900 mg., they retained large amounts of calcium

Vinther Paulsen (1953) in Copenhagen studied 33 tients over the age of 68 (28 women and 5 men) and und that in patients with a daily calcium intake of nder 500 mg the incidence of senile osteoporosis was % whereas in those taking over 500 mg daily it was nly 14% There were similar figures for the phosphorus take His series however, was small and it may be hat the low calcium and phosphorus intakes were part a more general dietary deficiency Except in the osser deficiencies of protein and mineral intake or sorption it is doubtful if malnutrition is a common ent in the production of osteoporosis. On the other nd lack of calcium or phosphorus and/or lack of tamin D will produce osteomalacia—i e deficient lcification of matrix causing the wide osteoid seams stologically characteristic of this disease (Maxwell, Hu d Turnbull 1932, Albright Burnett Parson elfenstein and Roos 1946)

Lack of vitamin C produces the peculiar and characteristic lesions of scurvy, which include defective matrix formation and hence one variety of osteoporosis Lack of vitamin A is not concerned in the production of osteoporosis

Endocrine Factors

At least six endocrine glands influence bone growth in one way or another—namely the ovary testis para thyroid thyroid, adrenal and pituitary

As the actions of the *sex hormones* have been brought to light over the past sixty years, unexpected effects on non-sexual target organs, including the skeleton, have been discovered In 1916 Laurence and Riddle in the U S.A. found that the level of plasma phosphorus in cocks, non laying hens, and laying hens was in the ratio of 100 to 115 to 205 that is to say a laying hen shows double the plasma phosphorus content of a cock, and nearly twice as much as her non laying sister

Riddle and Reinhart (1926) investigated the serum calcium of birds and found in male doves and pigeons a constant figure of 9 0 mg per 100 ml In the female bird with resting ovaries the figure was 9 3 mg , but during ovulation it rose to the remarkable level of 19 9 mg per 100 ml Other species were investigated and it soon became apparent that the large changes in serum calcium and phosphorus were confined to birds and related to the fact that they lay eggs with calcified shells. It was next shown that, before the egg-shell is formed a huge store of calcium is laid down in the bird s long bones In fact the marrow cavity is almost obliterated by bone a process known as hyperossification (Riddle Rauch and Smith 1944) The demand for calcium while the egg-shell is being formed is astonishing—5 grammes may be transferred from the bones to the shell gland in half a day These changes are caused only by the female sex hormones and the male sex hormones have no such effects (Riddle 1942) Also, the hyperossification occurs in para thyroidectomised and hypophysectomised animals just as it does in the normal, so the effects are due solely to the œstrogens (Riddle and McDonald 1945)

Experiments with mammals showed that extended œstrogen treatment was followed by hyperossification as in birds involving an enormous increase in trabecular bone and extensive obliteration of the marrow cavities (Gardner and Pfeiffer 1938 Poumeau Delille and Fabiani 1944, Baker and Leek 1946)

The effects of œstrogens on the skeleton vary however both at different sites and in different species (Sutro and Pomerantz 1942) In mice hyperossification of the long bones is accompanied by dissolution of the pubic bones In the human being and the dove the action of œstrogens is augmented by androgens, whereas in mice the male hormone counteracts the action of the female hormone In the rat, the male sex hormone is the stimulator of bone growth and the female hormone the inhibitor I mention these facts as a reminder of the danger of general ising from the particular and from one species to another (Gardner and Pfeiffer 1943)

In man long-continued administration of œstrogens causes hyperossification as is shown by the case of a patient of 88 years who should have been osteoporotic by reason of her age But she had taken a large dose of dienœstrol (up to 6 mg daily) for over four years for the carcinoma of the breast that eventually killed her Her vertebræ were noticed by the pathologist to be even harder than those of a normal young subject and sections showed besides areas of carcinomatous infiltration areas of cancellous bone entirely free from carcinoma cells where the trabeculæ were much thicker than normal

In man the male sex hormone has the important anabolic action of causing nitrogen retention—because it stimulates the laying-down of protein in muscle and in bone matrix (Kenyon, Knowlton and Sandiford 1944)

Abridged from the Lumleian lectures for 1955 delivered before the Royal College of Physicians of London on April 19 and 21 under the title of Some Aspects of Skeletal Disease amples of lack of the sex hormones, cases have recorded of defective bone growth and osteoporosis inary gonadal insufficiency in both sexes (Albright, Smith, and Fraser 1942, Labhart and Courvoisier 1950)

Of the other endocrine glands, the action of the *parathyroid* on the bones has been extensively studied Hyperparathyroid bone disease results, inter alia, in increased osteoclastic activity, and erosion of bone with cyst formation, osteitis fibrosa generalisata It is possible to have hyperparathyroidism without noticeable bone disease, and these patients sometimes show osteoporosis of the usual spinal distribution as the earliest skeletal involvement

The effects of *thyroid* function on bone are obscure Long continued overactivity of the gland produces osteoporosis Clinical hyperthyroidism and the administration of thyroid extract to normal animals cause an increased calcium excretion (Aub, Bauer, Heath, and Ropes 1929, Albright, Bauer, and Aub 1931), but some authors believe that a diet sufficient to compensate for the increased metabolism prevents these occurrences (Smith and McLean 1938, Drill 1941) Conversely, myxœdematous patients have a diminished calcium excretion

Normal *adrenal* function is also necessary for normal bone growth The condition most studied in this respect has been Cushing's disease, where osteoporosis is common (53 out of 61 cases in the series of Eisenhardt and Thompson 1938) It is interesting to note that an old name for this disease was osteoporotic obesity, and Mooser in 1921 described and illustrated an undoubted case of Cushing's disease under the title of osteoporosis, eleven years before Cushing's description Albright, in his masterly Harvey lecture of 1942 on Cushing's syndrome, attributed these effects to the anti-anabolic action of one of the adrenal cortical hormones, thereby correctly predicting one of the chief actions of cortisone some seven years before its isolation The osteoporosis of Cushing's syndrome differs in some respects from the commoner types in that the ribs are often, and the skull sometimes, affected (Sussman and Copleman 1942) The osteogenic actions of the sex hormones are effective treatment for adrenal osteoporosis (Albright, Parson, and Bloomberg 1941), although of course the other serious features of hyperadrenalism require treatment as well

Lastly, *pituitary* hormones affect the skeleton—for example the defective bone development of pituitary dwarfs, and the characteristic overgrowth of bone in gigantism and acromegaly Acromegaly also causes osteoporosis, probably because of the hypogonadism consequent on the pituitary disease

Mechanical Factors

Of *mechanical factors, immobilisation* of the patient plays the chief part in the production of osteoporosis Indeed, immobilisation of part of the patient will produce corresponding local osteoporosis Our orthopædic colleagues are well aware of the local osteoporosis in the region of fractures, in the limbs of patients immobilised for the treatment of tuberculous joints (Sissons 1952), and in the legs of congenitally paraplegic children (Katz 1953)

It has long been known that injury of any kind is followed by increased urinary excretion of nitrogen, and the nitrogen sulphur and nitrogen-phosphorus ratios suggest muscle protein as the source (Cuthbertson 1930, 1942) Howard, Parson, Stein, Eisenberg, and Reidt (1944) found that after injury the nitrogen loss was maximal at six days, and that the patients reached nitrogen equilibrium in thirty-five days They also noted that the loss of nitrogen was greater in patients with fractures than in others with comparably severe non-osseous injuries In 6 patients the average loss was [illegible] of nitrogen, equivalent to seven kilogrammes of muscle protoplasm High protein feeding had no appreciable sparing effect on the nitrogen loss (Howard, Winternitz, Parson, Bigham, and Eisenberg 1944) As nitrogen katabolism wears off, the protein metabolism returns to normal

The nitrogen loss is paralleled by a calcium loss. Howard, Parson, and Bigham (1945) found that after fractures or operations for osteotomy, patients immobilised in plaster showed an increase in urinary calcium for months, irrespective of a high or low calcium intake The loss remained constantly high, at two and a half times the normal figure, for two months, after which it fell If the patient was allowed out of plaster and mobilised, the urinary excretion of calcium rapidly fell to normal Likewise patients with paralytic poliomyelitis have been known to lose as much as 1000 mg of calcium daily in the urine These high losses in injuries and paralysis are almost unaffected by diet, calciferol, or alkalis

At first, the negative nitrogen balance was thought to be a direct result of the injury, but there is evidence that the immobilisation itself is an important factor (Cuthbertson 1929) Deitrick, Whedon, and Shorr (1948) immobilised four healthy young men in bed with both legs in plaster of paris for six to eight weeks There was of course no injury, but the nitrogen excretion rose, and during the experimental period they lost 30–80 g of nitrogen, which is equivalent to 1–2 5 kg of muscle These subjects also showed about double the normal loss of calcium and phosphorus There were no changes in the plasma-phosphorus or plasma proteins, but the serum-calcium rose by 1 mg per 100 ml

The conclusions from these observations must be that the absence of normal stresses and strains removes some of the stimulus to bone formation by osteoblasts, while normal resorption by osteoclasts continues unchecked

To an otherwise healthy adult the immediate dangers are few restoration to normal activity is followed by retention of calcium and nitrogen, and anatomical recovery But in old subjects and children the picture is otherwise In the former there is likely to be some degree of senile osteoporosis before the injury or immobilisation, and indeed osteoporotic subjects are more liable to fractures than those not so affected Recovery in the aged, whether from incised wounds, muscle atrophy, or bone atrophy, is slower than in the young

In children, the skeletal effects of immobilisation are greater than in adults, and the metabolic upset may even be fatal The change from the normal physical activity of a child to complete rest is proportionately and absolutely greater than in the average adult Cases have been reported by Albright, Burnett, Cope, and Parson (1941), Dodd, Graubarth, and Rapoport (1950), and Halvorsen (1954)

In old patients, another condition where immobilisation may do serious harm, or even kill the patient, is extensive Paget's disease Here, for some unknown reason, bone destruction and bone formation proceed simultaneously in a patchy distribution The bone formation is mostly in the weight-bearing part of the skeleton, the spine and the legs—stimulated, no doubt, by the stresses and strains of physical activity If the patient is for any reason immobilised, bone formation is checked but resorption continues unabated These patients may have hypercalcæmia, renal damage, and what Albright has described as "chemical death" (Reifenstein and Albright 1944)

Stevenson (1952) studied 85 orthopædic patients who had been immobilised for periods varying from three months to two years, and no patient failed to show osteoporosis of all the lower limb bones Sometimes the effects of immobilisation are permanent In children, interference with epiphyseal growth may result in epiphyseal disruption and premature fusion with the diaphysis (Gill 1944) Such patients may also develop a chest deformity sustain fractures from the most minor trauma when they are mobile and develop coxa valga

Attempts have been made to determine how much exercise is required to prevent these osteoporotic troubles It seems to be surprisingly small Deitrick (1948) placed voluntarily immobilised subjects on an oscillating bed for eight to twenty hours daily The oscillation halved the calcium loss and diminished the nitrogen loss and it was deemed to do this by causing a little weight bearing on the heels by inducing slight muscular contraction and by lessening venous stagnation Deitrick found that up to ten days complete immobilisation caused no detectable physical or metabolic damage to the body but that after two or three weeks effects were manifest and might have serious results Wyse and Pattee (1954) found the tilting bed ineffective in paraplegic patients and from their extensive observations concluded that the stresses and strains necessary for the maintenance of normal bone may well be due to muscular contractions rather than mere posture

Some Landmarks

The history of spinal osteoporosis can be briefly told and for practical purposes begins with the studies of Schmorl of Dresden (Beadle 1931) who examined some 7000 spines and described clearly the pathological anatomy Previous writers had certainly described osteoporosis, but had often confused it with osteomalacia and other conditions where the bones are soft or brittle Plummer Dunlap, and Moore recorded (thyrotoxic) osteoporosis in 1928 Between 1930 and 1940 cases were reported in Germany France Denmark, and the United States of America In Great Britain a short communication was made to the Association of Physicians by Morris Kesson and Balfour in 1943 and a full paper by Burrows and Graham appeared in 1945 All these writers found the ætiology puzzling the commonest views being that age and nutritional deficiency were the chief factors

An important landmark was the paper in 1940 by Albright, Bloomberg and Smith who reported 42 cases (40 women and 2 men) aged 65 and under They remarked that no case occurred before the menopause and that several were in women whose ovaries had been removed earlier in life. They therefore inferred that what was then called idiopathic osteoporosis as opposed to senile osteoporosis was really postmenopausal osteoporosis Aware of the high serum-calcium and hyperossification that occurred in female pigeons and doves and the stimulating effects of œstrogens on bone formation in male birds, they tried œstrogen therapy on their patients This produced strongly positive calcium and phosphorus balances maximal in twenty days and continuing unabated for the ninety eight days that the treatment was given On withdrawing œstrogens there was no change for fifteen days and then a slow reversal to the findings before medication A second course of treatment again produced positive calcium and phosphorus balances. Albright and his colleagues were doubtful whether this treatment would prove to be of practical clinical value but in further papers showed that œstrogen treatment was in fact extremely effective in relieving the patient s symptoms and after a long interval in improving the X ray appearance of the bones (Albright 1947a) The first papers on œstrogen therapy published in this country were those of Scowen (1948) and Anderson (1950)

The last landmark that I would like to mention is the addition of male sex hormones to treatment It had been known for many years that testosterone had an anabolic action, produced retention of nitrogen sodium potassium phosphorus, and chloride and promoted an increase in weight and increase in muscle (Kenyon Knowlton Sandiford Koch and Lotwin 1940) It was also found to produce an increase in bone matrix and hence to be a valuable aid in the treatment of osteoporosis (Koc ially 1946, Weinmann 1950) Œstrogens and androg effective in counteracting bone atrophy from disu hal well as from hormonal deficiency (Armstrong Knowlton and Gouze 1945 Gillespie 1954)

The relationship between osteoporosis and the hormones secreted by the male and female sex glands is complicated by the presence of hormones with similar actions secreted by the adrenal cortex It is at present impossible to say what relative parts these two groups play in the metabolism of bone It has been suggested that not only do women undergo a menopause, but both sexes undergo an 'adrenopause,' and men even a 'leydigpause' (Albright 1947b)

Symptoms and Signs

The symptoms of osteoporosis vary from none at all to complete incapacity from severe pains The pains are of many types, mainly in the back radiating around the trunk radiating to the buttocks and down the legs. They are usually aggravated by movement, jarring or flexing the trunk Sometimes the pains are made worse by coughing sneezing or straining at stool suggesting a root origin but, in spite of the skeletal deformities compression of the spinal cord does not occur

The physical signs likewise vary—from none at all to gross spinal deformity The commonest finding is a shortening of the trunk giving rise to a rounded kyphosis and a transverse fold of skin across the upper abdomen (fig 5) The infolded skin is keratinised showing that the fold is of long standing and not a temporary postural phenomenon (Dent, Milne Roussak and Steiner 1953)

The X ray appearances of osteoporosis are important In advanced cases it is difficult to obtain good X ray films, because of the poor contrast between the bones and the soft tissues There is sometimes poorly defined bone texture—the so-called ground glass appearance—and sometimes there is a fainter but coarser trabecular pattern (fig 6) The longitudinal trabeculæ are more prominent than the transverse presumably because the

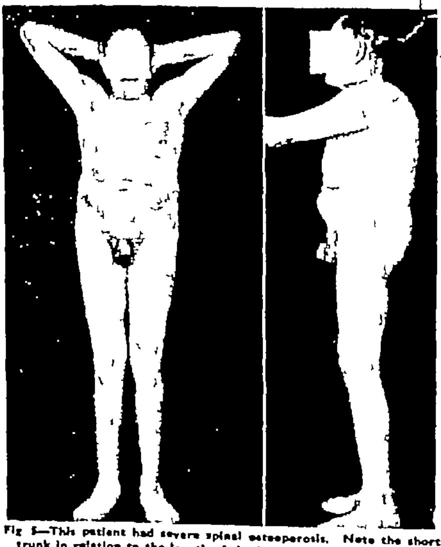

Fig 5—This patient had severe spinal osteoporosis. Note the short trunk in relation to the length of the legs the short neck rounded kyphosis, and transverse fold across the skin of the upper abdomen.

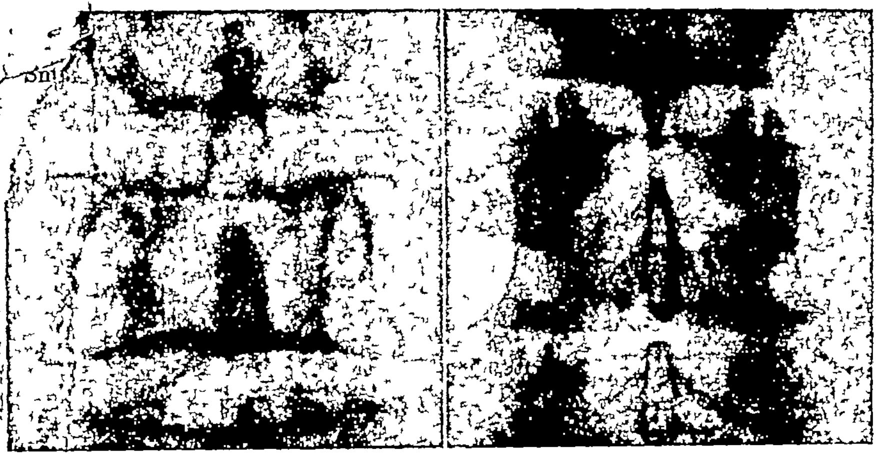

Fig 6—The normal vertebra on the right shows a fine honeycomb pattern, in contrast to the osteoporotic vertebra on the left which is less radio-opaque, and shows relatively few but coarser trabeculæ of mainly longitudinal distribution

stresses are greater up and down the spine rather than across The centra become biconcave, with increase in size in the intervertebral discs (fig 7) The centra may show denser end-plates than normal The condition is most marked in the spine, especially in the lumbar vertebræ There is a general deformity of the column, which shows a rounded kyphosis A kyphosis may, however, be due solely to disc degeneration There may be a wedge-shaped deformity of individual vertebræ All degrees of collapse occur sometimes the spinous processes become so close together that they develop false joints between them (Other decalcifying diseases, especially osteomalacia, produce similar X ray appearances in the spine, so it is unwise to make the diagnosis of osteoporosis on this one observation alone) It is usually stated that in osteoporosis the pelvis may be slightly affected, but the long bones scarcely ever and the skull almost never Actually, the other bones are affected, but less obviously so

Ghormley, Sutherland, and Pollock (1937) found that of pathological fractures arising from non-malignant conditions, one-third were due to senile osteoporosis, a cause three times as common as the next most numerous group

In patients over the age of 50 admitted to the Radcliffe Infirmary for fractured neck of femur, the condition is three times as common in women as in men It is difficult to believe that the women are submitted to more trauma than the men, and one must conclude that their bones are more brittle This belief is supported by work of Rutishauser and Dufour (1950) who examined patients who had died with fracture of the neck of the femur They cut sections of the necks of the unbroken femurs and found that these always showed characteristic changes including osteoporosis The condition is also found in the arms and legs, if the necessary predisposing factors are present and if it is sought (fig 8) These age changes also occur in compact bone as well as in cancellous bone (Amprino and Bairati 1936)

It must be admitted that the difficulties of determining the degree of osteoporosis by X ray examination are great Cobb (in Cowdry 1952) has described post-mortem chemical analyses of phalanges from patients whose hands had been radiographed during life A just-detectable X-ray difference of the dissected bone corresponded to a chemical difference of 9%, but a just detectable difference in X-ray films of the whole finger corresponded with a 25% difference in chemical analysis must be emphasised that these figures were obtained the most easily X-rayed bone in the body and in a uation where there is more bone than soft tissue Decal- spine must be even harder to detect

Similar experiments have been made by Fusi (1953) He placed complete and sliced lumbar vertebræ in 5% nitric acid, which slowly removed the mineral matter Radiological changes were visible when the isolated vertebræ had lost 3% of their calcium content, but he estimated that in the living subject changes begin to be recognisable only when the vertebræ have lost 60% of their calcium This is a surprising figure, but supporting evidence is provided by some experiments of Ardran (1951) He bored holes vertically through the centra of normal lumbar vertebræ taken from the post-mortem room A hole 3 mm in diameter could be seen clearly in a lateral X ray film of the isolated vertebra, but if the hole was filled with water it was entirely invisible A similar hole 14 mm in diameter—i e , about the size of the spinal canal—and occupying about one third of the diameter of the centrum, was naturally very obvious in an X ray film, but when it was filled with water it was only just visible as a faintly porotic area If this is so in excised vertebræ, no doubt such X-ray appearances would be even more difficult to detect in a vertebra in the body

One may therefore conclude that if there are X ray changes indicating osteoporosis, and particularly if there is vertebral collapse, there must be gross anatomical changes

The Strength of Bone

The mechanical strength of compact bone has been extensively studied, and a remarkable material it is. Its tensile strength is nearly as great as that of cast iron and its crushing strength three quarters of that of wrought iron (Bell, Cuthbertson, and Orr 1941) It is about three times as strong as wood The tensile and compressive strengths of compact bone are about equal, an unusual distinction among building materials

A vertebral centrum consists essentially of a block of cancellous bone, with a very thin outer shell of compact bone and usually weakened by a surprisingly large hole on the posterior aspect for the emissary veins

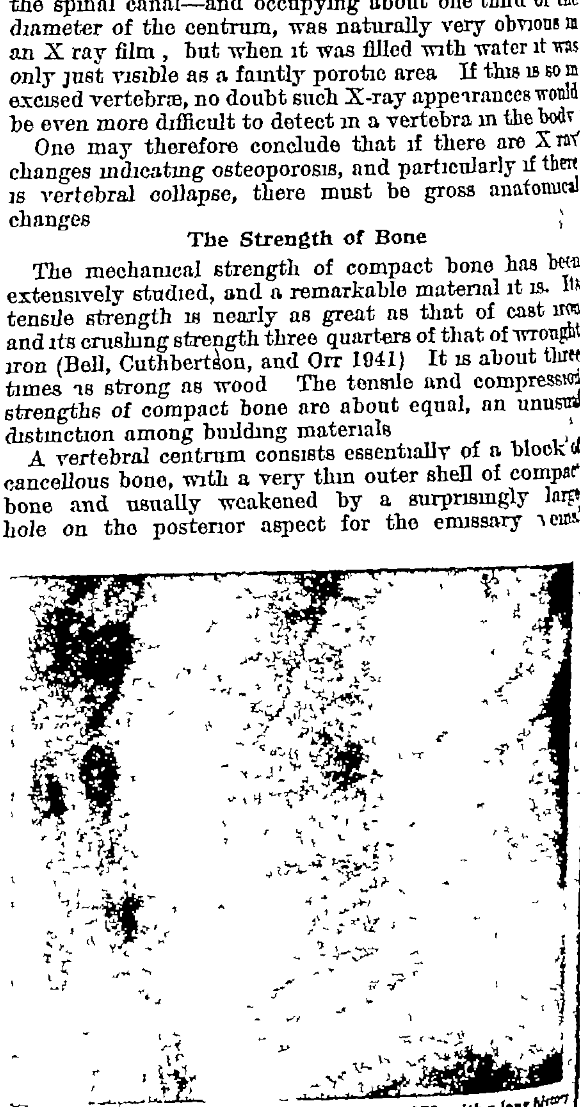

Fig 7—X ray of the thoracic spine of a woman of 73, with a long history of thyrotoxicosis and immobilisation She has a pronounced kyphosis with flattened biconcave porotic vertebræ

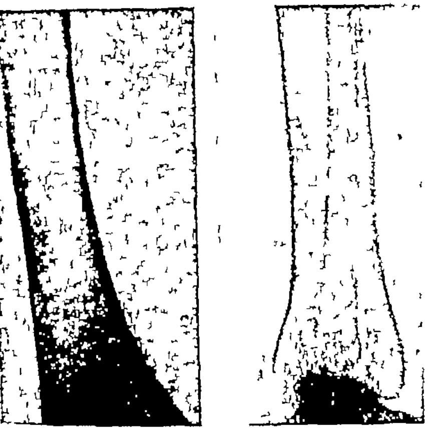

ig. 8 (same patient as fig 7)—X rays of (a) the lower end of the femur and (b) the lower end of the tibia.

have been able to find no modern reference to experi
ents on the strength of cancellous bone Indeed, the
ly publication is that of Ward in 1838 to whose book
have already referred He wrote:

> "A cubical inch of cancellous tissue was cut from the
> entre of the external condyle of an adult macerated femur
> nd subjected to gradually increasing pressure with the
> llowing results It sustained four hundredweight without
> isible alteration; sank a little on one side upon the addition
> the next half hundredweight and continued to yield upon
> ery further increase of pressure so that when the weight
> mounted to 6 cwt., its height was reduced to half an inch
> his reduction however took place entirely at the expense of
> e upper portion of the cube; its lower moiety which

> arison may assist the reader in forming a just estimate of the
> rength of the reticular tissue"

I have performed some similar
xperiments with the assistance
f Dr J D Todd of the School
f Engineering at Oxford which
equipped with appliances for
sting the strength of materials
riefly we found that lumbar
entra from healthy subjects
ithstood a pressure of 0 61–
67 ton (1360–1050 lb) before
ollapsing. The area of a
entrum is about 2 2 sq in
hich gives a strength of about
00 900 lb per sq in as against
he 500 lb found by Ward.
he difference was that his
pecimen was an isolated cube
f cancellous bone whereas ours
ere whole centra which have
thin layer of compact bone
around the outside and are presumably designed specially to withstand the kind of pressure that we applied

As well as the strength of 900 lb per sq in normal centra show surprising resilience even after fracture by compression When the centrum has collapsed, if pressure be increased, the deformity becomes greater until the bone is perhaps only $^1/_4$ in thick and squashed outwards till its diameter is $2^1/_2$–3 in As soon as the pressure is released, the centrum resumes its normal shape and is sufficiently strong to resist deformity by manual pressure

Osteoporotic vertebræ are easily crushed, sometimes by trauma and sometimes spontaneously or at least by the application of little more force than the weight of the upper part of the patient's body or the slight stresses caused by the muscular movements of an old person. Centra from old or osteoporotic subjects withstand a pressure of 300 lb per sq in or less, which may seem a large figure in comparison with the normal In real life, fractures in bones are seldom produced by static forces but usually by relatively small forces applied dynamically Work by Evans Lissner and Pedersen (1948) has shown that a force of only 16 inch pounds, applied dynamically to the femur can produce deformation patterns similar to those of forces of 400–700 pounds applied statically Many forms of athletics and games must produce great stresses on the skeleton but in them fractures are relatively rare because in controlled movements the muscles are used to support the skeleton. On the other hand an unexpected fall on to the outstretched hand may produce a Colles fracture with surprisingly little violence Similarly patients with osteoporosis may fracture several vertebræ from minor but sudden trauma

Diagnosis

As I have said before osteoporosis is, strictly speaking a histological diagnosis and can be made with certainty only by the morbid histologist but there are clinical features and X ray changes sufficiently well defined to justify the diagnosis at the bedside and it is an important diagnosis, because the condition is often treatable (fig 9)

In a patient over 60 years of age any pains in the trunk or legs for which there is no obvious explanation should raise in the physician's mind the possibility of osteoporosis. If the patient is a woman the chances of this being the cause are six times greater than if he is a man If there is a history of loss of height the odds in favour of the diagnosis are further increased In women special inquiry should be made about the menstrual history, the date of the menopause, and any gynæcological operations especially to ascertain whether the ovaries have been removed Questions about diet and physical activity may provide suggestive information

On examination loss of height as shown by measurement evidence of shortening of the axial skeleton a rounded kyphosis, a transverse infolding of the skin

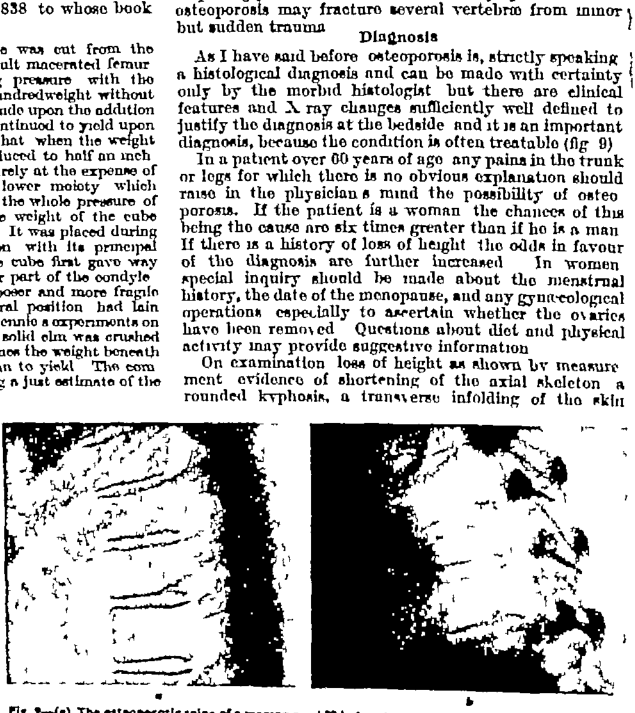

Fig 9—(a) The osteoporotic spine of a woman aged 52 before treatment. (b) The same area from the same patient (then aged 58) after 6 years treatment with calcium and vitamin D This has had no effect on the osteoporosis which has progressed and caused compression fractures

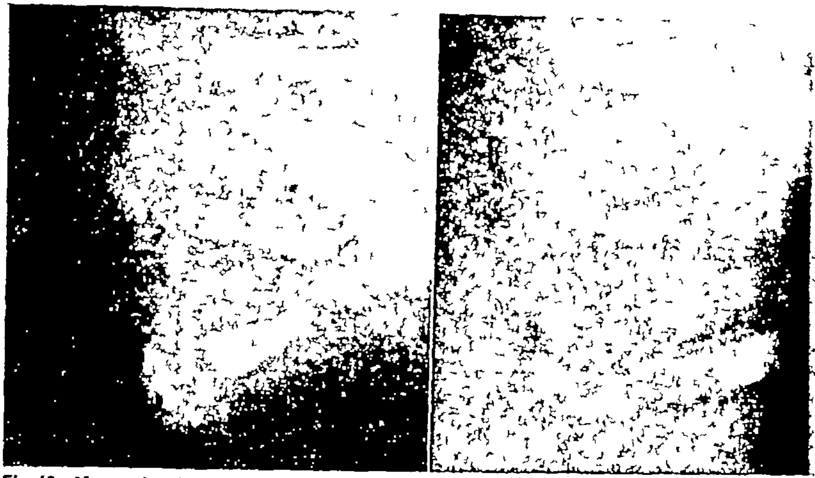

Fig 10—X rays showing radiographic improvement in osteoporosis after 2½ years hormonal therapy

across the upper abdomen, and approximation of the lowest ribs to the pelvis are important signs The patient tends to look older than her stated age, with a lax wrinkled skin Evidence of other disease will be lacking, although the thoracic deformities make the patients unduly liable to chest infections The urine should, of course, be tested for Bence Jones protein, which strongly suggests myelomatosis but is occasionally found in other generalised bone diseases Sulkowitch's reagent for the quantitative estimation of calcium in the urine provides a rough screening test for the excessive calciuria of hyperparathyroidism Radiography of the spine and pelvis will usually reveal the characteristic changes of osteoporosis, with or without fractures If there is doubt, an X ray film of the skull (which is never affected) and some of the long bones (which are rarely affected except in very advanced cases) should provide valuable negative evidence The presence of a pseudo-fracture at once raises the question of osteomalacia, in this country usually a sequel to steatorrhœa

In osteoporosis the serum calcium and phosphorus and alkaline phosphatase are within normal limits The average total plasma-proteins are in the lower normal range and the average plasma-albumin just below the lower limit of normal Basically, the diagnosis is made by the exclusion of other bone diseases Bone biopsy from the iliac crest or from the dorsal spine of a lumbar vertebra is a practicable investigation (Vogt 1949, Vogt and Tonsager 1949) Lastly, it is sometimes justifiable to try a therapeutic test

Diagnostic traps are to be found in the other diseases that produce osteoporosis as a secondary effect Cushing's disease, acromegaly, and thyrotoxicosis usually present characteristic features which should not give rise to serious difficulties More subtle and deceptive are the osteoporotic changes of myeloma, hyperparathyroidism, the osteolytic type of Paget's disease, and so called idiopathic osteoporosis The last is a rare and puzzling variety of osteoporosis occurring in young subjects of either sex, without demonstrable endocrine defect and unresponsive to hormonal treatment

Treatment

The diagnosis of senile or postmenopausal osteoporosis made, the essentials of treatment are firstly to get the patient out of bed, if only to sit up in a chair, at the earliest possible moment Secondly, if the pains are severe, a light spinal jacket will give physical and moral support Thirdly, a high protein diet and a pint of milk a day will ensure an adequate supply of the materials from which bone is formed Last, but not least, is the hormonal treatment Opinion differs on the details, but there can be no doubt that the patient needs some preparation of male sex hormone, such as testosterone propionate 10–20 mg daily by injection, or methyl testosterone 30 mg daily by mouth Androstenediol is said to have the anabolic actions without undue masculinising effect The patient also needs a female sex hormone, such as œstradiol benzoate or dipropionate 2 mg daily by injection, or an oral preparation such as dienœstrol 1 mg daily, or æthinylœstradiol 0 1 mg daily There are satisfactory proprietary preparations containing appropriate mixtures of male and female sex hormones Large doses are not required, and osteoporosis is one [illegible] diseases where twice the dose of medicine does not produce twice as good an effect, but the reverse Indeed, large doses of œstrogens inhibit bone growth Intermittent treatment will tend to prevent unpleasant side effects, and a régime of four weeks' treatment and two weeks off is often recommended Treatment should be continued for a long period, probably for not less than two years In successful cases, the trunk pains will be greatly improved in two weeks, and in severe bedridden cases in two months The effects of treatment are usually more pronounced in patients who have undergone surgical removal of the ovaries than in those who have had the normal gradual diminution of œstrogen action by age

There are many cases on record of patients with postmenopausal osteoporosis, and indeed with senile osteoporosis, who have shown great subjective improvement on endocrine therapy and a corresponding improvement in function, but very few cases have been reported where the X-ray appearances of the bone have been improved Nearly all writers on the subject comment on this curious fact

Cases of X ray improvement have been reported by Albright and Reifenstein (1948), by Sherman (19 by Snapper (1952), and by Polishuk and Kleinba (1952), and I have seen two myself (fig 10) A possible explanation is that X-ray changes for the better are seldom seen before two years' treatment and many patients are not followed up for so long a period Reifenstein and Albright (1947) estimated that osteoporotic patients receiving appropriate endocrine therapy retain about 200 mg of calcium daily If we assume that a severe osteoporotic patient has lost half the bone substance of his skeleton, which is not an excessive estimate, at this rate of replacement it would take seven or eight years to restore the bones to normal

Voltaire's gibe that "a physician is one who pours drugs of which he knows little into a body of which he knows less" is unfortunately still true and applies even to endocrinology In the treatment of osteoporosis, the chief unpleasant side effects arise from the masculinising effects of androgen therapy, which are of course most noticeable in women, who provide the majority of the patients There may be coarsening of the skin, acne, hirsutism, deepening of the voice, and occasionally unseemly increase in libido Oedema of the ankles may occur from retention of electrolytes These effects are seldom serious, but they are distressing to the patient They can best be prevented firstly by the use of small doses, secondly by intermittent treatment, and thirdly by the opposing action of œstrogens

The commonest undesired effect of œstrogen therapy is uterine bleeding in women past the menopause. Th possible carcinogenic effects of male and female sex hormones are a very remote danger because the doses are small and the drugs are merely replacing something which the patient is lacking

Prevalence

How common is osteoporosis? Omitting local forms such as osteoporosis of the pubic bone in prostatic disease Sudeck's atrophy osteoporosis cranii circumscripta, and the like over 800 cases have been reported (references in bibliography marked with an asterisk) The proportion of female to male patients was 6 to 1 and this is a significant ratio to which I shall refer later Albright has described osteoporosis as the commonest bone disease likely to be encountered by the physician Priority of place must I think, be disputed by Paget's disease but there can be no doubt that both are extremely common. It is interesting therefore to see how osteoporosis is dealt with in the standard British textbooks of medicine for students The following table shows the number of lines devoted to the subject in ten such textbooks

Textbook	*Date*	*Osteoporosis of any type*	*Postmenopausal osteoporosis*
A	1950	0	0
B	1950	4	0
C	1951	6	6
D	1952	0	0
E	1952	0	0
F	1953	4	4
G	1953	0	0
H	1953	0	0
I	1953	40	0
J	1954	8	0
	Total	62	10

A Personal Series

My own experience is similar to that of all those who have interested themselves in this condition The adult inpatient records of the Radcliffe Infirmary over the past fifteen years show that, of the common medical osteopathies there have been 110 patients with Paget's ease, 36 with spinal osteoporosis of one sort or another nd 6 with osteomalacia (all from steatorrhœa) I have so found some osteoporotic subjects among the out ttients, and with some private patients have brought e total to 50

Of these 50 patients, 43 were women and 7 men 30 ere over the age of 65, and the osteoporosis was presumbly senile in origin 20 were under 65 14 women and men, and in the women the condition was presumably ostmenopausal (fig 11)

The results of routine laboratory investigations were

	Number of observations	*Mean*
rum-calcium	37	9 5 mg per 100 ml
lasma-phosphorus	32	4 0 mg per 100 ml.
lasma phosphatase	31	9 6 units
lasma-protein	10	6 7 g per 100 ml.
lasma-albumin	10	3 7 g per 100 ml
lood sedimentation rate	26	25 mm. in 1 hour

t will be seen that the serum-calcium plasma phosphorus, nd plasma phosphatase are all within normal limits—a iagnostic point of importance The total plasma roteins are within the normal range but the plasma lbumin is just below the generally accepted lower limit f normal (4 0 g per 100 ml) The slightly raised blood dimentation rate is difficult to relate to the bone ondition because there are so many other factors which ay affect it

Apropos of the low serum-albumin levels Henneman arter, Forbes and Dempsey (1953) tried the effect of rotein administration on 4 patients with osteoporosis. here was no demonstrable effect from oral administraion Daily intravenous injections of 50 g of human rum albumin for periods of from nine to thirty days roduced a rise in serum albumin and considerable etention of calcium and phosphorus Henneman et al aferred, but could not prove that the treatment was a stimulus to bone formation and that serum albumin might 'actually be the transport form of bone matrix precursor'

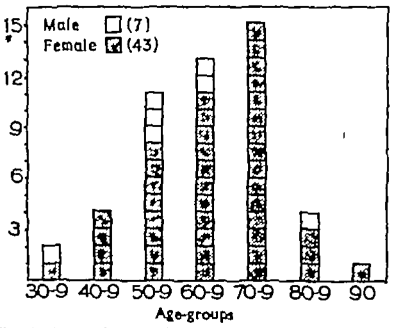

Fig. 11—Age-incidence of 50 patients with spinal osteoporosis.

Of my series 37 patients were given hormones—mostly combined œstrogen and androgen therapy—but 5 had œstrogens only and 3 androgens only The follow up was adequate in 27 cases. Of these, 1 patient said that she felt worse but the remainder reported subjective improvement in varying degrees 4 patients were able to discard plaster casts, and 2, from being completely bedridden were able to get up from bed and walk about 16 patients over the age of 65 were treated with endocrine therapy and adequately followed up Of these 15 were obviously greatly improved and 1 was the patient mentioned above who felt worse

Prevention

There is no doubt that age is a common and important factor but not as has often been supposed, the only factor It is probable that a large proportion of persons over the age of 70 have some degree of osteoporosis The fact that at all ages the ratio of women to men is six to one suggests that something other than age is operative and all the evidence points to this being an endocrine factor

It is a matter of some therapeutic importance that patients with so-called senile osteoporosis respond to the appropriate treatment for so-called postmenopausal osteoporosis. The distinction between these two types is probably not only artificial but non-existent and they are really the same disease

As regards prevention there are about 7 million postmenopausal women in England and Wales, not to mention those younger who have had the ovaries removed or irradiated and over 5 million men above the age of 50 Many persons over 50 will not of course, develop osteoporosis other than the gradual and inevitable changes which will occur if they live till 70 or over But a considerable number will sustain compression fractures of the spine either spontaneously through extreme osteoporosis or through injuries occurring on top of moderate osteoporosis and some will become bedridden and crippled A number will sustain fractures of the femoral neck from trivial injuries

This formidable problem will be met if physicians surgeons and gynæcologists have an awareness of the existence of osteoporosis and its implications and realise that it is one of the few treatable chronic conditions in elderly patients and indeed is probably the only age change in the body that can be reversed

No-one could seriously advocate universal endocrine substitution therapy after the age of 50 It would be administratively impossible and very costly and would carry hazards There are however some simple preven tive measures worth considering, specially by those responsible for the care of old people It will obviously be wise to encourage some physical activity, or at least to discourage undue inactivity It should not be difficult to arrange an adequate protein, calcium, and phosphorus intake—a pint of milk daily would guarantee 680 mg of calcium It would be simple to record the height of each subject annually, and to inspect the abdomen for the appearance of a transverse fold across the epigastrium Any aches or pains in the trunk for no good reason should at once call for antero posterior and lateral X rays

Patients with osteoporosis, or even patients potentially osteoporotic, should be given cortisone or corticotrophin with great caution, if possible not in large doses or for long periods (Hjorth and Dragsted 1953) In the recorded cases of osteoporosis with fractures occurring during cortisone treatment, the patient has almost always already qualified for osteoporosis by immobilisation or the postmenopausal state (Boland and Headley 1950, Teicher and Nelson 1952, Demartini, Grokoest, and Ragan 1952, Curtiss, Clark, and Herndon 1954)

Summary

I conclude by summarising the points which I consider the real essentials of these lectures

Firstly, the skeleton undergoes slow, steady resorption from all its surfaces, more apparent in cancellous than compact bone

Secondly, this process is counteracted by endocrine factors and the physical stresses and strains of use It is affected to a lesser extent by diet and age

Thirdly, osteoporosis is an extremely common condition

Fourthly, so called senile osteoporosis has an endocrine component which is treatable

It will have been obvious that these lectures have been largely a compilation from the work of others, whose original contributions to the subject I gratefully acknowledge I have received the most generous help from colleagues and friends too numerous to mention, but I must allow myself the pleasure of placing on record my particular indebtedness to Dr Alastair Robb Smith

HIATUS HERNIA

SURGICAL RELIEF OF REFLUX ŒSOPHAGITIS

CHARLES WELLS
M.B Lpool F.R C S
PROFESSOR OF SURGERY UNIVERSITY OF LIVERPOOL

J H. JOHNSTON
M.B Belf F R C.S F.R.C.S.I
SENIOR SURGICAL REGISTRAR, LIVERPOOL ROYAL INFIRMARY

HIATUS hernia of the sliding type is a very common condition in which the tissues at the œsophageal hiatus of the diaphragm have relaxed and allow the cardio œsophageal junction to become retracted into the chest This retraction unfolds the acute angle between the œsophagus and the fundus of the stomach which normally prevents reflux of the gastric contents into the œsophagus (fig 1*a*) The hernial sac may occasionally be quite large but usually it is very small—indeed scarcely more than a potential sac which can be invaginated with the finger for an inch or so (fig 1*b*) The characteristic symptoms are caused by reflux and their severity does not depend on the size of the hernia

Ætiology

The ætiology is not fully understood, but advancing years obesity and increased intra abdominal pressure as in pregnancy all play a part Since the pressure within the abdomen is positive and the pressure in the chest negative it is perhaps not surprising that this hernia should appear from time to time, and its more frequent recognition in recent years may be related to dietetic and weight changes in the population Gall-stones are often found in association with hiatus hernia and may arise from common causes Hyperchlorhydria with duodenal ulceration is also a common concomitant and it is possible that in both cholelithiasis and ulcer a vagal reflex may cause muscular contractions of the œsophagus and so lead to retraction of the cardia More probably, however in duodenal ulcer it is the hyperchlorhydria which aggravates the effects of associated but unrelated reflux

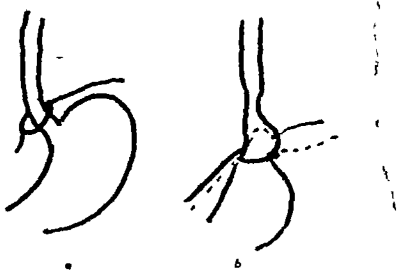

Fig 1—*a* Normal angle between œsophagus and stomach tends to *obstruct gastro-œsophageal reflux*; *b* *retraction* of cardia into thorax is followed by small sac of peritoneum (unfolding of cardia facilitates gastro-œsophageal reflux)

Symptoms and Diagnosis

The symptoms which suggest retracted cardia are heartburn (retrosternal burning pain) and acid regurgitation into the throat especially on lying down or on stooping Later there may be painful dysphagia from œsophagitis or ulceration or obstructive dysphagia from spasm or stricture The stricture may be annular from the healing of superficial lesions or may be due to dense fibrosis of the œsophagus and peri œsophageal structures causing organic fixed shortening Secondary anæmia from steady slight bleeding is not uncommon, and sharp hæmorrhage may rarely occur One of our patients had a fatal hæmorrhage from perforation into the aorta, and in another who recovered, a peri œsophageal abscess was caused by a penetrating ulcer These severe complications are quite unusual and are more likely to arise from ulceration at the level of *the hiatus* in the *gastric* pouch of a large hernia than from the commoner inflammation or ulceration of the œsophagus itself caused by reflux. The pain of a penetrating ulcer is experienced at the level of the lower ribs, especially *towards* the back. It may be excited by swallowing

Investigations to confirm and assess the condition comprise radiography a search for occult blood, the estimation of gastric acidity the *exclusion of* other disorders (e.g duodenal ulcer and gall-stones) and œsophagoscopy The endoscopy may reveal superficial ulceration spasm or stricture formation, redness and œdema or simply an abnormal *regurgitation* of gastric

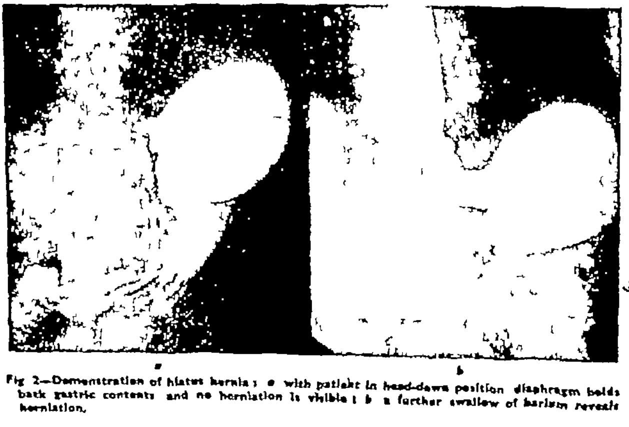

Fig 2—Demonstration of hiatus hernia; *a* with patient in head-down position diaphragm holds back gastric contents and no herniation is visible; *b* a further swallow of barium *reveals* herniation.

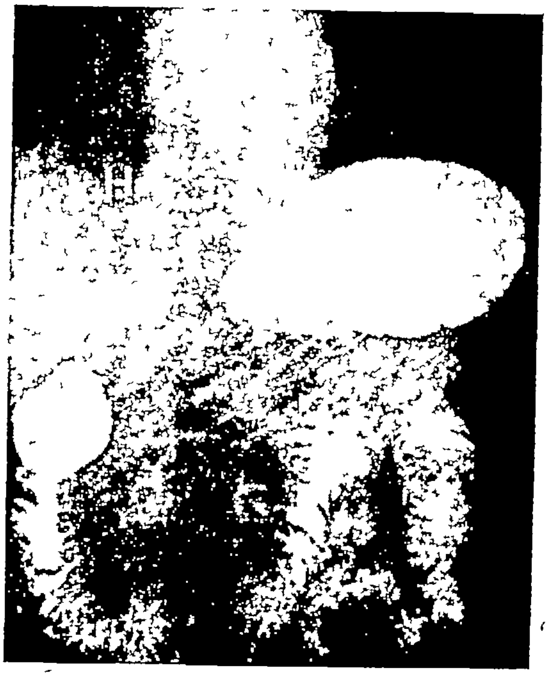

Fig 3—Typical small hiatus hernia.

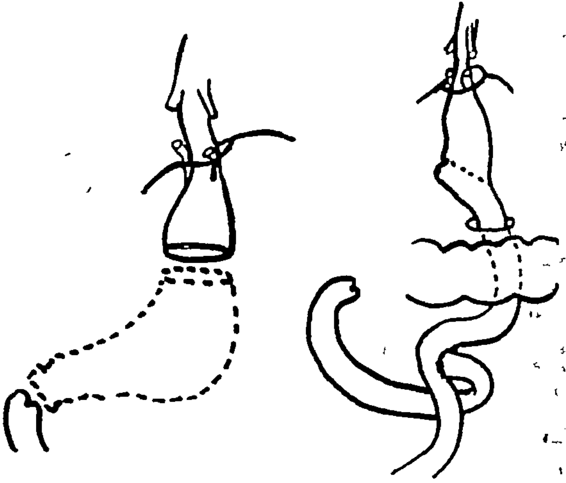

Fig 4—Scheme of operation described in text.

contents Gastric mucosa is seen sooner than is normal in some cases but not in all, since the instrument will displace the cardia downwards in the early and fully mobile case

A normal bismuth series may show retraction and incompetence of the cardia, or this may be demonstrable only with a special technique in which, after the meal, the patient, having been put in the head down position to show the fundus, is given a further bolus to swallow (fig 2) Even with the greatest care it may be difficult to distinguish with certainty between a small hiatus hernia (fig 3) and the physiological intermittent dilatation of the œsophagus, known as an epiphrenic ampulla, which is not associated with regurgitation Observation under the X-ray screen is of the greatest value and most instructive

Treatment

Non operative treatment gives a variable amount of relief Weight should be reduced, and food should not be taken for some hours before retiring, when antacids should be given as a nightcap The patient should be instructed to sleep propped well up with several pillows

Surgical Treatment — Conventional surgical treatment for those who do not get relief from non-operative measures is ordinarily directed to correction of the deformity By a thoracic approach the lower end of the œsophagus is drawn down to below the diaphragm and fixed there with sutures Reconstitution of the normal œsophago gastric angle is the essential and effective step Unfortunately most workers report a high incidence of recurrence after this operation, and in our own hands the recurrence rate has been so high that we no longer use this method

An alternative operation which we practise and advocate is based on a different principle We accept the incompetent cardia but seek to prevent regurgitation by securing rapid emptying of the stomach We also produce achlorhydria and divert the bile and pancreatic stream so that such regurgitation as may persist does no harm These desiderata are achieved by vagotomy, partial gastrectomy, and re anastomosis by the Roux method (fig 4) The approach is from the abdomen

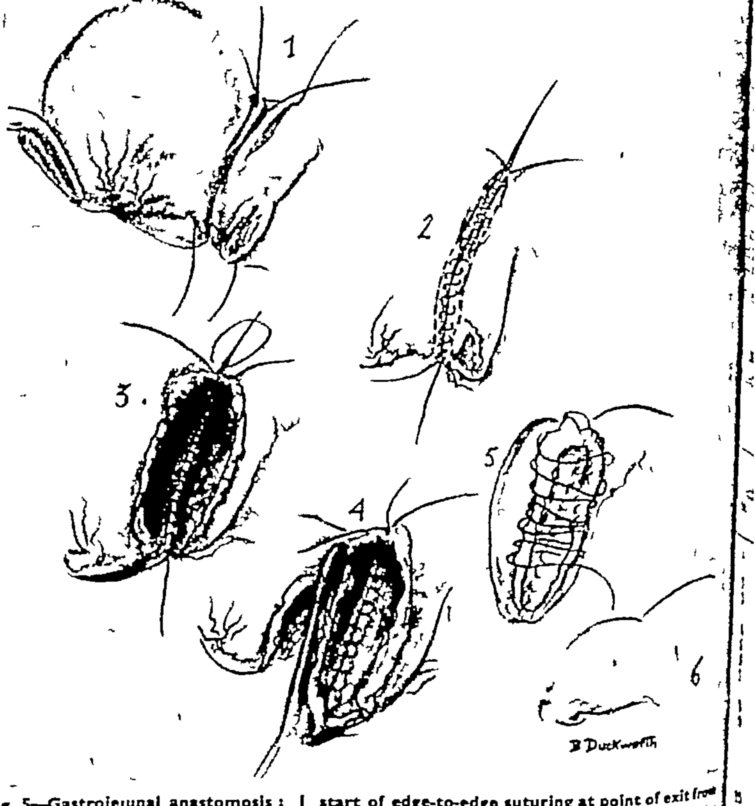

Fig 5—Gastrojejunal anastomosis : 1 start of edge-to-edge suturing at point of exit from stoma near greater curve 2 continuation of this suture line as conventional seromuscular suture and indication, by interrupted lines, of incisions into stomach and jejunum 3 posterior suture line completed and corner at open end of jejunum trimmed away; 4 distal part of stomach being cut away , 5 anterior suture line taking mucosa alone near greater curve and all coats elsewhere (cf fig 6) 6 suture-line completed

und consequently enables any associated abnormality o be given appropriate attention

The diagnosis is confirmed by palpation of the hiatus, hrough which a pouch of peritoneum can be palpated or expelled by the examining finger If the hernia can still be educed which is usual, the left lobe of the liver is mobilised he peritoneum incised around the hiatus, and the oesophagus freed and drawn down into the abdomen for an inch or two Vagotomy is then carried out in the usual way If a completely satisfactory denervation is not achieved this fact should be carefully noted, so that in the event of pain recurring a transthoracic vagotomy may be advised If the patient is obese or if the oesophagus cannot be pulled down, vagotomy by the transthoracic approach becomes obligatory

The gastrectomy follows the usual lines. We like to conserve the gastro-epiploic arch. In hiatus hernia we do not always divide the left gastric vessel near its origin; alternatively we divide the descending branch on the lesser curve About two-thirds of the stomach is removed, and the duodenum is carefully closed as usual.

The upper jejunum is then displayed and a point is selected a few inches beyond the flexure for its division Nutrient vessels are sacrificed and arcades preserved in such a way that the jejunum distal to the cut can be drawn up through the mesocolon and anastomosed to the stump of the stomach without tension The opening at the cut end of the jejunum is extended by an incision along its antimesenteric border and the resultant corners are trimmed away The anastomosis is made with great care at the point of exit at the greater curve since easy emptying of the stomach remnant is essential to success. Sometimes at this point in the anastomosis we use the edge-to-edge technique illustrated in fig 6 The mesocolon is finally fixed to the stomach proximal to and around the stoma.

The anastomosis in Y is completed about twelve inches below the stoma by bringing the biliary loop underneath and round to the left side of the vertical limb To avoid any narrowing of the jejunum carrying the food-stream (the vertical limb) the suturing is done with meticulous care in a special manner As illustrated (fig 6) the seromuscular coats are joined edge to edge with a continuous catgut stitch the loops of which are placed as delicately and as close together as possible The posterior mucosal layer is oversewn, and the stitches almost encroach on the first layer The anterior mucosal layer is made with a Connell stitch almost encroaching on the cut seromuscular coats, and these are finally sutured together as in the first layer This close suturing controls haemorrhage whilst the use of the extreme edges of the structures avoids constriction in a remarkable way

During the anastomosis it is impossible to control bleeding from the jejunal ends with the ordinary bowel clamps, but we have found that Crile's vessel-clamps on the mesenteries are excellent.

Discussion

It is twenty years since one of us performed his first gastrectomy for hiatus hernia. There was a large fixed hernia with a penetrating ulcer of the stomach at the level of the hiatus Polya gastrectomy below the level of the ulcer (Wells 1933) was undertaken as a first-stage procedure It gave complete relief and no further treatment was required More recently however, we have been disappointed with the results of both the Polya gastrectomy and the Steinberg (1940) modification in the presence of retracted cardia because of the persistent

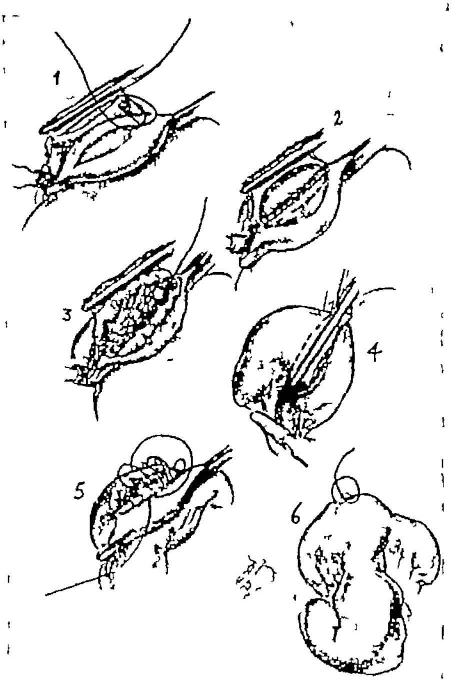

Fig 6—End-to-side jejunal anastomosis by edge-to-edge technique; 1 seromuscular coats joined; 2, incision through mucosa indicated; 3 posterior mucosal layer completed; 4 final seromuscular incision at end of afferent loop indicated; 5 anterior mucosal closure with Connell's stitch; 6 edge-to-edge seromuscular suture completed.

HIATUS HERNIA FORMER OPERATIONS, ASSOCIATED DISORDERS, AND PRESENT SYMPTOMS

Patient no.	Sex	Age (yr)	Former operations	Associated abdominal disorders	Duration of follow up (mos)	Present symptoms	Weight

12	F	61	Cholecystectomy 1940	None	[illegible]	Eupeptic	Unchanged

vomiting of bile In patients 9 and 10, who had each undergone Steinberg gastrectomy, the symptoms of œsophagitis persisted, and there was profuse regurgitation of bile on recumbency or stooping Conversion of the anastomosis to the Roux type, without disturbing the original gastrojejunal stoma, and vagotomy, have produced, in patient 9, complete relief of dyspepsia and gain in weight Patient 10 had also complained of palpitations after food, following the gastrectomy This symptom has persisted to a lesser degree after the conversion operation and, in addition, the patient has occasional reflux of clear fluid into the mouth

The cases are summarised in the accompanying table The predominant complaints in the three patients with concomitant duodenal ulcer were related to the incompetent cardia rather than the ulcer The history of the remainder conformed to a common type, and the following is *typical*

Case 6—A man, aged 74, was admitted to the Liverpool Royal Infirmary in August, 1953, with four years' history of burning epigastric and retrosternal pain radiating to the neck and regurgitation of acid fluid into the mouth on lying down He was often wakened at night by a choking sensation due to fluid in the throat, and there were pain and difficulty in swallowing and loss of weight Probable œsophageal carcinoma had been diagnosed in another hospital

On admission clinical examination was negative Radiography showed slight spasm in the lower œsophagus and, in the Trendelenburg position, revealed a sliding hiatus hernia with incompetence of the cardia A fractional test meal showed hyperchlorhydria Retraction of the cardia and œsophagitis were confirmed at œsophagoscopy, but, in view of the patient's age, medical treatment with diet, alkalis, and an inclined sleeping posture was advised

Progress—Seven months later the patient was readmitted with no improvement in his symptoms and requested an operation Ten months after operation he is free from dyspepsia and has returned to his work as a hairdresser

All our patients obtained complete relief from their main symptoms by operation Subsequent fractional test-meal or 'Diagnex' tests have shown achlorhydria, which suggests that vagotomy and two-thirds gastrectomy do in fact protect the Roux anastomosis from the danger of stomal and jejunal ulceration which formerly led to its abandonment in the treatment of peptic ulcer In case 8, because of difficulty in exposure, vagotomy was not performed with the gastrectomy The patient remained well until three months later, when there was a recurrence of heartburn and pain on swallowing, which was relieved by alkalis Eupepsia has been restored by transthoracic vagotomy

It was feared that the entrance of bile and pancreatic juices into the alimentary tract at a distance from the stomach might interfere with normal digestion and absorption and lead to a deficiency type of post gastrectomy syndrome, but some of the patients have in fact gained weight and in none has there been a significant loss There has been no evidence of vitamin deficiency It is too soon to be sure whether or not microcytic iron-deficiency anæmia will develop, but it is, if necessary, easily corrected (Wells and Welbourn 1951)

Summary and Conclusions

Attention is drawn to the frequency of retracted cardia and gastro œsophageal reflux as a cause of dyspepsia

The diagnosis of the condition is outlined and, for its treatment, an operation which is new in this context is described It consists in vagotomy, partial gastrectomy, and re-anastomosis by the Roux-Y method

Satisfactory early results in twelve consecutive cases are summarised

THE MANAGEMENT OF CHILDREN UNDERGOING TONSILLECTOMY

PREMEDICATION WITH METHYLPENTYNOL

F R GUSTERSON
B Sc, M B Lond, F.F.A R C S
ANÆSTHETIST, WORTHING GROUP OF HOSPITALS, SUSSEX

It is estimated that every week, in Great Britain alone 1500 children undergo tonsillectomy In most cases this will be their first experience of hospital, and the responsibility for seeing that it does not cause emotional harm which may affect the child's whole life, rests largely on the anæsthetist Though much has already been written on the subject[6 14 16 17 20] *it is one which should be continually reviewed in the light of new methods*

Admission to Hospital

With a child of under 5 years of age, the important question is whether he has already learnt to adjust to separation from his mother by the normal process going to school If this has not yet happened, no amount of sedation with drugs will save him from being mentally hurt by this forced separation So important did the late Sir James Spence feel this to be that he devot much of his energies to establishing a hospital unit which mothers had to remain in hospital with th *babies It would be difficult to insist on this for* tonsil cases, but much can be done even in routi hospital work to minimise the emotional trauma

So far as is practicable, each block of admissions sho be of a similar age group The constant crying of 2-year-old can be very upsetting to a 10 year-old, in addition the older boy resents being in hosp "with kids"

The mothers of all children of age groups usu admitted to children's wards should not only bring child into hospital but should give him his first bath put on his night-clothes, which could, with advant be the child's own Many children feel more secure their own clothes The time of admission is import and should never be *in the morning unless* th absolutely unavoidable To put a young child to in the morning is synonymous with punishment first meal in hospital should be given by the mot aided by the nurse who will look after the child. raises a very important point The number of pe dealing with the child should be as small as possib ideally one nurse only, *who will thus become* temporary mother substitute

While the mother is still present, the child sho meet as many as possible of the people whom he will next day, including theatre porters All these pers should be chosen for their ability to handle childre there is a type of hospital porter who would frighten child out of its wits *If not already done at home,* would be a *good time to tell the child* exactly what happen the following day

One point which should be emphasised is the imp tance of the child's bringing into hospital some favou toy, however shabby This is brought out very well Robertson's[28] film, in which the toy is a piece of well chewed *blanket* The toy will be *returned* the child, *for the old idea of infection* being transmit *in* this way is no longer held This toy will natur accompany the child to the operating theatre, which the end of a morning's list may thus look rather lik scene from a Walt Disney cartoon The toy must be in the cot when the child wakes up

On the Way to the Operating-theatre

If the child is not asleep when his time comes to to the theatre he should never be made to lie down the trolley *To lie flat on the back while being wh* along corridors is very *frightening* The operat hould be carefully timed even when this means some nconvenience All operations on children should be done as early as possible in the day A child will tolerate the absence of his breakfast, but the absence of dinner s well, particularly if other children in the ward are having theirs, is really putting too great a strain on his control

Two more simple points are worthy of mention here The first is the old fashioned practice of making the child wear a mackintosh cap and bib for tonsillectomy With modern surgical techniques this surely is no longer necessary, and the children are much happier without them.

The other point is the wearing of face masks by the theatre staff It is most important that every person handling a child on his way to the theatre and in the anæsthetic room should have the face fully exposed Half masked faces are extremely frightening to children and it is a great help to the child to be able to recognise his ward nurse

Sedation

Many anæsthetists feel that to avoid any possible emotional upset all children of whatever age should be completely asleep before leaving the ward for the theatre This would in many ways be ideal provided that the perfect drug or combination of drugs could be found ven so the remarks in the foregoing paragraphs still pply to the time before and after the child has its actual eration and I suggest that however perfect the asleep in the ward ' technique is some case will occur here sedation is incomplete Many think although it difficult to prove that in the resulting partially dis ientated state a child is even more impressionable than hen fully conscious This certainly applies to adults many will remember from the early days of the use barbiturates by mouth for premedication

Innumerable methods have already been used to nsure that every child is fully asleep before leaving the ard, and each has its enthusiastic advocates Having ied them all I have given them up one by one Person ly, I feel that the rectal administration of drugs to ildren should be avoided except when absolutely ecessary Children may not like an injection or a nasty edicine but that is an affair of the moment that a ild can have explained to it. Not so with rectal terference, and the very young child is also psycho gically sensitive about its rectum Hence while mitting the safety of rectal paraldehyde and the noothness of rectal thiopentone I cannot agree that ey should be used as a routine practice Furthermore did find when using rectal paraldehyde in children some ears ago that many had postoperative pyrexia and for everal days were not fit to return home The dis dvantages of any barbiturate (see below) are also pplicable to rectal thiopentone

I have also used morphine for premedication either as orphine and atropine or as Omnopon and hyoscine, sing the dosage schedules advocated by various orkers[3,16] I was immediately confronted with an crease in postoperative vomiting and complaints from he ward sister that quite a number of children were angerously depressed on return to the ward, and that reat difficulty was experienced in keeping their airways lear The dosage of these extremely potent drugs is mall and minute errors can have serious consequences

At present the drugs most popular for premedication re pentobarbitone ('Nembutal') and quinalbarbitone 'Seconal') Though undoubtedly satisfactory in many ases these have very grave disadvantages I have ound very little to choose between them and I wonder hether it would be possible to differentiate between hese two drugs by purely clinical assessment The ollowing remarks about pentobarbitone therefore apply qually to quinalbarbitone

Barbiturates

In the first paper on pentobarbitone in this country Magill[31] wrote

> ' As with other barbiturates the variable reaction of individuals to nembutal renders the dosage by mouth and by rectum difficult to determine beforehand This is especially noticeable in children. In general, it may be stated that children are more resistant than adults and in children the variation has little to do with age or development For example, one well-developed child age 7 was fast asleep after the administration of grs. $1^{1}/_{4}$, while another child aged 6 and of small physique was quiescent but not asleep after grs. 3 had been given.
>
> He further said that ' Irrespective of the dose or method of administration, a variable degree of restlessness was noted during the immediate post-operative period in 13 patients Five were children and their condition was controlled by potassium bromide

Waddy[30] confirmed the postoperative restlessness and in subsequent articles on these drugs the same two drawbacks of uncertainty of effect and postoperative restlessness have been mentioned[4,6,12,18,22] This still applies, even if in a lesser degree, when the drug is given rectally

Postoperative restlessness is a more serious problem than this uncertainty of dosage, and can be so great that a single nurse can hardly control the child A wardful of such children is in a real state of pandemonium, which can be reduced to a manageable degree only by giving morphine or one of its derivatives.

From the state of uncontrolled restlessness it is so easy to pass to that of an uncontrolled airway serious enough after any operation but liable to be extremely dangerous *after an operation* on tonsils and adenoids By whichever method the operation is done, blood is apt to accumulate in the upper respiratory passages Again even if the airway is not obstructed there is the very real risk that blood and mucus will be inhaled into the lungs during the state of respiratory depression which may follow the giving of morphine after a barbiturate

I was delighted to see attention drawn to this by Fraser[9] and Middleton Price[24] The situation is often made worse by ordering further morphine to control the hæmorrhage I recently had experience of such a case and at necropsy the lungs were full of inhaled blood which had without doubt been the cause *of death I have indirect knowledge of other* such cases which could usefully be made known and discussed Even if this complication occurs only in 1 case in 2000 it is too high a price to pay for the doubtful advantage of the child's being asleep before leaving the ward.

A much less important difficulty with these barbiturate preparations is that of administration They all have an extremely unpleasant and long lasting taste and hence are supplied in capsules Nurses have developed many ingenious ways of administering these but often several mouthfuls of water are given When there has been some emotional upset during the attempt to swallow the capsules this may not be absorbed from the stomach, with the result that the child vomits during the induction of anæsthesia Also in such cases the drug has not usually been absorbed and the child is still awake, thereby losing the whole purpose of this method. The drug may become absorbed later, another factor contributing to postoperative respiratory depression With these draw*backs in mind I had* for some time relied on atropine alone for premedication induction usually being by intravenous thiopentone—a technique used by many others But in spite of the most careful handling about 20% of the children were obviously much upset by the visit to the theatre and yet another injection

Methylpentynol

The advent of methylpentynol therefore seemed to offer a via media between the dangers of a barbiturate and the disadvantages of no preoperative sedation All the early reports[2 7 10 11 13 22 23 25 26] of its use as a hypnotic emphasise the absence of side effects, especially respiratory depression and alteration of blood-pressure or pulse Methylpentynol was reported as having a specific effect in allaying fear and apprehension, even in doses where actual sleep was not obtained It is available commercially as a flavoured coloured elixir of ‘Oblivon’ (British Schering) containing 250 mg of methylpentynol per teaspoonful The flavour cannot be described as pleasant—it vaguely suggests paraldehyde—but in actual practice children very rarely complain about it

As soon as this investigation was planned, it became necessary to find some method of recording the children's reactions which would be impersonal and in no way subject to bias or prejudice It was decided to follow the work of Robertson of the Tavistock Clinic and make a film record showing children's reactions with different forms of premedication Cases were chosen at random by the camera operator from routine operating-lists This film is now available and demonstrates better than words the reactions of the children In nearly every case the child looks happy not only on going up to the theatre but also—perhaps more important still—on waking up in the ward afterwards

We soon found that in many cases the doses recommended by the makers had little effect We now give two teaspoonfuls for children aged 2–4 years, three teaspoonfuls for children of 4–8 (varying slightly with the build or temperament of the child), and four teaspoonfuls for children of 8–10 The methylpentynol should be given an hour before the anæsthetic, and the atropine can then be given half an hour later, when the child is much less upset by having an injection With these larger doses the children nearly all arrived in the anæsthetic room quiet and apparently unperturbed, some actually asleep though easily aroused Brown and Ellis[5] confirm the great safety margin of methylpentynol

In nearly every case anæsthesia was induced with a “sleep dose” of intravenous thiopentone This is a safe and easy procedure in a quiet and peaceful child, but the possibility of an intra-arterial injection has always to be borne in mind Attention was first drawn to this by Macintosh and Heyworth,[19] but there should be no difficulty in these cases, because the child will cry at once if the artery is touched If the child cries at all, the position of the needle must be checked, and, if there is any doubt, the injection is not continued Instead it is quite easy to induce anæsthesia with nitrous oxide without distress to the child

With this method no difficulty from vomiting in induction (Rendell[27]) has been observed, nor has there been any increase in postoperative vomiting I think the difference in my series (which now extends to more than 500 cases) is due to the fact that the methyl pentynol has been given early enough to be absorbed from the stomach

The ward immediately commented on the greatly decreased degree of postoperative restlessness in children premedicated with methylpentynol Children given no postoperative ‘Nepenthe’ were carefully watched and showed little restlessness, what little there was ceased in a few minutes No special control was required Absence of respiratory depression was quite obvious, and the children could keep their own airways clear even if they rolled over on to their backs This was equally true after an injection of nepenthe minim 1 per year of age With such a dose the children all remained peacefully asleep, and it is now our routine to give this injection as soon as the child shows signs of returning to consciousness

Before deciding on the value of this new method of preoperative sedation it was necessary to study it from the child's point of view A survey of these children was therefore undertaken along the lines o Albany Research Project[1] An experienced psych social worker was employed who also had a know of general hospital routine and an understandi children She was given the admission lists fro record department of the hospital and chose 100 ca random I did not know which cases she had visite she did not know what anæsthetic technique had used in any particular case Thus any possible b opinion was eliminated. The children chosen visited in their homes about a week before admissio again several days after their return home Many of children were visited several times in a period up to weeks after their discharge from hospital

Several interesting factors emerged from this in gation The first was the great advantage of a “by somebody from the hospital” The child's m and the child had the whole episode explained in s non-technical language It would be an excellent w reducing fear of hospital if this could be done in e case, if not, perhaps a simple letter explaining routine in hospital could be sent with the admi note

The questionnaire is shown in the accompan figure This is quite a simple form because it was considered advisable to make each child into a psy logical study, but all the necessary facts are incl in it

The numbers of children receiving pentobarbitone methylpentynol were almost equal This was q fortuitous At once it was evident that the propor of children disliking their hospital experience was eq in each case (see table)

GENERAL COMMENTS

REACTION TO STAY IN HOSPITAL

—	Received pentobarbitone	Received methylpenty
No of children	51	49
Reaction favourable	40	39
Reaction unfavourable	11	10

'he "unfavourable reactors" varied in their com laints Most mentioned specifically a dislike of pricks," while others merely mentioned that they did ot like having to sleep in a room with the lights on or hat they did not like the food

The number of children showing any real emotional pset was quite small in each series. Of those receiving entobarbitone 3 showed increase of nightmares and of hose receiving methylpentynol 5 showed emotional upset uch as crying at night, and disinclination to return to chool Children showing this emotional upset were all nder 6 years old

It is therefore fair to deduce from this admittedly mall survey that there is no specific advantage from the hild's point of view in heavy preoperative sedation that btained with methylpentynol being adequate to prevent any appreciable psychological trauma

The number of children mentioning an objection to the njection was considerable, and equal in each series This ed me to think of some method of avoiding the injection of atropine At first the atropine was dissolved in a ittle water in doses of gr $^{1}/_{100}$–$^{1}/_{50}$ according to age, nd this solution was added to the elixir This had a efinitely adverse effect on the not too pleasant taste of he elixir and in addition the children were not dry nough for comfort during induction or operation At he same time it was thought that the sedation obtained as not so good, but since secretions were not adequately controlled, only a few cases were investigated

Hyoscine was next used in the same way in doses of $^{1}/_{150}$–$^{1}/_{75}$ This did not affect the taste of the xir and in every case the drying effect was satis tory In addition there was a much greater sedative ect. Nearly every child arrived in the anæsthetic om actually asleep, although easily aroused. In the stoperative stage there was no restlessness and even nepenthe was given the children were quite easily oused. The ward nurses in fact commented that the ildren seemed to sleep naturally for the rest of the day ter returning to the ward although they could be used quite easily and given a drink after which they ietly settled down and returned to sleep This modifi tion has not yet been used in many cases but so far ows great promise

It thus seems that methylpentynol, given as elixir of ethylpentynol provides a safe and reliable premedica on for children There is no increase in emotional set even if the children are not actually asleep on rival in the anæsthetic room Induction of anæsthesia ith a sleep dose of intravenous thiopentone gives a very nooth and pleasant induction and there is no danger of stoperative respiratory depression The addition of yoscine to the methylpentynol by mouth thereby voiding two injections, is at the moment being investi ated and shows every prospect of being successful

Summary

It is important to avoid emotional trauma in children dmitted to hospital for tonsillectomy especially when ey are under 5 years of age

Simple points in the management of children during eir stay in hospital are outlined

The disadvantages and dangers of using barbiturates r preoperative sedation are discussed

The use of methylpentynol in a flavoured elixir for eoperative sedation is described A follow up of 100 ses showed no difference between the emotional response f those children sedated with pentobarbitone and those ceiving methylpentynol Methylpentynol has a great fety margin and none of the disadvantages of the rbiturates

A sound film has been made illustrating the points the paper

I am indebted to Mr H G Downer and Mr P C Rushton hose cases these were and who performed all the operations I wish to acknowledge the very great help and coöperation I have received from the nurses of the E N T wards of Worthing Hospital. The children were visited by Mrs. E E Nevell, some time psychiatric social worker attached to Graylingwell Hospital The expenses of this investigation and of making the film were met by a grant from the research funds of the South West Metropolitan Regional Hospital Board. The photography was under the charge of Mr J Howard Dr R Mac Keith helped with the script of the film

CHEMICALLY IDENTIFIABLE BACTERIAL RESIDUES IN LUNG LESIONS

R Consden

The syndrome described by Caplan (1953) in coal miners with pneumoconiosis consists in the development of radiologically characteristic pulmonary nodules in patients with concomitant rheumatoid arthritis In a community of South Wales coalminers Miall, Caplan Cochrane Kilpatrick and Oldham (1953) found that more than half the men with this characteristic X ray picture also had rheumatoid arthritis compared with only 3% of those with ordinary progressive massive fibrosis

Because of our work on the chemistry of the subcutaneous nodules of rheumatic fever (Consden Glynn and Stanier 1953) we were invited by the South Wales investigators to study the chemistry of these various lung lesions with a view to confirming the difference between the Caplan nodule and other forms of pneumoconiotic fibrosis In the course of this work we found that in some samples the hydrolysates appeared to contain α ε diaminopimelic acid (D A P) when examined by paper chromatography Since this amino acid is not a normal constituent of mammalian tissue but is widely distributed among bacteria of various genera and species including *Mycobacterium tuberculosis* it seemed important to establish with more certainty that D A P was present especially as infection was no longer demonstrable by the usual methods of microscopy, culture, and animal inoculation This method of detection is presented below

Tissues Studied

(1) *A caseous nodule* obtained by biopsy from a man aged 23 was a typical caseous tuberculoma 1 5–2 0 cm in diameter with an acellular non-fibrous necrotic centre surrounded by a zone of cellular fibrous tissue 2–3 mm thick Occasional foci of epithelioid and giant cells were present in this cellular zone No acid fast bacilli were found despite prolonged search of several sections

(2) *Tuberculous lung tissue* obtained by biopsy from a woman aged 28 contained several dense fibrous foci acellular in the centre and only slightly cellular at the periphery The apparently necrotic centre, when stained by Gomori's (1937) method for reticulin, revealed a dense network of fine and coarse collagen fibres with some still finer argyrophil fibrils interspersed with them No tissue histologically characteristic of tuberculosis was seen, and no acid fast bacilli were found

(3) *Progressive massive fibrosis* a sample removed at necropsy from a man aged 55 consisted of jet black and fairly dense fibrous tissue about 1 cm in diameter and surrounded by a narrow margin of emphysematous lung The main fibrous lesion consisted of a dense central network of collagen with a surrounding fibrous capsule radiating into the surrounding lung Similar but smaller nodules were present in the adjacent lung tissue The acellularity of the fibrous tissue was striking

(4) *Infective nodules* obtained at necropsy from a man aged 57 consisted of densely pigmented lung with diffuse fibrosis and some nodules up to 2 mm in diameter formed of interlacing collagen fibres. Cellular reaction was virtually absent from the fibrous areas and the intervening lung tissue

(5) *A Caplan nodule* obtained at biopsy from a man aged 52 was a sharply defined lesion about 1 5 cm in diameter Histologically the main central part of the nodule appeared structureless or faintly fibrillar when stained with hæmatoxylin and eosin, but with silver impregnation this central area was seen to be composed of a dense network of collagen fibres with finer argyrophil fibrils in the interstices Peripherally there was a band of cellular tissue containing fibroblasts and foci of lymphocytes and histiocytes, but the cells were not in a palisade formation The microscopic appearance lacked the characteristics of tuberculosis, and the structure of the acellular centre was quite different from that of the subcutaneous nodules of rheumatoid arthritis

(6) *Normal lung removed* at necropsy from a male town dweller, aged 59, who died of congestive cardiac failure consisted mainly of the dark dusty surface and was used as a control of the other lung specimens

Method of Demonstrating D A P in Lung Lesions

Samples of all the lung tissues were washed with 0 8% saline solution followed by distilled water, dehydrated in acetone, and autoclaved to remove collagen Tests for D A P as described below were made on the residues, since preliminary chromatography had indicated that in tissues which contained this amino acid, the bulk of it was not extracted by autoclaving This procedure therefore has the advantage of concentrating the D A P-containing constituents in the test material, because from a half to two-thirds of the organic material of the lung samples was removed by autoclaving The residues of Caplan nodule, tuberculous lesion, and progressive massive fibrosis after autoclaving contained about one-third of the original organic matter, whereas the infective nodule and caseous nodule residues contained about one-half

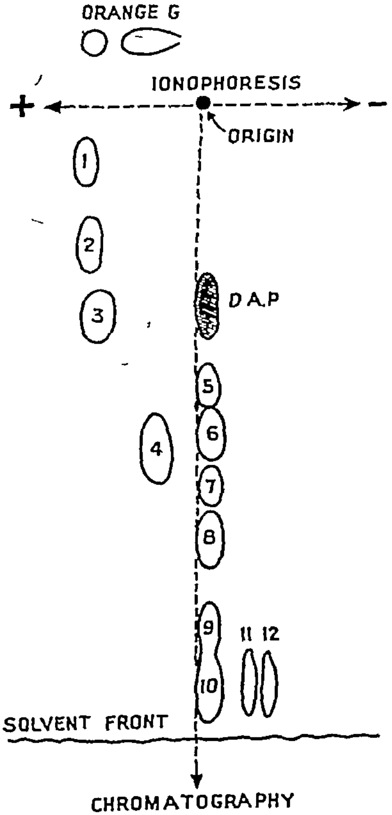
The following simple test for D A P depends on a two-dimensional separation on paper by chromatography followed by ionophoresis at right angles to the direction of chromatography

The tissue was hydrolysed with 6 N HCl at 105–110°C for 17 hours Excess acid was removed by evaporation in vacuo Insoluble humin was separated by centrifugation A portion of the hydrolysate was treated with excess bromine water and stood for 5 minutes Excess bromine and acid were removed by evacuation over KOH. The treated hydrolysate was concentrated to a suitable volume, and 5–10 µl containing the equivalent of 0 25–0 33 mg of protein was placed o spot half-way across a sheet of Whatman no 1 filter pa 24 cm wide Chromatography was carried out in wa saturated phenol in an atmosphere of NH_3 (produced fr 0 3% NH_3 on the floor of the chamber) for 21–24 hr., which time the solvent front had travelled about 25 c from the origin. The sheet was thoroughly dried and the pa below the solvent front removed The remainder was suspen and sprayed lightly and evenly with M/20 phosphate buff pH 7, the spraying being done first on either side of t chromatogram and finally along the chromatogram itse The wet sheet was then placed in position in the pap electrophoresis apparatus with the edges of the paper dipp into the electrode compartments containing M/20 phospha buffer, pH 7 The apparatus consisted of a flat shall 'Perspex' box designed for holding paper in a horizont position Before the current was applied, a drop of Orange solution was placed above the origin to act as a control. T voltage applied was about 14 V per cm, and the start current 0 5 mA per cm of width The current was pas for 1 hour, after which the paper was removed, dried, a treated in the usual way with ninhydrin During the io phoresis the Orange G separates into two components (r and yellow) The faster (yellow) travels at a similar rate aspartic acid and hence is useful for observing progress dur the run The resulting two dimensional separation (chroma phoretogram) is illustrated diagrammatically in the acco panying figure

In phenol NH_3 the amino acids which would interfere w D.A.P are glutamic acid, ethanolamine phosphoric acid, a cystine, all of which occur in animal tissues. The first t because of their acidic nature, migrate towards the an in an electric field Cystine is completely oxidised Br_2 to cysteic acid (Consden et al 1946), which bes having a lower R_F value than D.A.P, is also acidic D.A behaves li the monoami monocarbox acids and migra slowly towards cathode becaus electro endosmo and no kno amino acid of animal tiss hydrolysate wo occupy the s position after two dimensio separation Ty sine, if present converted by bromine to dib motyrosine, wh migrates slow towards the an at pH 7 and h an R_F value phenol similar glycine The ba amino-aci migrate towar the cathode

Work an Dewey (1953) de cribe a method demonstratin D.A.P, based similar princip but this is mo laborious an time consumi than the meth described abov

A number o solvents can b used for the f chromatograph separation bet the interfer components



Chromatophoretogram of a bromine-oxidised protein *hydrolysate containing* diaminopimelic acid (chromatography in phenol-NH_3 *followed by ionophoresis at pH 7*)

D.A.P, *diaminopimelic* acid 1 cysteic acid 2, aspartic acid 3 glutamic acid (ethanolamine/phosphoric acid if present, would *occur here*) 4, dibromotyrosine 5 serine 6, glycine 7 threonine 8 alanine 9 valine 10 leucine &c. 11 arginine 12, *lysine*.

be subsequently separated by ionophoresis or converted to acidic amino-acids by oxidation. However, solvents which incorporate acid are a disadvantage because it is impossible subsequently to remove all the acid from the paper. This increases the ionic strength of the buffer and hence causes too high a current for convenience in the ionophoretic separation. Further, if ethanolamine phosphoric acid were present it would only have appreciable ionophoretic mobility at pH 6 or higher (Clarke et al. 1955). The acid in the paper would therefore require stronger buffer solutions to raise the pH sufficiently, and this would also cause high current. This could be overcome by using a lower voltage, but the time of ionophoresis would be correspondingly increased. The width of the sheet is not important; it depends on the dimensions of the paper-electrophoresis apparatus used.

Results

The lower limit of detection of D.A.P. is about 0·5 μg.

Hydrolysed fat-extracted *M. tuberculosis* by the above test showed a moderately strong D.A.P. spot corresponding to about 5·0 μg. Caseous tissue showed a spot of moderate strength (about 2·0–3·0 μg.); the Caplan nodule showed a faint but quite distinct spot (about 1·0 μg.), and a trace (about 0·5 μg.) was found in the non-caseous tuberculous lung. No D.A.P. was detected in the infective nodule, in the sample of progressive massive fibrosis, or in the normal lung.

Discussion

D.A.P. was first observed in *Corynebacterium diphtheriae* by Work (1949) and in *M. tuberculosis* by Asselineau and Lederer (1950). Subsequently many investigations have shown its wide occurrence in bacteria (see Work and Dewey 1953), but it has not been demonstrated in either tissue fluids or tissue hydrolysates of mammals.

The ability to demonstrate D.A.P. even in minute quantities in samples of lung tissue indicates heavy bacterial colonisation at some period in the evolution of the lung lesion. Since the method used cannot detect less than about 0·5 μg. of D.A.P., the concentration of this amino-acid in the positive specimens must have exceeded 1·5–2·0 μg. per mg. But D.A.P. only constitutes some 2% of the dry weight of those bacteria likely to occur in lung; 1·5–2·0 μg. therefore represents 75–100 μg. of dry bacillus weight. This is present in the residue after autoclaving; and, assuming that only negligible amounts of D.A.P. are extracted by autoclaving, evidence is thus obtained that lung lesions, despite the absence of cultural or histological evidence of infection, may contain identifiable bacterial residues resulting from a weight of infection amounting to at least 2·5% of the dry weight of the lesion itself.

Moreover, with the caseous material the strength of the D.A.P. spot suggested that the bacterial contribution to the lesion was much higher, amounting to at least 20% of the lesion. These figures must not be taken as evidence that bacterial debris is actually present to this extent, since the bulk of the organisms may well have been removed by the normal scavenging and enzymatic activities of the tissues. On this hypothesis D.A.P. should be a component of the highly resistant residue of the bacteria. That this is so for *M. tuberculosis* has been shown by Colover and Consden (unpublished) in a chemical study of the fraction of the tubercle bacillus that is active in the experimental production of allergic encephalitis (Colover 1954). An active residue remaining after prolonged extraction with fat solvents, followed by digestion with proteolytic enzymes, still contained D.A.P. in readily detectable amounts. Some mention should be made of presence of D.A.P. in the Caplan nodule and its absence in progressive massive fibrosis. Further investigation of the latter is necessary before this difference is established. Prior bacterial infection might be an important factor in pathogenesis of one or both of these conditions.

Two further aspects of these results are worthy of comment.

(1) The detection of bacterial debris by the presence of chemically characteristic components might well prove a useful method in the study of lesions of obscure ætiology, such as *sarcoidosis*. *The presence of either arabinose, rhamnose, or* mycolic acid would provide further confirmation of the presence of such bacterial residues.

(2) In view of the rôle of tubercle bacilli in the experimental genesis of immunity and allergy, the persistence in the tissues of resistant bacterial fractions might be of great significance.

Summary

A method is described for identifying α ε diamino pimelic acid in some lung lesions.

This amino acid was found in a caseous tuberculous nodule, a Caplan nodule, and a sample of non-caseous tuberculous lung tissue. It was not found in a sample of "progressive massive fibrosis" nor in an "infective nodule."

The bacterial residues in the caseous nodule represent a weight of infection amounting to about 20% of the dry weight of the lesion.

It is a pleasure to acknowledge the coöperation of Dr. J. Gilson, Dr. W. E. Miall, Dr. D. Rivers, and Dr. A. L. Cochrane, of the Pneumoconiosis Research Unit, for supplying tissues and for helpful discussion. The infective nodule was provided by Prof. J. Gough.

SIMPLIFIED OPERATIVE ROUTINE FOR CARCINOMATOUS OBSTRUCTION OF COLON

B. N. Brooke
M.D. Birm., M.Chir. Camb., F.R.C.S.
READER IN SURGERY, UNIVERSITY OF BIRMINGHAM

For the treatment of acute colonic obstruction due to neoplasm it has been usual either to do the Paul-Mikulicz operation or to relieve obstruction with a colostomy, later resect the lesion, and finally close the phase of acute obstruction if the two stage procedure is planned It is to draw attention to the value of this method that the following three cases are reported

Case-reports

Case 1 —A woman, aged 70, was admitted on Feb 22, 1954, to the Queen Elizabeth Hospital with acute obstruction of the colon Laparotomy next morning revealed a mobile growth of the rectosigmoid A loop colostomy was constructed in the left iliac fossa as close to the lesion as possible After operation an infected hæmatoma formed in the wound Sixteen days after admission the abdomen was reopened through a low left paramedian incision, thus avoiding the previous site on the right side It was confirmed that the neoplasm of the rectosigmoid was at an early stage , no glands were palpable, and so anterior resection was undertaken The colostomy was detached from the abdominal wall and withdrawn into the abdominal cavity From that moment it was possible to do an anterior resection in the usual manner removing the growth within the pelvis after mobilising the upper rectum and ligating the superior hæmorrhoidal vessels , end to end anastomosis between the mobilised portion of the descending colon and the rectum at the level of the pelvic peritoneal reflexion was a simple matter after removing the sigmoid and rectosigmoid, which contained both growth and colostomy The operation was completed by suture of the laparotomy and colostomy wounds, the latter being drained Recovery was uneventful, and the patient returned home two weeks after the second operation

Case 2 was similar to case 1 as regards site of the neoplasm, but the technique of removal was somewhat different A man, aged 53, was admitted on March 24, 1954, with intestinal obstruction due to a growth found at laparotomy to be adjacent to the brim of the true pelvis The sigmoid loop was long , at the lowest possible site a colostomy was formed in the left iliac fossa After this operation the sigmoid tended to prolapse through the colostomy incision Ten days later the abdomen was reopened through the lower left paramedian incision Because of the bulk of colon exteriorised as the result of prolapse at the colostomy, it was decided to perform the dissection through the paramedian incision but deliver the resected portion through the colostomy wound, so as to avoid contamination which might result from returning the prolapsed portion and the colostomy to the abdomen The splenic flexure was mobilised, and since it was impossible to dissect in the lower part of the left paracolic gutter, the left colonic vessels were ligated at their origin from the medial side, and special care was necessary to avoid injuring the ureter An anterior resection was done with end to end anastomosis between the upper descending colon and the rectum The colostomy and the neoplasm were excised together in the length of colon removed through the colostomy incision The paracolic gutter was drained through the wound in the left iliac fossa which was repaired Convalescence was smooth and the patient returned home twelve days after operation

In Case 3, a woman aged 61, the lesion was at the splenic flexure The preliminary laparatomy was done through a lower left paramedian approach , and the colostomy, placed as far to the left in the transverse colon as possible was brought out above the level of the umbilicus through a left trans rectal incision Fourteen days later the left paramedian incision was reopened and was continued upwards to include the colostomy wound and detach the colostomy An excellent exposure was thus obtained, and left hemicolectomy was done with end to end anastomosis of the right trans verse colon to the lower sigmoid The paracolic gutter was drained through a stab incision in the flank, and corrugated rubber was placed at the site of the pre-existing colostomy The patient had an undisturbed convalescence and was discharged twelve days later

Management before resection in all cases has included colostomy washouts , and by mouth for three days streptomycin 1 g twice daily, alternatively oxytetracycline 250 mg six hourly, or phthalylsulphathiazole 2 g thrice daily, with the same drug instilled as a suspension into the distal loop of the colostomy At operation it has been found best to tie a dry swab over the colostomy and to make no attempt to close its opening with sutures, since this tends to be ineffective and promote bleeding and thus the possible spread of contaminants In the first case oxytetracycline, and in the second case streptomycin, was instilled around the area of dissection and anastomosis before closing the peritoneum This was done because of the wound infection complicating the one, and the prolapse increasing the possibility of contamination in the other , no local application of this sort was made in the third patient Case 1 was given oxytetracycline after operation because pus from the previous incision was encountered on reopening the abdomen No drugs of this sort were given to cases 2 and 3 after operation, and routine chemotherapy is avoided at this stage since these drugs are better kept in reserve for possible complications

The neoplasm itself has always been covered at an early stage with a surgeon's mask, the strings of which are tied tightly around the bowel above and below the lesion to prevent exfoliated malignant cells from spreading to the site of anastomosis, where they may be implanted (Cole 1952) while the mask itself prevents direct exfoliation and implantation due to manipulation

Conclusions

A method is described for treating carcinomatous obstruction of the colon and rectosigmoid At the initial operation to relieve obstruction, the colostomy is placed as close to the growth as possible so that both may be resected together at a second and final operation

The advantages include a reduction from three to two in the number of operative stages and therefore reduced risk of morbidity , shorter stay in hospital , and greater freedom of manœuvre, permitting wider excision of the area of lymphatic spread

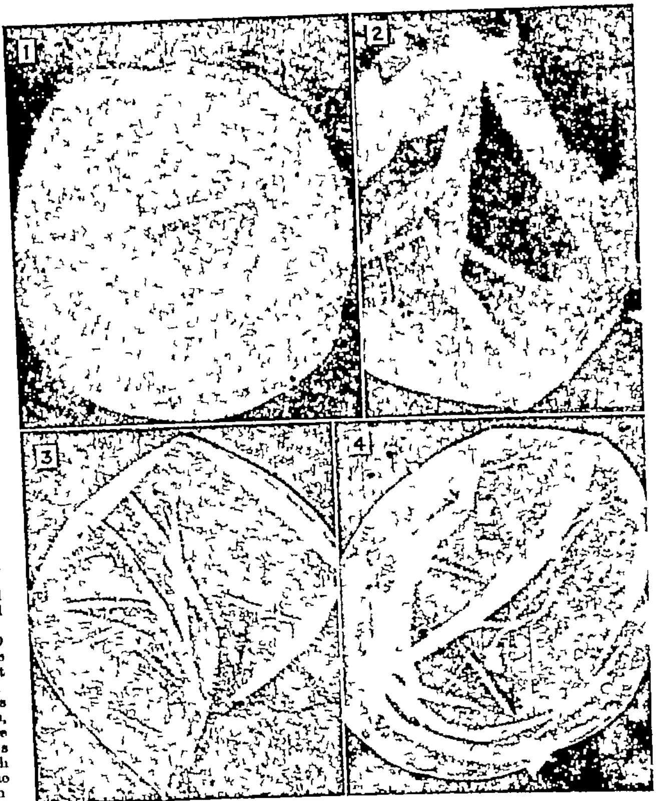
Chronic hæmolytic anæmia with paroxysmal nocturnal hæmoglobinuria (P N H) is fairly rare Crosby (195[illegible]) remarks that 162 cases have been reported since Marchiafava's first description in 1928, but probably the true incidence is much greater The ætiology is unknown The present concept is of a cell defect shared by erythrocytes, leucocytes, and platelets This defect of unknown nature but possibly one of cell stroma protein, renders the erythrocyte abnormally susceptible to a hæmolytic system present in normal plasma

It has been claimed that electron microscopy in some cases has shown abnormal structure in the envelope of the hæmolysed red cell (Matthes et al 1951) Electron microscopy in the case presented below did not support this contention

Case-report

A married woman, aged 35, with one child aged 11 years and no history of any previous illness of consequence, first noticed hæmoglobinuria in 1943 while she was pregnant She had it on only one occasion, but she was found, during the puerperium, to have a mild anæmia which did not respond to iron therapy She remained in her usual health thereafter until August, 1953, when she was admitted to hospital as a contact carrier of *Salmonella typhimurium* She was given a course of oxytetracycline, after which her stools were negative



Appearance of normal and P N H erythrocyte ghosts on electron microscopy: 1 normal erythrocyte unshadowed (× 8000); 2, P N H erythrocyte unshadowed (× 12,000); 3 normal erythrocyte shadowed with Au and Pd (× 8000); 4 P.N H. erythrocyte shadowed with Au and Pd (× 8000)

pathogens. She was again found have an anæmia not responding iron. Shortly afterwards hæmo bulinuria recurred being present the first morning specimen of ne but not at other times of the y Her doctor detected slight ndice which remained, with me fluctuation until readmission hospital in December 1953 The tient felt tired and weak and d spells of dizziness in the morn g lasting about an hour She new by a feeling of general malaise hen she would pass bloodstained rine. There was no history of næmia or jaundice in her family r of exposure to hæmolytic drugs

The patient was a small and slimly built young woman who was pale and had a lemon yellow tint and a few soft and slightly enlarged glands on either side of the neck but not elsewhere No enlargement of liver or spleen was detected No abnormality was found in the cardiovascular respiratory nervous or alimentary systems. The morning urine was the colour of port wine and contained albumin but no bile

Laboratory Investigations.—Examination of the blood showed Hb 9·8 g per 100 ml red cells 3,030 000 per c.mm., and white cells 5400 per c.mm A red-cell fragility test showed that hæmolysis began in 0·5% solution and was complete in 0·35% (control 0·45% and 0·4% respectively) The blood group was A Rh D positive The probable genotype was R2 r (c̄DE c̄de) The direct Coombs test was negative; and when the patient's serum was tested against a large panel of cells, no irregular antibodies were detected Ham's test and Crosby's modification of Ham's test both showed strong hæmolysis of the patient's cells by homologous serum whereas there was no hæmolysis in the control tests. In addition the patient's cells were incubated with an anti A serum which contained a weak anti A hæmolysin; the control cells showed slight hæmolysis, whereas the patient's cells were considerably hæmolysed The Wassermann and Donath Landsteiner tests were negative Between periods of hæmoglobinuria the serum contained small amounts of oxyhæmoglobin and considerable amounts of methæmalbumin Shortly after the passing of dark urine it contained a large amount of oxyhæmoglobin and a small amount of methæmalbumin. The methæmalbumin was never demonstrable spectroscopically and was only detected by plotting absorption curves on a spectrophotometer Electrophoresis of the serum did not reveal any abnormality; likewise electrophoresis of the hæmoglobin within the cells revealed no difference in mobility from that of control samples The dark samples of urine contained variable amounts of methæmoglobin and oxyhæmoglobin. When the urine was freshly passed the amount of methæmoglobin was usually considerable but on standing it disappeared rapidly increasing alkalinity converting it to oxyhæmoglobin. The deposit revealed a few hyaline casts numerous squamous epithelial cells (a small proportion of which contained iron granules within the cells) and very numerous amorphous particles of iron-containing material. No red blood-cells were seen. The urinary excretion of urobilinogen was 3 mg daily The fæces were of normal colour The fæcal excretion of urobilinogen was 238 mg daily

Progress.—Hæmoglobinuria ceased spontaneously after five weeks. It has not so far recurred but there has been no improvement in the anæmia. The patient's general condition remains moderately satisfactory There have been no thrombotic or infective complications For these reasons it has not been deemed advisable to give a transfusion of washed cells or anticoagulant drugs which may have a temporary ameliorating effect on hæmolysis

Electron Microscopy.—The patient's red cells were examined by electron microscopy and some of the results are shown in comparison with those of normal cells in the accompanying figure The cells, obtained from samples prepared as shown below were separated from plasma or from serum by spinning and hæmolysed with 5 10 or 30 volumes of water The envelopes were separated by centrifuging and were treated with 1% osmium tetroxide for 30 minutes The material was again spun, washed resuspended to a suitable concentration and sprayed on to a supporting film for microscopy Some films were shadowed with gold and palladium at 15 C The following preparations were examined thus: (1) citrated blood; (2) cells from blood allowed to clot spontaneously; (3) cells from blood defibrinated by shaking with glass beads (4) cells from blood defibrinated by stirring with a glass rod; (5) as (3) but after allowing the blood to stand for some days before defibrinating; and (6) as (4) but allowing the blood to stand for some days. Samples 4 5, and 6 were unshadowed None of the photographs showed any significant differences between normal and P.N.H cells. There was no evidence of the spotty or "mesh like" appearance described by Matthes et al (1951)

Discussion

The lytic mechanism in P N H has been studied by many workers, notably Crosby (1953) and Crosby and Bell (1951), the current views and the literature being well reviewed by Crosby (1953) It has been shown that both lytic and inhibitory factors are present in normal plasma, but that the abnormality in P N H does not lie in these factors If P N H cells are placed in normal plasma they tend to undergo lysis, this process being hastened by acidification, normal erythrocytes are not lysed by P N H plasma This explains why transfusion of a P N H patient with normal blood tends to produce a lytic crisis The system present in the normal transfused plasma attacks the abnormal cells of the patient If washed cells only are given, the normal plasma system being absent, no lysis results

Despite much examination no satisfactory explanation is forthcoming for the widely observed tendency of P N H patients to get lysis during sleep It has been repeatedly suggested that diminished excretion of respiratory carbon dioxide during sleep reduces the plasma pH (T H Ham 1939, G C Ham and Horack 1941, Matthes et al 1951), but the evidence for this is not entirely conclusive (Peterson 1949, Crosby and Bell 1951) From in-vitro experiments Peterson (1949) suggested that carbon dioxide has some specific effect not shared by other acids, but Crosby and Bell (1951) and Ham (1939) could not confirm this It appears clear that the lytic tendency is associated with sleep as such and not with posture or time of day Increase of pulmonary ventilation in a respirator during sleep will prevent lysis (Ham 1939, Ham and Horack 1941)

Paroxysmal nocturnal hæmoglobinuria does not appear to be hereditary, only one of a pair of uniovular twins had the abnormality (Crosby 1953) The onset is usually in adult life, the sexes are equally affected It has been suggested that the disease is due to some unknown sensitisation Experiment has failed to reveal any abnormality in the hæmoglobin (McIlvaine and Beard 1951 and our own results) The apparently normal condition of plasma and hæmoglobin in this disease points to the red-cell envelope as the seat of the abnormality Despite the claim by Matthes et al (1951) to have demonstrated lacunæ and a mesh like appearance in electron microphotographs of P N H cells, our findings showed no significant difference between P N H and normal cells Sundharagiati and Wright (1953) found changes similar to those described by Matthes et al in a variety of blood dyscrasias and believe that these were due to artefacts

Splenectomy has been found to be useless or even harmful Treatment with alkali is ineffective (Buell and Mettier 1940), and numerous hormones and drugs have been tried without success by other workers Crosby (1953) showed that dicoumarin may help Thrombin destroys the normal heat stable inhibitor of lysis By preventing conversion of prothrombin to thrombin dicoumarin inhibits this destruction In emergency, transfusion with homologous cells washed free from plasma is effective

Summary

A case of paroxysmal nocturnal hæmoglobinuria is described

The laboratory findings were characteristic Some hæmolysis was present even when there was clinical remission Electrophoretic examination of the hæmoglobin revealed no abnormality Electron microscopy of the lysed red blood-cells showed no difference between their envelopes and those of normal erythrocytes

We wish to thank Miss H. M Laird, of the Beatson Memorial Hospital, f [illegible]eparing and reporting on the electron micro photographs, Dr J Wallace, of the West of Scotland Bl Transfusion Service, for serological examination of the bloo and Dr David Smith, of Glasgow Royal Infirmary, permission to examine the patient

ON THE SEX OF CANCER AND TERATOMATA CELLS

AMÂNDIO S TAVARES
M B Oporto
ASSISTANT, DEPARTMENTS OF GENERAL AND ANATOMICAL PATHOLOGY, FACULTY OF MEDICINE, OPORTO UNIVERSITY, PORTUGAL

A MORPHOLOGICAL sexual difference in the nucle nerve-cells of cats was found by Barr and Bertr (1949, 1951), and later work showed that a chromat mass called "sexual chromatin" or "corpuscle of Barr is seen in about 75% of nuclei of various tissues in femal but is seldom detected in males (Barr et al 1950, Grah and Barr 1952)

These findings have been applied to the diagnosis sex in other animals and in man (Moore and Barr 195 For instance, nuclear sex has been studied by th method in transvestites (Barr and Hobbs 1954), herm phrodites (Moore et al 1953, Barr 1954), and Turne syndrome (Polani et al 1954) Using a slightly modifi technique, Emery and McMillan (1954) say that, exce for some doubtful results obtained in necropsy mater in the newborn, the method is reliable when applied children

Hunter and Lennox (1954), who examined spin cellular epitheliomata of the skin, conclude that canc cells are of the same sex as the patient, but, as regar teratomata, 5 out of 9 in males were heterosexu whereas 12 teratomata in women were all of the sam sex as the patient If this latter finding is applicab generally, we will have to revise our ideas of the genes of teratomata

Meanwhile we add to the findings of Hunter an Lennox (1954) and of Cruickshank (1955) our finding in 34 teratomata and 110 cancers

Method

We used formalin fixed paraffin embedded section 5–8 μ thick stained with hæmatoxylin and eosin, and

TABLE I—SEX OF CANCER CELLS

Tumour	Sex of patient					
	Male			Female		
	Average (%)	no of cases	Range (%)	Average (%)	no of cases	Rang (%)
Carcinoma of skin	5 9	24	1 5–17 0	72 9	27	[illegible]
Undifferentiated carcinoma of skin		2	1 0– 4 0		3	[illegible]
Primary carcinoma of liver		1	11 5		3	[illegible]
Adenocarcinoma of stomach	5 6	5	2 5– 9 5	69 8	5	[illegible]
Papillary carcinoma of bladder	6 4	5	3 0–12 0	70 2	5	[illegible]

Seminoma of testis	4 0	5	3 0– 5 5			
Carcinoma of kidney	7 5	5	4 0–11 0	71 9	5	[illegible]
Myosarcoma	8 6	8	5 5–15 0		2	[illegible]

TABLE II—SEX OF TERATOMA CELLS

Sex of patient	Sex of teratoma cells							
	Male				Female			
	Hunter and Lennox (1954)	Cruickshank (1955)	Present investigation	Total	Hunter and Lennox (1954)	Cruickshank (1955)	Present investigation	Total
F					12	2	25	39
M	4	2	5	11	5	1	4	10
Total	4	2	5	11	17	3	29	19

χ^2 (for 1 : 2 ratio) = 1·999 P = 0·166
χ^2 (for 1 : 1 ratio) = 0·0476 P = 0·962

controls were stained by the Feulgen method We found fixation to be of greater importance than the method of staining

Counts were made of nuclei containing the sexual chromatin, as defined by Barr and his colleagues, and percentages were established for at least 200 cells doubtful nuclei were counted as half positive half negative Immature and degenerated cells were excluded and only one nucleus was examined in the multinucleated elements so commonly found in cancer

This method gave statistically significant results ($P = 1 \times 10^{-11}$) with a relatively small standard deviation ($s = 2·5$) In the case of normal skin cells of 40 adults the sexes being well separated (females 60–80% males 1–18%) and the two frequency curves showing diverging skewness.

Results

Cancer

In 110 sundry malignant tumours, taken at random for each variety from the cases registered in the department of anatomical pathology in the University of Oporto the sex of the patient and that of the tumour were the same (table I) The range of results shows no significant difference between normal and cancer cells and identical percentages were obtained when both were examined in the same section Neither localisation nor type of neoplasm influenced its 'sex' the only exceptions were two undifferentiated carcinomata of the skin in women the low figures (27% and 55·5%) may be explained by the immaturity of the nuclei in these neoplasms.

The number of chromatin containing cancer cells and mature histiocytes in the stroma of the tumour were counted in 20 cases and differed very little ($t = 0·632$ d f. = 10) The histiocytes proved much more reliable than epithelium because in the undifferentiated carcinomata mentioned above the histiocyte-counts were 70·0% and 74·5%

Teratomata

Our findings in 34 teratomata (25 from women and 9 from men) were very similar to those of Hunter and Lennox (1954) all 25 from women were 'feminine' whereas 4 of the 9 from men were 'masculine' If we combine our findings with those of Hunter and Lennox (1954) and Cruickshank (1955) we find that 48% of teratomata in males are heterosexual This fact argues against two current theories of the genesis of teratomata: the blastomere theory and that of parthenogenetic division of a diploid cell On the other hand not much support is lent to the theory of gamete (or at least haploid cell) conjugation proposed by Hunter and Lennox (1954) which calls for a ratio of 1 XX : 2 XY : 1 YY teratomata According to Moore and Barr (1954) only the pair of XX chromosomes determine the appearance of sexual chromatin This reduces the genetic ratio to 1 XX : 3 (XY + YY) or if YY cells do not survive (and we know very little on this subject) to 1 XX : 2 XY The χ^2 test of departure gives a probability rather close to the statistical level of significance (table II)

The objection that teratomatous material, since it is often either undifferentiated or immature is unsuitable for this study does not hold at least for our series only nuclei from mature epithelial connective and nervous tissue were counted On the other hand, if lack of cell differentiation (which may only cause a depression in percentages as we have shown) influenced our results, these would be reversed and heterosexuality would be found in women alone

A far greater number of teratomata will have to be studied before any theory emerges from these findings However, one explanation of a 1 : 1 ratio is perhaps, the parthenogenetic division of haploid cells followed by chromosome reduplication, forming 100% of XX cells in the female, and 50% of XX and 50% of YY cells in the male Of course this means attributing a pair of YY chromosomes to the cells of some teratomata, and we do not know anything about their viability

LOCAL TRANSMETATARSAL AMPUTATION IN ARTERIAL INSUFFICIENCY OF THE LOWER LIMB

A. G NORMAN

M.A., M B Camb F.R C.S

SENIOR SURGICAL REGISTRAR, ST THOMAS'S HOSPITAL, LONDON

ARTERIAL insufficiency of the lower limb is nowadays treated more conservatively than formerly preserving as much of the limb as is compatible with healing and sound function In gangrene of the foot amputation at the metatarso phalangeal joint commonly proves unsatisfactory and in the past these unsuccessful cases were treated by high amputation We now attempt to save more limbs by local transmetathrsal (ray) amputation

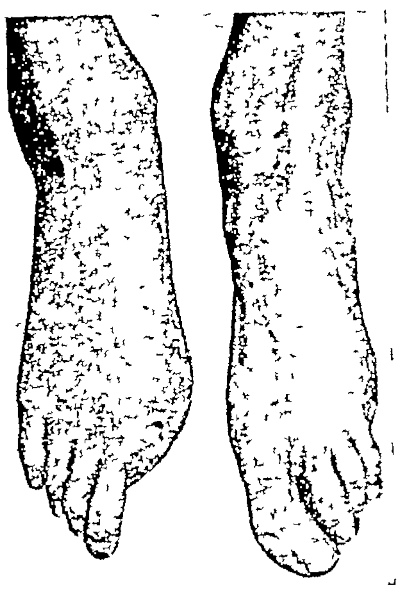
In the present series of 12 cases involving 14 limbs with gangrene of toes only one of the five toes was involved in 10 limbs This suggests that there must be some *local fault in the circulation of the affected toe* Our arteriographic studies have led us to believe that gangrene in the arteriosclerotic patient results from multiple blocks and we suspect that in these cases the final block is in the plantar metatarsal arteries as they pass the head of the metatarsal bones (Rob 1954) Although the *toes, unlike the fingers* have both dorsal and plantar digital arteries it is the plantar arteries that carry *most of the blood supply*

In local transmetatarsal amputation the toe and the head of the corresponding metatarsal bone are removed through an anterior racket incision The aim is to amputate above the level of the arterial block Great care must be taken to clear away all splinters of bone since these if unremoved, delay healing

Of the 12 patients (9 men 3 women) whose average age was 61·5 all had diffuse arterial disease and 5 were diabetic The main manifestations in the 14 affected limbs were: dry gangrene (6 cases) ulceration (5), and cold blue toe (3), and the average length of history was four months In 5 cases these manifestations had been preceded by claudication in the calf

The digits most commonly affected were the first, fourth, and fifth The numbers affected in the 14 limbs were first digit, 4, second digit, 1, third digit, 1, fourth digit, 7, and fifth digit, 5

The results at three to fifteen months after operation were as follows healed, 7 (primary healing 5, delayed healing 2), unhealed, 2, required high amputation, 5 Thus the failure rate was 36%, which is similar to the 37% in a series of total transmetatarsal amputations described by Warren et al (1952)



Foot after local transmetatarsal amputation of right first toe and left fifth toe

Analysis does not reveal any sign by which failure can be predicted Failure was unrelated to age, sex, or the presence of diabetes

This operation is designed to remove as little as possible of the gangrenous limb McKittrick (1946), McKittrick and Risley (1949), Furste and Herrmann (1948), and others have attempted to achieve this end by total transmetatarsal amputation, thereafter the foot functions well (unlike the state after amputations at the tarsus by the method of Lisfranc and Chopart), and their results are similar to those described here

After local transmetatarsal amputation the healed foot (see figure) is functionally satisfactory, and the limited follow up in the series described here shows that the wound remains satisfactorily healed In 1 of the diabetic patients a perforating ulcer of the foot developed, but the amputation site remained healed

I am indebted to Prof George Perkins for introducing me to this operation, to Mr F B Cockett for criticism and advice, to the physicians and surgeons of St Thomas's Hospital for permission to describe their cases, and to Mr K G Moreman for the photograph.

Medical Societies

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE 54th meeting of this association was held in Douglas, Isle of Man, on April 13–15 We publish summaries of some of the papers presented at the meeting

Typing in Epidemiological Investigations

Dr W H **BRADLEY** said that Griffith had first introduced serological typing of hæmolytic streptococci in 1926, and by 1934 a range of 27 reference types was available Craigie and Felix had shown in 1938 that bacteriophage typing of *Salmonella typhi* was practicable, and by 1947 they had prepared a couple of dozen reference phages The significant fall in the mortality of streptococcal disease (particularly puerperal sepsis) between 1934 and the advent of sulphonamides probably reflected the increase in the possibility of outbreak control stimulated by the Griffith's typing

The mortality of enteric fever in the United Kingdom had fallen away more rapidly than in other European countries, and this improvement coincided with the introduction of phage-typing Dr Bradley thought that because typing made epidemiological investigations more convincing and more fun their quality was improved and preventive medicine became more effective Moreover, epidemiological and ætiological concepts had been reshaped The rôle of type 12 and to a lesser extent type 4 streptococci in nephritis was an example It was now realised that the many distinct serological or phage types within a species were acting independently and that their specificity was enduring

Antigenicity of Toxoids and Sympathomimetic Drugs

Dr J **UNGAR** described how water insoluble mineral carriers such as aluminium or calcium salts, tapioca, oils and fats, and, recently, bacterial suspensions, had been used to increase the efficiency of prophylactic toxoids and thereby reduce the number of injections required Their presence caused local irritation, which was most severe with aluminium and calcium salts and least severe with bacterial suspensions, he had used *Hæmophilus pertussis* vaccines successfully in the past

As the use of vaccines might be undesirable in hypersensitive persons, Dr Ungar had tried to improve the antigenic efficiency of diphtheria toxoid by altering the rate of absorption with drugs exerting a local tissue effect Adrenaline hydrochloride (1 in 1000 to 1 in 2000), benzedrine hydrochloride (1 in 250), ephedrine hydrochloride (1 in 250), and histamine (0 5 µg per ml) had been used Two amines, β phenylethylamine and phenylethylamine acetate, which have no vasoconstrictor action, were included as controls When tested in guineapigs the sympathomimetic vasoconstrictors greatly enhanced the response to diphtheria toxoid Combination with histamine caused only slight enhancement and the two control amines did not affect the response to the toxoid Vasoconstrictors might prove useful for enhancing the efficiency of diphtheria toxoid, especially when children hypersensitive to injections of antigen were being immunised

Lung Carcinoma in Hæmatite Miners

Dr J **STEVEN FAULDS** said that the incidence of primary cancer of the lung in iron ore miners in Cumberland over the last twenty three years was 9 4%—four times that found in a control group of males of similar age and habits, but different occupation. The site of the tumours corresponded to the areas where the characteristic massive fibrosis developed, and the primary lesion was not in the main bronchus, but in a peripheral lung field The observed association of squamous celled lining to a chronic abscess cavity and a squamous carcinoma in the same area suggested that the tumour arose in the sidero silicotic mass Since silicosis was a frequent finding in other kinds of mining and an association between silicosis and bronchial cancer was not common, it was difficult to give a reason for the increased frequency of carcinoma found in iron ore miners

Lower-nephron Nephrosis

Dr S **SEVITT** showed that distal tubular necrosis (lower nephron nephrosis) in the kidneys of burned patients was commoner among those who had an adequate or normal flow of urine than in those with severe oliguria or anuria Clinically and biochemically there were uræmic and non uræmic forms with little or no oliguria The uræmic group was important to diagnose because the recent advances in therapy may reduce its high fatality Morphologically these kidneys showed a *diffuse* distal tubular neurosis in which hæmoglobin casts were prominent Many nephrons were involved and although the morphology was no different from that found in those with anuria or severe oliguria, tubular function was impaired

The finding of non-oliguric uræmia in an injured man with histological distal tubular necrosis of the kidneys indicated that the phenomenon was not restricted to burned subjects In the non uræmic condition there was no significant azotæmia during the illness, and death was due to non renal complications. Histologically the kidneys of these patients should show either a *focal* type of distal tubular necrosis, associated with few casts and affecting only a minority of the nephrons, or the healing or healed evidence of a recent focal attack.

Blood-ammonia Levels in Liver Disease

Mr A G Riddell described experiments on dogs with portacaval anastomoses which had shown that a neurological disorder can be produced in these animals by intoxication with ammonia Histological examination of the brains of these dogs showed the same change in the protoplasmic astrocytes as in patients dying in hepatic coma In hepatic coma a raised blood ammonia level was found The type of hepatic coma that followed bleeding from œsophageal varices was analogous to the syndrome seen in dogs and the ammonia was derived from the blood in the alimentary tract While blood ammonia determinations were required in the diagnosis and management of unusual cases, they were not required in the routine treatment of hepatic coma.

Fibrinous Vasculosis

Dr A. C Lendrum suggested this term for the deposition in blood vessel walls of a material giving the staining reactions of fibrin. The commonest cause of this was severe stagnant ischæmia, as in infarction or torsion Other causes were drug-induced hyperergic arteritis extreme hypertension, polyarteritis nodosa and occasionally acute rheumatic disease disseminated lupus erythematosus and dermatomyositis The fibrin was commonly seen under an intact endothelium sometimes as a complete ring round the intima From this level it either seeped into the wall (vessels of infarcted zone) or was injected across the media (in extreme hypertension) to spread out along the external elastica through which it may erupt focally At sites where a layer was traversed, there was in all types of fibrinous vasculosis a stretching and distortion of the nuclei as if they had been subjected to mechanical extension. Gross cellular aggregation was seen in and around a few some or all of the affected vessels. Intravascular thrombosis was uncommon except in small vessels, even when the vessel wall was a mass of fibrin

The most extreme degree of fibrinous vasculosis had been seen in the pulmonary vessels in 2 cases of mitral stenosis; and the next degree in infarcted organs. The three forms of fibrinous vasculosis, the stagnant hypertensive and hyperergic, appeared to be histologically indistinguishable. All might be regarded as a form of exudation due to an upset between the pressure in the vessel and the permeability of the lining

Hæmophilia and Christmas Disease

Dr Rosemary Biggs discussing the diagnosis of these conditions, said that the laboratory tests of clotting function that have been used were the whole blood clotting time the prothrombin-consumption test and the thromboplastin generation test. In hæmophilia the clotting time was prolonged in more than half of the patients, but patients who are quite severely affected may have a normal clotting time Similarly the prothrombin-consumption test usually gave abnormal results in hæmophilia, but with some samples results were normal The thromboplastin-generation test gave more reliable results in hæmophilia blood than either of the other tests, and using this technique it was possible to distinguish patients with hæmophilia from those with Christmas disease About 10% of patients previously diagnosed as having hæmophilia were found to have Christmas disease Of the patients with Christmas disease many were rather mildly affected with a normal clotting time and consumption of prothrombin

Interstitial Emphysema in the Newborn

Dr John L. Emery in a consecutive series of 100 infants dying within seven days of birth had found that 7 out of 5[illegible] full term children had died with interstitial emphysema After congenital deformities it was the commonest single cause of death The condition was spontaneous and not due to artificial respiration it was probably caused by the expulsive efforts of crying in lusty infants who had inhaled vernix or mucus.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM

Diamox in the Treatment of Glaucoma

The 75th congress of the Ophthalmological Society of the United Kingdom, held in London on April 28–30 included a symposium on Diamox' in the Treatment of Glaucoma Diamox (2-acetylamino 1 3 4 thiadiazole 5 sulphonamide) has been known for some years to have a powerful inhibitory effect on the enzyme carbonic anhydrase and it has been used in the treatment of congestive heart-failure because of its diuretic effect [1]

Mr E S Perkins analysed the results in 58 cases treated at Moorfields Eye Hospital, and confirmed the value of this drug in controlling all of the major categories of glaucoma in about 50% of all cases—congestive glaucoma, simple glaucoma and glaucoma secondary to iritis and to trauma—the tension was brought well under control while of the remaining cases about half were controlled partially or for a short period This effect was potentiated by the simultaneous use of miotics The dosage suggested was 500 mg initially followed by 250 mg six hourly after a few days this dose could generally be reduced to twice or thrice daily at which level it should be maintained Side-effects were rarely disturbing diuresis and paræsthesiæ were usually very transient Mr Perkins concluded that the particular value of diamox was in the control of acute congestive glaucomatous crises where it allowed the eye to quieten for a subsequent drainage operation; in certain cases of simple glaucoma where miotics had failed to achieve effective control, and in cases of iritis glaucoma in which the tension could be controlled until the initiating iritis had been allayed

Dr John Gloster described his estimation of the effect of diamox on the intra-ocular pressure of normal rabbit eyes. He found that an intravenous injection of diamox caused a drop in the intra-ocular pressure within one minute the speed of this action suggested that it was due to a direct effect on the secretion of aqueous humour in the ciliary body The changes estimated by the insertion of a cannula into the aqueous, were significant only with doses larger than those used clinically

Dr Maurice Langham reported the results of further experiments on rabbit eyes Observations were made first on the effect of diamox on the distribution of bicarbonate between the aqueous humour and the plasma, since it might be assumed that the inhibition of the production of hydroxyl ions would decrease the osmotic pressure of the aqueous and thereby reduce its formation The influence of the drug was assessed according to the permeability of the blood aqueous barrier and the flow of the aqueous humour by measuring the rate of accumulation of fluorescein in the aqueous humour after intravenous administration It was found that although the bicarbonate in the aqueous diminished after the administration of diamox its concentration relative to that in the plasma was unchanged The method by which diamox reduced the formation of the aqueous thus remained uncertain; the results of his experiments did not show whether diamox in fact exerted its effect by its systemic action or through a non specific inhibition of aqueous secretion

Prof G P Sourdille (Nantes) reported clinical observations which agreed essentially with those described by Mr Perkins

Reviews of Books

Practical Obstetric Problems

IAN DONALD, M B E , M D Lond , M R C O G , regius professor of midwifery, University of Glasgow London Lloyd-Luke 1955 Pp 578 45s

IN many ways this is an admirable book, but it is not addressed consistently to any particular group of readers, and one cannot easily say just what kind of book it is. The title and part of Professor Donald's preface suggest that it is largely a reference work for the practising obstetrician, but, though the practising obstetrician will find much profit and enjoyment in its discussion of controversial problems, it leaves out things one would expect it to contain It is not a textbook, for the anatomical and physiological ground-work of obstetrics has been deliberately omitted Perhaps it will be of most value to those who have a little experience of obstetrics and are sitting a higher examination —though these will have no need of the details of simple obstetrical procedures (such as toilet of the vulva before forceps delivery) nor of some of the discussions of matters that belong to undergraduate rather than postgraduate teaching

The points at which fellow experts will take issue with the author mostly concern manipulative obstetrics In the section on manual correction of the fœtal head in the occipito posterior position, a good method is described for altering the fœtal position, but no reference is made to the alternative techniques, such as rotating the shoulders by the internal hand or correcting the malposition by placing the hand over the fœtal face In the section on breech delivery the description of the rotation of the anterior shoulder posteriorly does not mention the desirability of over correction if the back of the fœtal head is to remain directed to the symphysis The statement that "the lateral position for forceps delivery has been abandoned" takes no account of those who are convinced that the lateral position confers at least the two advantages of a reduced risk of anæsthesia and less perineal damage Some, too, will disagree with the opinion (on twins) that "if a general anæsthetic has been necessary in the course of delivery of the first child it is usually preferable to discontinue it while awaiting the arrival of the second." Sweeping statements such as "Cæsarean myomectomy is an indefensible operation" and "undoubtedly" routine X ray pelvimetry in all primigravidæ "will come in time" belong perhaps to the cut and thrust of debate rather than to the printed page

Against these objections must be set the important fact that the book conveys much of the author's zest Some of its parts, and some of its sentences, are too long, but it is often very readable Many will be grateful for its robust, uncompromising approach, and above all for its stimulating enthusiasm

Memoirs of My Nervous Illness

DANIEL PAUL SCHREBER Translators and editors IDA MACALPINE, M.D , RICHARD A HUNTER, M.D , M.R C P , D.P M London Wm Dawson 1955 Pp 416 £1 15s

AUTOBIOGRAPHICAL accounts of mental illness are valuable documents, especially when written by patients of high intelligence, gifted with powers of self-observation and accurate recollection These qualities were undoubtedly possessed by Daniel Schreber, a judge of the supreme court in Saxony, who developed a severe schizophrenic illness in late middle life His account of his experiences in this illness, first published in 1903, was the subject of a study by Freud eight years later Freud's paper has become important in the development of psycho-analytic theory about psychoses, and the Schreber memoirs are often mentioned, but usually by people who have not read them, because the book has become scarce and has never been translated from German Dr Macalpine and Dr Hunter have now made good this deficiency

Their translation does not always run smoothly, but it may well be a faithful reproduction of Dr Schreber's style Schizophrenics do not write with terse and graceful precision, nor perhaps do judges, and the reader is willing to accept the translators' disconsolate reference to Schreber's cumbersome and involved language They give examples of his neologisms in an appendix They have fallen into a few well known traps—such as translating *Moment* as "moment" instead of "factor"—but these are trifling blemishes in a large undertaking Besides the memoirs, the book contains a clinical and historical introduction by Dr Macalpine and Dr Hunter, a reprint of their informative psychopathological article on the Schreber material, and translations of the psychiatric reports on Schreber, the legal statement in which he asked to be given back control over his affairs, and the judgment of the court which heard this appeal.

The translators ride a few hobby-horses, as their incidental polemic against physical forms of treatment shows, but the grateful reader will not begrudge them this by-product of their labours for his benefit, he may even, unless an orthodox psycho-analyst, find their irreverent re-examination of some central issues of Freudian psychopathology stimulating

Examen clinique et traitement d'un endocrinien

A. LICHTWITZ and R PARLIER, Hôpital Lariboisière Paris Paris L'Expansion scientifique française 1954 Vol I Pp 456 Fr 5200 Vol II Pp 302 Fr 4800

To apply recent advances in endocrinology demands some understanding of the experimental techniques which produced them Doctors are often ill equipped by their training to follow the methods of diagnosis and treatment that have evolved Dr Lichtwitz and Dr Parlier, in this frankly didactic account of endocrinology in its modern setting, have, by their attention to layout, tables, and diagrams, done much to explain the scientist's findings to the clinician In the preface they write "We hope the jealous guardians of pure biological science will pardon certain abuses of simplification, remembering that our aim is to reach not only those doctors who wish to perfect their knowledge of modern endocrinology, but all those who are harassed by the problems of general pathology" But the questioning and thoughtful reader may be disappointed

Dr Lichtwitz and Dr Parlier deal first with some general principles and then with the hypophysis, the thyroid, the ovary, and, in the second volume, with the testes and the suprarenal Throughout, the influence of Selye makes itself strongly felt The book is a useful guide to the French literature and in particular to the authors many original articles. It is lavishly produced, and misprints are mostly in the references but the index is unfortunately sketchy

The Challenge of Man's Future

HARRISON BROWN London Secker & Warburg 1954 Pp 290 21s

Prof Harrison Brown is a chemist with an expert's knowledge of the earth's material resources, an American's optimism about human capacity, and a citizen of the world's awareness of the rake's progress and the fateful hour Like Sir Charles Darwin he sees the ultimate consequence of an uncontrolled growth of population and a spendthrift use of our resources, but he is not convinced that there is no escape from this doom

He foresees three possible patterns of life reversion to the agrarian existence of the pre-industrial period a completely controlled, collectivised industrial society in which war has been abolished, new energy sources are utilised, and population is kept stable, a world wide free industrial society, labile but capable of permanence The last, the most desirable and to our favoured Western minds the expected outcome of "progress," is the most difficult to achieve since it requires efforts beyond anything human beings have so far compassed They must adapt themselves to constant change, preserve freedom while accepting control of reproduction, aggression, and other old desires, and use their intelligence and self-restraint now in order to conserve their dwindling extra-human resources and so turn to most use their inner resources of wisdom and generosity Though this is the conclusion of the matter, and gives only chastening comfort, it follows a well-organised factual account of what is happening and what must later happen if we continue in our present courses the account is objective and the main argument irrefutable

THE LANCET

LONDON SATURDAY, MAY 7, 1955

Research in General Practice

> There is a danger inherent in the work of general practice that the very great variety of subjects for practice and thought in a day's work may lead to a superficial and desultory curiosity rather than an eagerness for study.

WHEN he offered this reflection in the first John Matheson Shaw lecture[1] of the Royal College of Physicians of Edinburgh last November, Prof. JAMES MACKINTOSH was discussing the opportunities for research now opening before general practitioners. A Sassenach might have softened the blow with some reference to the fatigues of the family doctor's day, but Professor MACKINTOSH merely added that "it is easy to spread a thin layer of butter on the bread of idleness." This bracing approach has much to commend it, for some of the past attempts to get general practitioners to contribute to research have started hopefully but died of inanition. Too often self-chosen projects lose their charm for men working in isolation, especially during winter epidemics. Modern research is often done best by a team, and the College of General Practitioners[2] is surely right in encouraging group projects while at the same time offering information and help to the investigator who prefers to work alone.

At the end of 1954, the register of members willing to take part in research maintained by the research committee of the college council, contained some 380 names, sent in from every part of the Commonwealth. Research committees of 22 faculty boards have been formed in the British Isles and overseas composed of members and associates of the college and also coöpted members from local university or medical-school research departments. The college research advisory panel composed of experts in various medical fields, has been strengthened during the year. Scotland has its own research committee of the Scottish council with its own research advisory panel.

Four types of general practitioner research are being forwarded: college-sponsored investigations, studies by groups of doctors, faculty sponsored investigations, and individual investigations. The college sponsored investigations deal with subjects which can be studied only in general practice, or studied there better than in hospitals or laboratories.

A measles investigation to assess the value of sulphonamides and antibiotics in preventing complications is already in progress, and has only been handicapped (the report remarks sadly) by the low incidence of measles in 1954. Better things are expected of 1955 and a report may be published by the end of the year. A national morbidity survey is being planned in collaboration with the Registrar-General's department; and a college records unit is being set up which should enable morbidity statistics to be recorded in a comparable way throughout the United Kingdom and overseas. Discussions with the Ministry of Health have resulted in the release of National Health Service records of dead patients to doctors needing them for research purposes. It has been suggested that clinical trials of therapeutic substances might be made by general practitioners, but this introduces some ethical problems to which the college is rightly giving serious thought. Finally the epidemic observation unit of the college has coöperated with the Public Health Laboratory Service in collecting specimens from suspected cases of influenza for identification of the virus. Through this unit one member of the college has already brought to light an outbreak of Q fever in the South West; and specimens from a recent outbreak of infective hepatitis in the South East have been collected and studied.

Among the study-groups, one is engaged in observing the clinical patterns of acute respiratory infections; another, interested in hereditary diseases, is examining the incidence of hypertrophic pyloric stenosis in the children of people who have themselves survived Rammstedt's operation; a third group is investigating the value of tonsillectomy; a fourth interested in psychosomatic disorders, is making a study of asthma and migraine; and a fifth small group is concerned with *asthma in children*.

Faculty-sponsored investigations include one into obstetrical work in South West England; a study of the symmetry of heads of babies in Northern Ireland to determine whether cranial asymmetry is related to right handedness or left-handedness; a study, in Yorkshire, of the course of cancer in patients who for one reason or another have not been treated; and an epidemiological survey in South East England of non-notifiable diseases including glandular fever, infective hepatitis, and epidemic winter vomiting.

These studies have been started with great enthusiasm but the college has it in mind, from the history of earlier collective investigations, that too great a dispersal of effort may lead to disappointment, and moreover (Professor MACKINTOSH notwithstanding) that there is a limit to the amount of voluntary work a family doctor can undertake over and above his practice. They are therefore wisely planning rather to consolidate the research work begun than to expand into new fields during the coming year.

It is interesting to compare this promising beginning with the research programme Professor MACKINTOSH foresees for general practitioners in years to come. The Public Health Laboratory Service, as he points out, has greatly added to their powers to contribute to systematic research; and he hopes that before long a more organised system of diagnostic centres will be developed and take the place of the health centres —"which are now by general consent slipping back into the waters of Lethe." These, like the Nuffield diagnostic centre at Corby,[3] would be staffed by technicians working under the supervision of specialists, and here general practitioners would have direct access to technical help in the more straightforward types of bacteriology, radiology, and pathology—or could, if they wished, undertake laboratory procedures themselves.

First in his list of possible studies Professor MACKINTOSH puts hereditary defects and diseases, for family doctors, and especially old established firms of doctors, have a better chance than most of noticing what happens from generation to generation. They can assess the significance of the eccentric relative and the slow child; can turn up records of stillbirths, neonatal deaths, minor congenital abnormalities, hæmophilia, Huntington's chorea, and pyloric stenosis; can observe the effects of common complaints on patients and their environment; and can assess the long-term effects of remedies old and new, and the protective value of vaccines. They alone have the chance of seeing the onset and full course of the diseases associated with old age, and can investigate both the basic and the precipitating causes of the so-called stress diseases They have remarkable opportunities, of which many of them make full use, of gaining skill in prognosis , and many a young doctor joining an old firm is startled out of his scientific calm by the uncanny skill of the senior partner in predicting the immediate and remote outcome of disease As Professor **MACKINTOSH** says, the true effects of pregnancy on chronic disease are largely unknown at specialist level Again, though the gross pathology of established disease can be seen and learned in hospital, the delicate innuendos of early disorder are to be apprehended only in general practice They are learned by watching the same patients for a lifetime Mental sickness, which sometimes has its origins in human relations, gives the general practitioner another field for study "The observation of years in a mental hospital or psychiatric clinic may not reveal as much about such *patients in their true* environment as the general practitioner learns in the course of his daily plodding ", and he it is, at present, who undertakes most of the follow-up and aftercare of patients who have been treated in mental hospitals Epidemiology still has many questions to be answered some incubation periods are still uncertain, and the modes of spread of many diseases are far from clear Professor **MACKINTOSH** notes the work in this field already being undertaken by the college, but mentions other possible inquiries—not only into the well-known infections such as chickenpox, herpes zoster, and *poliomyelitis, but into local non-infectious diseases* such as goitre and dental caries , and into chronic disorders such as rheumatism and bronchitis Finally, he suggests there is plenty still to study in the field of normal health and physiology—the disturbances of puberty and the menopause, the male climacteric, the onset of presbyopia, the significance of bodily and emotional types, and "the long fascinating story of child development "

[3] *Lancet* 1954 i 871

So much for the programme but there are, he hints, obstacles The first is the medical curriculum, which not only fails to prepare the student for research under the conditions of medical practice but introduces him mainly to the late stages of disease, gives him the scantiest notions of the relations of sickness to social and industrial life, and does not equip him with enough elementary statistics to conduct simple investigations in the field of general practice Given an early understanding of statistical methods and of the importance of controls he would quickly recognise how little is other apparatus needed for important work two eyes, a pen, and a record card often suffice Other obstacles are the want of liaison between general practitioners and consultants, the scarcity of leisure, the broken time, the prejudice of patients ("people in general have a respect almost amounting to awe for research, but they do not enjoy being the subjects of investigation themselves "), and the absence of a stimulating atmosphere, such as is found in hospital or laboratory But all these obstacles, he urges, can be overcome The college is already playing its proper part by giving help and guidance (particularly in the matter of collecting accurate statistics), by organising research teams and groups, and by keeping keen people [illegible] with one another and with experts in their subjects . Other incentives must come from elsewhere—from the medical schools, which must equip their students better for research , from the Ministry of Health, which can distribute information about minor disorders (bronchitis, common colds, and the neuroses) which are responsible for much ill health, and as a by-product from group practice which gives the doctor time for reading, writing attending *clinical meetings, looking* after his own health , and developing more fully his skill in his profession

Cell Type in Bronchial Carcinoma

NO-ONE would suggest that surgery is an adequate weapon in the treatment of bronchial carcinoma, but it is the best we have , and with modern technique roughly one quarter to one third of patients who have "*curative*" resections survive operation by at least five years $^{1-6}$ *It* is now clear that the prognosis in these cases is greatly influenced by the cell type of the tumour $^{5-8}$ Bronchial carcinoma is usually classified histologically as squamous cell, adenocarcinoma, or undifferentiated , but **KIRKLIN** et al ^{6} consider that it is worth subdividing the undifferentiated group into *small cell* carcinoma and large cell *carcinoma* The *cells in small cell carcinoma* have little cytoplasm, *they are irregularly arranged,* and as the nuclei are often spindle shaped the term "oat cell " is commonly applied to this group The cells in **KIRKLIN**'s large-cell type have more cytoplasm, but the other histological features are variable, sometimes resembling those of the small cell variety *and sometimes those of the squamous cell type,* so *that pathologists recognising only three groups* would put them in one or other of these categories

The prognosis in the small-cell (oat-cell) type is very poor, though occasional good results are achieved On the other hand, the outlook in the squamous cell variety is relatively good $^{5-8}$ There is more doubt about the prospects with an adenocarcinoma, **KIRKLIN** and his colleagues,[6] for example, consider that the chances of a successful operation are almost as good as with a squamous cell tumour, whereas **HOLMES SELLORS**'s experience ^{5} has been that the chances are not much better than in the deadly small cell group The prognosis in the large cell variety is poor, though *it* is apparently *somewhat* better than when the tumour is of the small cell type [4] Moreover, squamous-cell carcinoma means more than a better chance of survival after a "curative" operation, for a higher proportion of such growths are amenable to surgery when first diagnosed $^{6\ 8}$, so that at first sight it seems fortunate that in most analyses of the results of treatment in bronchial carcinoma this variety is commonest But, as **BIGNALL** has lately pointed out,[9] it is the highly malignant small cell

tumour which preponderates in necropsy studies, and this discrepancy may be explained by the fact that it is the potentially operable cases which go to the special centres from which statistics of survival rates usually come

It is difficult to get reliable information about the actual proportion of all cases which are suitable for surgery when first diagnosed but it is safe to say that it is depressingly low Can the position be improved? Nothing can be done about the most decisive factor influencing survival—the cell type of the tumour—but there is a chance to reduce the delay between the appearance of symptoms and diagnosis Even so, it is doubtful whether any sizeable improvement in the situation would follow and experience so far suggests that mass radiography [9,10] has no striking contribution to make towards a reduction in mortality Indeed BIGNALL came to the sombre conclusion that, even with the most efficient medical service possible we could not, with present methods of diagnosis and treatment hope for any substantial improvement He suggests that we should aim at more effective palliative remedies and it is only necessary to consider the vast sum of human suffering involved to appreciate the value of any such advances

A Century of Army Pathology

THE story of pathology in the Army is one of small beginnings, big opportunities distinguished achievements, and heavy responsibilities faithfully discharged At the centenary of the service last week there was no lack of great names to honour or fine work to recall but above all there was a sense of this work continuing Nor is it limited or separate from work elsewhere Nowhere more than in pathology is there interchange between Army and civilian medicine, and the mixed gathering at the Royal Army Medical Corps Headquarter Mess on April 27 was evidence of a symbiosis which has been particularly happy and always beneficial

The day was chosen because it was on April 27 1855 that Dr R S D LYONS, an Irish physician, and his "two able assistants" Dr WILLIAM AITKEN and Dr DOYLE, were sent their instructions on the pathological researches they were to undertake at Scutari among the sick and wounded of the Crimea In his centenary article on the service Major-General SACHS [11] quotes these instructions

> 4 As Morbid Anatomy is of little value unless studied in connection with the history of the disease you and your Assistants will require to visit the Hospital wards in order to become acquainted with the symptoms and characters of the diseases during their progress but you will not interfere with the treatment of the patients. In making notes of the cases, the name of the patient, and the number of his regiment should always be stated as by this means the nature of his duties, and the place where he was first attacked by disease can be more easily ascertained
>
> 6 It is expected that you will not content yourself with the simple dissection of the subject and the demonstration of the morbid parts, but that you will submit them to microscopical examination

Even at this early date in an era when little was known about the staining of tissues the importance of the microscope is usefully emphasised, and the instructions are well drawn. Less understanding was shown by the War Office when for years it blocked the plans made by FLORENCE NIGHTINGALE for a school of military hygiene and when at last, in August, 1860, the Practical Army Medical School was opened at Chatham the first 10 students found bare walls and no equipment Nevertheless it was not long before the school as the Army Medical College at Netley, redeemed its bad start Its professor of pathology from 1860 to 1892, Sir WILLIAM AITKEN F.R.S., became the father of military pathology and was to make considerable contributions to medicine through his pupils Thus the roll of his assistant professors includes Surgeon Major TIMOTHY LEWIS (F.R.S.-elect when he died at 45) Sir DAVID BRUCE F.R.S and Sir DAVID SEMPLE. He was succeeded by Sir ALMROTH WRIGHT, F.R.S who in 1903 when the college came from Netley to London was in turn succeeded by Sir WILLIAM LEISHMAN F.R.S In 1914 and again from 1919 to 1921 the chair was held by Colonel S LYLE CUMMINS

In the decade preceding the first world war the value to the Army of a well organised pathology service was gradually recognised, and the training of regular Army pathologists proceeded steadily, with research by teams as well as individuals The war saw the development of mobile bacteriological laboratories, hospital laboratories and research laboratories and classical work was done on wound sepsis tetanus, gas gangrene shock, and many forms of infectious disease The war also showed the need for a degree of central direction of all these vital undertakings, and in 1919 the Pathology Directorate was founded at the War Office with LEISHMAN as first director assisted by DAVID HARVEY and A C H GRAY At the same time the Army Pathology Advisory Committee came into being—a body to which Sir FREDERICK HARRIS *director general of Army Medical Services* paid a special tribute last week. (Among its original members was Dr MERVYN GORDON F.R.S who attended every one of the seventy meetings during his lifetime) Under these arrangements development continued and research flourished especially in the 30s In India the pathology service profited greatly from the energy and drive of Major (now Major General) JOHN MANIFOLD Also in India, J S K. BOYD F.R.S, made his observations on dysentery bacilli, and L T POOLE worked with H E SHORTT of the I.M.S on the virus of sandfly fever At the Royal Army Medical College MARRIAN PERRY was collaborating with H. T FINDLAY and H J BENSTED on virulent typhoid strains in the production of vaccines and BOYD investigated the dosage and administration of tetanus toxoid

In 1939 the Army had a well developed and efficient pathological service capable of rapid expansion Under the directorship of Major General PERRY, the formation of an Army Blood Transfusion Service was undertaken by Sir LIONEL WHITBY who with such lieutenants as G A H BUTTLE W D'A. MAYCOCK, and G T L ARCHER made it one of the outstanding achievements of medicine in the war In 1941 Major General POOLE succeeding PERRY as director of pathology, took over a task now made immensely intricate by the requirements of large forces in widely separate theatres of war and by the need to arrange and assist many kinds of urgent research by

many different kinds of group How well that task was performed, by him and his assistant Lieut.-Colonel **BENSTED**, is known to many colleagues in all departments of medicine, who were thankful for his combination of high standards with a receptive mind and readiness to help After his retirement in 1945, the directorship was filled, for shorter periods, by Brigadier **BOYD**, by Brigadier **FINDLAY**, and by Major-General **SACHS**, from whose lecture at the college on April 27 we have drawn many of the facts of this outline Since 1953 the director has been Brigadier **ARCHER**, who arranged this memorable commemoration and at last week's dinner gave what he called the primary response to the toast of the Army Pathology Service proposed by Sir **LIONEL WHITBY** This is a toast with which a great many people have reason to associate themselves—even though they may never have heard of the service

Annotations

POLIOMYELITIS VACCINATION

MISGIVINGS about the new poliomyelitis vaccine,[1] lately put into extensive use in the United States, have been aggravated by last week's news that a number of children have fallen ill with paralytic poliomyelitis shortly after vaccination It is reported that 35 children have had paralytic poliomyelitis within a short time of vaccination,[2] and 2 have died Almost all these children had been injected with vaccine prepared by the Cutter Laboratories, of Berkeley, California, and supplies from this manufacturer have been recalled In the States of Idaho and California the immunisation programme has been stopped for the time being In Washington the situation has been examined by a group of advisers, including Dr Salk, and they have recommended that inoculations should continue[3] About 4 million people, nearly all children, have so far had a first injection In this country the Medical Research Council decided on Monday that their trials would not start until fuller reports of the American results were available

There are three possible explanations of what has happened First, the children may have been going to get poliomyelitis anyway, and vaccination was too late to have any preventive action Second, the children may have been carriers of poliomyelitis virus, and vaccination acted as a provoking stimulus in a similar way to pertussis and diphtheria immunisation Third, the vaccine may have contained live virus At present there is not enough evidence to decide which explanation is correct, but the third seems the most likely As there is nothing definite to suggest that vaccine manufactured by other laboratories is liable to produce paralytic poliomyelitis, it may be that the virus in certain batches of the Cutter vaccine had been incompletely inactivated

If it should turn out that the vaccine contained live virus two important questions must be considered. Did the Cutter laboratories follow closely the technique of inactivation by formaldehyde recommended by Salk ? It seems unlikely that any firm would knowingly vary the procedure, and if these methods were in fact closely followed the margin of safety of this technique should be re examined In particular, there should be a thorough scrutiny, in a number of different laboratories, of the kinetics of inactivation of all three types of poliomyelitis virus by formaldehyde under various conditions The second question concerns the tests of safety which were applied to this particular vaccine Previously, vaccine had been tested to exclude the presence of live virus by tissue-culture techniques and by intracerebral inoculation of monkeys If the tests carried out on the suspect vaccine were not as rigorous as those applied during last year's vaccination trial, the remedy seems clear Many thousands of children received the Cutter vaccine, so the relatively small number of cases of paralytic poliomyelitis may mean that only a few infective virus particles remained in the vaccine On the other hand, if the vaccine passes the safety tests but is still suspect on the grounds of a statistical analysis of the incidence of poliomyelitis following its use, then we must think again about the safety tests Is it wise to apply the results of tests with scores of monkeys to the vaccination of hundreds of thousands of children? We hope that it will not be necessary to make these further inquiries, and that the postvaccination cases may turn out to be unrelated to the vaccine But at the moment it seems unlikely that the vaccine will escape all blame

ANÆSTHESIA IN OBSTETRICS

THE advances in anæsthesia in the past few years have usually been accompanied by administrative steps which have made the new techniques available to almost every patient who has to have an operation in this country But this scarcely applies to anæsthesia in obstetrics, and there are good reasons to reconsider the position in this branch of anæsthesia, as was done at a meeting of the section of obstetrics and gynæcology of the Royal Society of Medicine on April 22

There has been some uneasiness about an apparent increase in maternal deaths due to anæsthesia, but this may well be only a relative increase, brought about by a fall in the number of deaths from other causes One danger lies in giving general anæsthesia to a patient who has not been properly prepared for it, the mother is sometimes given food and drink almost up to the last moment, and there is occasionally, after prolonged labour, a gastric atony and a stomach full of fluid, which can remind the anæsthetist of paralytic ileus or intestinal obstruction Again, these anæsthetics are not always given by those thoroughly familiar with the drugs they are using, or with the particular points on which to concentrate during the administration Whenever anæsthetics are given to mothers in labour, suction apparatus should be close by, and the delivery table should be one which will tip both head up and head down The head-up position, with the use of a relaxant drug and the passage of a cuffed endotracheal tube, is perhaps the safest method in experienced hands Sometimes induction at least should be carried out in the lateral position

The dangers of general anæsthesia emphasise the case for local or regional analgesia whenever possible General anæsthetics are essential from time to time, for intra-uterine manipulations such as internal version and manual removal of a retained placenta, but these occasions could perhaps be chosen more carefully General anæsthesia is often adopted without question because it allows every conceivable procedure to be carried out but in many cases another and safer method might have been equally effective Local and regional blocks have difficulties and dangers of their own, but there are many impressive reports of series in which they have been successfully used Perineal field block is probably the safest for mother and baby properly carried out it will permit low, possibly mid-cavity, forceps delivery and it is particularly suitable for breech delivery As for domiciliary operations, modern antenatal care has made a high proportion of them straightforward, but the same dangers can threaten At the meeting at the Royal Society of Medicine last month, Dr R B Parker gave statistics from Birmingham which showed that the rate of maternal anæsthetic death was greater in hospital actice than in domiciliary obstetrics The domiciliary næsthetic is almost always chloroform, with or without her The dangers of chloroform are well known and s use is sharply condemned on all sides; but many ill mourn the passing of chloroform from hospital ractice, and miss the smooth induction and the exibility it affords At present there is nothing which uite replaces it for those who give most of the anæs hetics in hospital obstetrics

[3] *Times* May 2 1955

It seems that there is much useful information to be btained from a wide survey of anæsthetic mortality nd morbidity in obstetrics, both domiciliary and nstitutional This should take into account the circumstances of the operation the equipment available (such s tipping bed and suction apparatus) and the experience nd training of the anæsthetist

XERORADIOGRAPHY

Is a new form of X ray photography xeroradiography o wet chemicals are used to develop the latent photo aphic image The process is a photo electric one and as first described by Carlson in 1937 Although it has een in use in commercial photography for some time, edical applications are only now being investigated. he technique depends on the property of a group of ubstances, known as semi-conductors, to hold an elec tical charge in the dark but to allow it to leak away when xposed to light or X rays Of these substances the ost promising so far investigated is amorphous selenium xerographic plate consists of a metal base on which is posited a layer of selenium 120–150 µ thick. It is otected from light and mechanical damage by a cover milar to an ordinary photographic cassette Before e the plate is charged in a special chamber by a high ltage D.C. source, which gives the selenium a positive ectrostatic charge The plate is exposed in the normal ay and the image is developed by spraying a fine wder on the surface of the plate in another light oof chamber The powder is taken up by the surface the plate according to the amount of charge remaining d so an image appears It takes about 10 seconds to arge the plate and about 20 seconds to powder it diographically speaking these times are remarkably rt even compared with those possible by the rapid t processing methods now available and there is the ded advantage that no dark room is required. Indeed whole charging and powdering equipment can be ilt into a trolley 4 ft by 2 ft or less and tucked into any rner of the X ray room or operating theatre Costs problematical but the charging and powdering achine may cost from £200 to £500 and the plates about each and since these can be re used indefinitely the ethod offers a cheerful prospect of reducing costs

The quality of the image is a more debatable point. The rograph is rather like an etching in black and white d it is viewed by reflected light To the unaccustomed e at least it is more difficult to interpret than e conventional radiograph. The image is of low ntrast, and soft tissue and bones are easily distinguishable on the same plate The powder tends to build up lines along the margins of the more dense parts of the age and this enhances the contrast and the clarity detail Fine wire grids as close as 1200 to the inch can resolved whereas, with normal film detail deteriorates 180 lines per inch[1] At the present stage of develop ent the speed of the xerograph is not all it might be ing about the same as that of non screen film; posures are therefore unacceptably long for the heavier rts of the body Another disadvantage is that a rmanent record can be made only by photographing e xerograph on miniature film or by copying it electrically; this would be a particular drawback when a ries of radiographs has to be inspected regularly or hen it is likely that one or more films will be needed for future reference Further research into the possibility of using a translucent base, to allow inspection by transmitted light, and of reducing the exposure required may make the method more useful medically

Much of the work on xeroradiography has been done in this country by W D Oliphant in Edinburgh, and trials of the equipment are well under way From America it is depressing to learn that the method is being considered as a means of replacing stocks of ordinary film fogged by atomic explosions But more cheerful news of the interesting medical possibilities should be coming shortly

SECOND AID

THE treatment of an injury begins almost as soon as it is sustained The patient himself—or a witness who renders assistance or tenders advice—is his first "doctor" From this haphazard beginning he passes through the hands of successively more experienced helpers until he undergoes definitive treatment His progress may involve a parent an older workmate, a resourceful bystander, a civilian or policeman trained in first-aid, the chemist,' a nurse, a doctor a hospital and perhaps ultimately a specialist in traumatic surgery or a team of specialists The more serious his injury the more likely he is to follow this sequence to its end but how far he travels along the line depends also partly on chance and partly on the organisation Many of those who get no further than one of the early stages might have profited if they had been carried at least one stage further There is still much avoidable disability because patients with trivial injuries are not brought to clinics and services which are there to treat them until some complication has set in Of those sent to hospitals well fitted to deal with them some have suffered by delay in the preliminary "filtering some by well meaning but unenlightened handling on the way, and some because no one appreciated that a patient with a dangerous condition may not look dangerously ill

One particular section of this line is receiving increasing attention, as is well illustrated by two publications from the committee on trauma of the American College of Surgeons[1][2] One is the fifth edition of a monograph on the treatment of fractures the other a new companion to it is a similar work on the early care of soft tissue injuries The growing realisation of the importance of this second type of injury is reflected in the size of the monograph on it, which is twice that of the other Both combine simplicity brevity and absence of distracting controversy with remarkable comprehensiveness. Both may be accepted as a concise presentation of the most authoritative views in contemporary American teaching Both emphasise the value—often the *supreme* value—of correct *early* treatment which may lie in the hands of younger and comparatively inexperienced people They are aimed at interns and residents in the hospital who serve their periods in the emergency room" and at all doctors who have to do with the treatment of injuries but there is sufficient indication of the later specialised treatment for readers to understand why initial decisions have a vital influence on the final result

It is neither possible nor desirable for every minor injury to be submitted to highly specialised services. Nevertheless much delay in recovery may be avoided if those responsible for early care are guided to select accurately the more serious injuries and if they are briefed on the best way to deal with these before they are sent on Senior surgeons cannot sit all day in their casualty departments waiting for the next accident but they can make clear their wishes on early treatment and they can inform their juniors of the type of surgery likely to be required later in the day House-surgeons casualty officers, and "interns" usually have a comparatively brief term of office Many casualty departments and accident rooms have a periodicity in the standard of their service which corresponds with the length of the doctor's appointment Continuity of policy among successive holders is difficult to maintain, and these publications could do much to maintain it

ANTI-HISTAMINES AS HYPNOTICS

MANY anti histamine drugs in common use cause drowsiness, and that is usually unwelcome, but Straus et al,[1] in New York, have tried to decide whether this property can be turned to good account In a controlled experiment they have shown that the anti histamine, methapyrilene hydrochloride, in a dose of 50 mg by mouth, is as effective a hypnotic as 100 mg (gr 1½) of phenobarbitone This work confirms a general clinical impression, but anti-histamine drugs are unlikely to be widely accepted as alternative hypnotics to barbiturates

The experiment is of interest because of the methods employed in evaluating methapyrilene's hypnotic powers It was conducted on the "double-blind" principle, and methapyrilene was compared with a positive control (in this case phenobarbitone) and with a negative control (an inert capsule) The "cross over" technique was used—that is, all patients received all the substances being tested, but different sequences were followed in the various patients The choice of phenobarbitone as a positive control was perhaps unfortunate, for this drug is usually classed as a sedative rather than a hypnotic, and 200 mg (gr 3) of pentobarbitone would perhaps have been a better dose The greatest difficulty in an experiment of this kind is the selection of suitable patients Ideally (for unquestionable results), no one should sleep well after the placebo and all should sleep well after the positive control As the experiment was designed with an evaluation period of three weeks, it was necessary to select patients with chronic insomnia relatively uninfluenced by factors other than the change of medication Obviously the ideal conditions will rarely be obtained in practice, and, in fact, although Straus et al selected their 54 subjects with great care (only male patients were included), 30% showed an excellent response to the placebo The number of variables might have been less if each drug had been given only once to each patient, and if a larger number of patients had been used

The criteria of a night's sleep were the patients' own statements in a standard interview and the observations of a night nurse who shone a flashlight on each patient regularly during the night The nurse's impression of the patient's sleep was consistently better than that of the patient himself Other methods of measuring sleep, notably electro encephalography, were considered but all were rejected as inferior to the simpler tests employed Each night's sleep was classified and scored, and the data so obtained were statistically analysed in considerable detail The conclusion was that, as a hypnotic, methapyrilene was superior to the placebo and about equal to phenobarbitone The refinement of the statistical methods seems scarcely suited to the analysis of data measured on an arbitrary scale, and in the presence of many uncontrolled and often unidentifiable variables But Straus and his colleagues have given a very good example of a carefully designed experiment, and it would be a great advance if all new hypnotics were examined with equal care On the other hand, some may think that the information obtained by an elaborate study like this still falls short of scientific proof, and that the judgment of an experienced clinician, based on the observation of relatively few patients (and perhaps of himself on the night train to Scotland), is still a very good measure of what a hypnotic is really worth

ORTHOSTATIC PROTEINURIA

ORTHOSTATIC proteinuria is a condition in which th urine is normal while the patient is lying down, b contains protein when he is up and about It is usual considered to be a temporary and harmless anomal King,[1] in a study of 4000 cases of proteinuria in th United States army, has put forward the view that i is often permanent and not completely benign Th proteinuria persisted for three years in 131 of 170 case and many of these gave a history of proteinuria for u to ten years previously These observations agree wi those of Thorp and Wakefield[2] who found that 43 o 64 patients still had proteinuria after six years Th incidence of anatomical abnormalities of the kidneys an ureters in cases of orthostatic proteinuria is unusual high King found that 18 of 56 cases showed radi logical abnormalities by intravenous pyelography, an Young et al[3] have reported a similar proportion

The amount of protein lost in the urine may occasi ally be as great as in severe glomerulonephritis. Co centrations of protein as high as 4 g per 100 ml in sing urine specimens have been reported,[4] and Wolman states that the range of concentration in 24 hour spe mens is 15–545 mg per 100 ml, with a mean value o 74 mg per 100 ml The highest level corresponds to protein loss of about 8 g daily, equalling that found many examples of the nephrotic syndrome Electr phoresis showed that the proportion of globulin w unusually high[1]

There is still controversy about the cause of th condition Sonne[6] considered it was the result of co pression of the left renal vein as it crossed the abdomi aorta, and Bull[7] thought that rotation of the liv during lordosis compressed the inferior vena cava an so increased caval venous pressure King believes th further experimental evidence is necessary before eith of these hypotheses can be accepted King and Baldw have confirmed Bull's finding[7] that there is a profou fall in glomerular filtration rate and renal plasma fl in the erect lordotic posture, but they found no signific difference in filtration rate or plasma flow when ca of orthostatic proteinuria were compared with n proteinuric controls

The immediate prognosis in cases of ortho proteinuria is good, and it is certain that this anom does not indicate rapidly progressive renal dise Insurance statistics suggest, however, that the morta over many years is significantly greater than in cont "good life" cases Daley[9] states that actuarial statis published in 1938 showed a mortality in 52,000 case "intermittent" proteinuria of 128% of the expec level Further experience[1] up to 1951 suggests t the mortality rises to 150% of the expected figure that the extra deaths are most commonly due cardiovascular disease

Special Articles

CANCER

THE PSYCHOLOGICAL DISEASE

MALCOLM DONALDSON
F R C S F R C O G
DIRECTOR OF CANCER SURVEY YORKSHIRE COUNCIL, BRITISH EMPIRE CANCER CAMPAIGN

THE title of this article is not intended to suggest that cancer is a ' psychosomatic ' disease but rather to point out that besides the physical disease of cancer there is a psychological condition of cancer apprehension,' which affects almost the whole population This mental attitude is present in many members of the medical profession although in their case it assumes a rather different form and the fact that discussions on cancer education often generate more heat than arguments about politics or even religion, may in itself be additional proof of my thesis.

PREVALENCE

Is this apprehension of direct harm to the community ? Clearly in its acute form of cancerphobia ' it causes great harm to some individuals and each year a few suicides are recorded, where the unfortunate victim is found to be without trace of the disease Mental worry even if only intermittent as is often the case in cancer apprehension must also be harmful to the individual, and, if widespread, must surely be bad for the community What evidence is there that cancer apprehension is widespread ? There is no statistical evidence but surveys in America are suggestive and a survey among 1200 Manchester women[1] showed that three-quarters considered it the most alarming of all diseases

Every doctor has patients who visit him with vague symptoms, and if at the end of an examination the doctor says I am glad to say that I can find nothing serious, no evidence of tumour or cancer ' as often as not the patient will say Thank God, that was what I was really worried about " Such cases clearly indicate the presence of cancer apprehension Unfortunately some of these cancer-apprehensive patients are not recognised they are labelled neurotics or neurasthenics and they continue to live on the doctor s doorstep in the hope of being reassured

Reluctance in the dislike to mention the word cancer is also evidence of apprehension Obituary notices refer to a ' long and painful illness bravely borne (Heart-disease with its greater mortality is never mentioned in this way) Doctors even if they are not anxious about themselves are anxious that nobody should hear or think about cancer Whether a patient should be told the truth must depend on circumstances. Often the relatives are told but the patient deceived—if he or she can be deceived which is doubtful Later if the relatives think they have cancer the doctor finds it hard to convince them that there is no cancer In the Manchester survey already mentioned 40% of the women thought that the patient should be told Any attempt to keep the disease ' hush hush ' must fail because it is met with so frequently Each year in this country about half a million are added to the number of people who have already come in direct contact with a patient

An incident illustrating the fatalistic and defeatist attitude of some doctors towards cancer happened to me When I entered hospital to be investigated for a possible gastric carcinoma one of my colleagues said Of course you know you have not got a carcinoma you would never go into hospital On leaving hospital after an exploratory laparotomy which fortunately proved negative another colleague said ' Of course you were the only person who thought it might be carcinoma Would these remarks have been made about any other disease ?

Though there may be a difference in opinion as to how widespread is cancer apprehension there is no doubt that it often delays diagnosis There are no figures to show how many patients put off a visit to the doctor for fear that the condition may be cancer but the answers given in the Manchester survey to the question why women are more frightened of getting cancer than any other disease, are probably also the reasons for delay in reporting symptoms to a doctor Of these the answers that it is fatal ' ' incurable ' ' gets worse " only know when it is too late,' and " because of the pain and suffering " head the list

There are figures, however which show the time that elapses after a patient has noticed a symptom before he or she seeks advice Stocks[2] reported that the median number of months interval between the earliest symptom and the start of treatment for cancer of the uterus was 5 7 months (taken from the figures supplied by twenty six hospitals), for the breast 6 months and for the rectum 5 6 months Figures collected by the Yorkshire council of the British Empire Cancer Campaign show much the same delay

TREATMENT

What can be done to lessen apprehension and thus obtain earlier diagnosis ? Surely the answer can only be to educate the public by giving information about the accessible cancers and by encouraging people to talk about cancer, and thus to bring their fear to the surface and to face it Those who oppose this plan do so chiefly on the grounds that attempts to educate the public will increase cancer apprehension and fear If true this would certainly defeat the object of obtaining earlier diagnosis Psychiatrists could help us to settle this question, but unfortunately, though interested in the treatment of true cancerphobia patients they have little time to study the problem.

The Yorkshire Council of the B E C C, with the help of some of the local health authorities in the area, have lately given 220 lectures to the public on cancer education At the end of most of these a printed slip is passed to each member of the audience asking whether the lecture has increased their worry and such lectures should not be given or whether it has diminished their worry and more lectures should be given The results from 5740 votes shows 99 1% in favour 0·2% against while 0·7% put a question mark

The other argument used against cancer education is that even if patients are persuaded to visit their doctor when a symptom is noticed the number of cancers treated in the early stage will not be greatly increased because of the large number of growths that disseminate before giving rise to symptoms It is very doubtful *whether this is true* of the accessible cancers which are the only ones that cancer education can hope to benefit

Figures quoted in support of this are usually based on the results of treatment within six months of noticing symptoms and after six months This is, in fact a *comparison between two different types of growth* The first set of figures includes all the rapidly growing tumours as well as the slow growing well-differentiated tumours whereas the second set includes only *the well* differentiated, slow growing ones The figures needed are those for 0–1 month 1–2 months 2–3 months &c., for the accessible cancers In the Manchester survey 76% agreed that there should be freer public discussion of the symptoms

If the psychiatrists could confirm the psychological benefit of cancer education it would be a great help to those of us who are trying to obtain earlier diagnosis

WORK OF A GERIATRIC UNIT

A SURVEY OF 13,500 PATIENTS

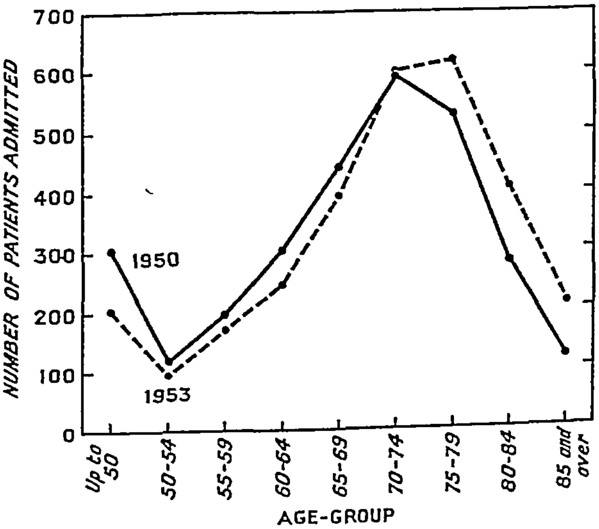
KENNETH B GIBSON
M.B E , M D Lpool, M.R C P
LATE PHYSICIAN SUPERINTENDENT, NEWSHAM GENERAL HOSPITAL, LIVERPOOL

I HAVE recently completed a survey of all inpatients treated in the 18 medical geriatric wards of this hospital, from the beginning of 1950 to the end of June, 1954 Of these 13,500 patients, 11,000 were over sixty years of age, and some of the findings seem likely to interest others concerned with planning hospital care for the elderly

The Background

Newsham, like many of the country's larger hospitals, had a humble origin as a 19th-century poor-law institution As time went on, buildings designed as dormitories for the able-bodied gradually came to be used as wards for the growing number of infirm inmates The occupants of these wards were mostly old and bedfast Some were merely frail and homeless, some were disabled by chronic disease, some were acutely ill For several decades there were few facilities for medical investigation, treatment, or rehabilitation , but a high standard of nursing care, provided by a hard-working though largely untrained staff, tended to conceal the defects of the system These defects were aggravated and became more conspicuous during the second world war, when a depleted staff had to meet the additional demands of the Emergency Medical Service Its new rôle as an emergency hospital led to the appointment of its first two resident medical officers, but the war precluded any large scale improvement

In 1946 there began a phase of development which has continued ever since, with a minimum of interruption due to the change of management in 1948 Staff was augmented , equipment was provided , and, despite financial restrictions and material shortages, some modest but useful structural alterations have been achieved The original programme for the modernisation of the hospital's 34 wards is now nearly complete, and ancillary services have been steadily expanded to meet the increasing demand for investigation and rehabilitation of a medical staff which now numbers 36 At the beginning of the period of this survey there were already adequate facilities for radiology, pathology, physiotherapy, and occupational therapy , and an almoner's department dealt with social problems By the end, all these departments had been further improved and ma new ventures had been started—e g , there was a chirop dist, a dispensing optician, and a cardiographer, t hospital had its first operating-theatre , and a sm follow-up clinic had been set going



of the ages of patients admitted in 1950 and 1953.

The number of beds in medical geriatric wards inev ably fluctuated during four and a half years, and t over all result was a slight reduction from about 740 in 1950 to 707 in 1954 For instance, 16 beds were lo when part of a male ward was converted to enlarge th X-ray department , others were sacrificed to mu needed sanitary improvements in several wards In t review I have excluded 2 wards for senile dement a 1 mixed psychiatric ward Also I have ignored int departmental transfers , but this two way traffic is to small to influence the main findings

Most of the patients in the survey were admitted a the request of their own general practitioners Durin the greater part of each year there is a waiting list, a patients are admitted in their turn unless their doct ask for priority Apart from an occasional need to a the relative urgency of claims for priority, there was n selection or screening of admissions by the hospita medical staff About 9–10% of each year's admiss were transfers from hostels and other hospitals

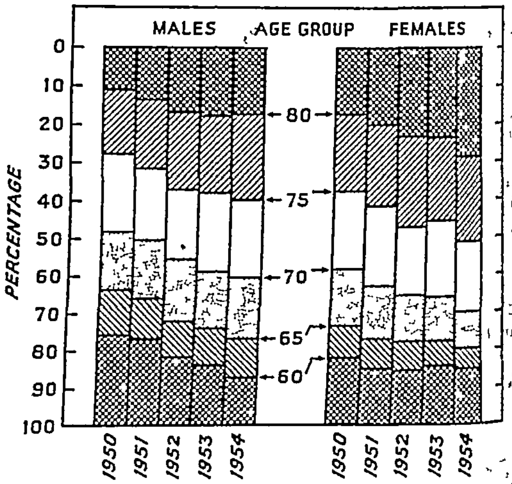


Fig 2—The changing age-distribution of men and women admit geriatric wards in 1950–54 (1954 percentages based on adm during the first six months of the year)

The 18 wards included in the survey form a compo geriatric unit, which undertakes not only investigat treatment, and rehabilitation, but also the long te care of patients with chronic disease who cannot adequately nursed outside hospital The latter are segregrated in a separate annexe In general, a wa or group of wards, retains its own long stay patie but tends to concentrate them as a matter of convenie This system is largely dictated by local conditions offers many advantages Both medical and nursing share the variety and interest of different types of w and most elderly patients like to remain with the staff throughout their stay Moreover, the atmosph of an active ward helps to sustain an expectatio ultimate discharge in the minds both of patients their relatives

Analysis of Results

Age of Patients

Patients over seventy years age of increased f 1516 (52 8% of all admissions) in 1950 to 1822 (6 in 1953, and represented 65 2% of all patients adm in the first six months of 1954 Higher in the age-sc the proportion of admissions over eighty years of increased from 13 9% in 1950 to 23 2% in 1953 (fig 1

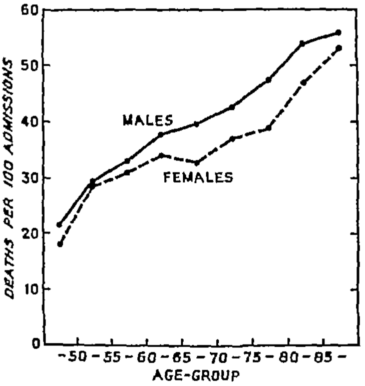

Fig. 3—Mortality of whole series at different ages.

Like other geriatric units (Thomson 1949 Morton 1952 Amulree et al. 1952 Andrews and Wilson 1953) we found that men tend to be admitted at an earlier age than women (fig 2) In both sexes the age on admission rose in successive years, but women showed a greater increase than men The increasing proportion of men in the older age groups depended partly on a reduction in the proportion under sixty years of age while the numbers of women under sixty varied very little

Mortality

As in the general population, mortality increased with age after fifty years and in every age group women had a lower mortality than men (fig 3) Death rates per 100 admissions varied from 18·0 (women under fifty) to 55·4 (men aged eighty five and over) the death rate did not pass the 50% level until age eighty for men and eighty five for women

Despite the increasing age of patients admitted mortality rates fell during 1950–53 Annual rates per 100 admissions (table I) are convenient for comparison though not all the patients dying in a given year were admitted in that year The mortality of both sexes combined shows a fall in each year after 1950 with the exception of 1951 (This interruption of the downward trend seems to have been caused by a severe influenza epidemic in January and February of that year Mortality in this epidemic was particularly high in the elderly and the hospital is situated in an area which was badly affected) But table II shows that the combined mortality rates conceal an important sex difference The over all decline in mortality depends entirely on a fall in female rates (from 38·2% in 1950 to 33·4% in 1953) which offset a smaller rise in the male rates (from 39·5% in 1950 to 42·8% in 1953) The general increase in male mortality depends almost entirely on younger patients however for in the death rates of men aged sixty and over the rise is less definite An unexpected finding was that both sexes had a falling mortality in the seventy five and over age group For this group the death rates per 100 admissions were

TABLE I—MORTALITY IN GERIATRIC WARDS 1950–53

Year	Patients of all ages			Patients aged 60 and over		
	Admissions	Deaths	Death rate	Admissions	Deaths	Death rate
1950	2877	1121	39·0	2256	963	42·6
1951	3216	1301	40·5	2587	1136	43·9
1952	3017	1166	38·6	2522	1034	41·0
1953	2922	1109	37·9	2456	995	40·5

	1950	1951	1952	1953
Men	50·5	48·0	50·3	50·1
Women	48·5	47·0	41·5	39·5

Turnover

The highest annual total of admissions was 3216 in the year 1951—an increase of 339 over 1950 Rather more than half this increase in turnover can reasonably be attributed to the influenza epidemic, for in 1951 there were 173 more discharges as well as 180 more deaths than in 1950 Admissions then declined to 3017 in 1952, and again to 2922 in 1953 Even in 1953 however admissions and discharges remained higher than in 1950, and the downward trend appears to have been checked in 1954 for 1523 patients were admitted in the first six months of that year

The decline in turnover between 1951 and 1953—a difference of 294 admissions—certainly cannot be explained by the small reduction in beds already mentioned; for a loss of 24 beds would account, at 1953 rates of turnover for 138 admissions at most But this type of calculation over simplifies a controversial issue On the one hand some of the improvements obtained in exchange for lost beds might be expected indirectly to increase turnover On the other hand any reduction in beds will tend to reduce admissions and improvements while they may at once increase comfort or convenience, will not increase turnover until this deficit is made good.

TABLE II—COMPARATIVE MORTALITY OF MEN AND WOMEN PATIENTS

Sex	Year	Patients of all ages			Patients aged 60 and over		
		Admissions	Deaths	Death rate	Admissions	Deaths	Death rate
Men	1950	1588	628	39·5	1200	534	44·5
	1951	1716	696	40·6	1316	596	45·3
	1952	1516	617	40·7	1238	538	43·5
	1953	1418	607	42·8	1187	536	45·2
Women	1950	1289	493	38·2	1056	429	40·6
	1951	1500	605	40·3	1271	540	42·5
	1952	1501	549	36·6	1284	496	38·6
	1953	1504	502	33·4	1269	459	36·3

Table III suggests that the decline in admissions during these years depends mainly on falling mortality The decrease in deaths was almost twice as great as that in discharges: moreover if each is expressed as a rate per 100 admissions the death rate fell by 2·6% while the discharge rate increased by 2·3%

These findings illustrate an unpalatable truth—and a growing problem Not every patient whose life is saved in a geriatric unit can be discharged, and falling mortality is likely to reduce the number of patients who can be served by each geriatric bed

The numbers of discharges quoted above include patients transferred to hostels and other hospitals In 1951 337 were transferred but in 1953 only 266 and their corresponding rate per 100 admissions fell from 10·5 to 9·1% In the same period patients discharged to their own homes showed a smaller reduction in actual

TABLE III—TURNOVER

Year	Admissions	Discharges		Deaths	
		Numbers	Rate	Numbers	Rate
1951	3216	[illegible]	59·9	1301	40·5
1952	3017	[illegible]	61·4	1166	38·6
1953	2922	1817	62·2	1109	37·9
Difference 1951–53	−294	−108	+2·3	−192	−2·6

TABLE IV—TRANSFERS AND DISCHARGES

—	1951	1953	Difference
Transferred—			
to other hospitals	81	49	32
to hostels	256	217	39
Total transfers	337 (*10 5%*)	266 (*9 1%*)	71 (*−1 4%*)
Discharged to own homes	1588 (*49 4%*)	1551 (*53 0%*)	37 (*+3 6%*)

numbers and their rate per 100 admissions rose from 49 4 to 53 0% (table IV)

The fall in the transfers to other hospitals presumably reflects the development of Newsham and its growing independence of outside facilities The reason for the fall in transfers to hostels is more complex The number of places in local hostels for the elderly has increased in recent years, yet competition for vacancies seems to increase The turnover in the geriatric wards could probably be slightly higher if there were more hostel vacancies But the main problem arises from patients who, even after all possible active treatment, cannot be discharged to their own homes and are too frail to be transferred to most hostels of existing types It is an encouraging sign for the future that locally, at least, the need for a more sheltered type of hostel is recognised, and the hospital is collaborating with both the Liverpool public-health department and the Liverpool Personal Service Society to augment "half-way" accommodation for "frail ambulants"

Length of Stay

The study of length of stay in geriatric wards is complicated by a few patients who remain for long periods and whose final length of stay was still unknown when this survey was made For example, 56 patients admitted in 1949 or earlier, and a further 23 admitted in 1950, still occupied geriatric beds at the end of 1953 I have therefore divided all admissions into two groups —long term patients who stayed over twelve months, and those who left hospital within this arbitrary limit of twelve months According to this classification, 2 5% of the men, 5 2% of the women, and 3 8% of both sexes admitted in 1950–52 were long-term patients The proportion of each sex increased with age, and in every age group women show a higher proportion than men (table V)

TABLE V—PATIENTS ADMITTED 1950–52 *WITH LENGTH OF* STAY EXCEEDING TWELVE MONTHS

Age	Men	Women	Total
Under 60	15 (*1 4%*)	23 (*3 4%*)	38 (*2 2%*)
60–69	31 (*2 4%*)	36 (*3 8%*)	67 (*3 0%*)
70–79	52 (*2 9%*)	91 (*5 1%*)	143 (*4 0%*)
80 and over	22 (*3 3%*)	74 (*8 4%*)	96 (*6 2%*)
Total all ages	120 (*2 5%*)	224 (*5 2%*)	344 (*3 8%*)
Total 60 and over	*105 (2 8%)*	*201 (5 6%)*	*306 (4 2%)*

Fig 4 shows the *proportion* of long-term patients of different ages in 1950, 1951, and 1952 Though the proportion to total admissions remains about the same, there is a gratifying fall in the numbers and proportion of patients of seventy-five and over staying longer than twelve months

Admitted in 1950	65 patients	(*7 0%*)
" " *1951*	*60* "	(*5 1%*)
" " 1952	50 "	(*4 0%*)

Choosing 1951 as an example, and excluding all long-term patients admitted in that year (4 1% of total), I have shown in fig 5 the mean duration of stay of all other patients—i e , those who left the unit within twelve months In this group, again, there is a remarkably close correlation between age and length of stay Both sexes show a steadily increasing length of stay in cessive age groups, but in every group the average of women was longer than that of men These patie also provide information about the effect on turnover changes in mortality in each sex the average stay before death was much shorter than that before discharge (table VI)

A few of the patients admitted in each year of the survey are still in hospital, *and it is not* yet known to what extent they will influence the average stay of the group As an example of the serious distortion of average values which can be caused by a small minority long stay patients, table VII shows the average stay long term and other patients who left the unit in 19 Of the 3226 patients who died or were discharged, *had an individual stay of less than twelve months* the average stay was 47 days, while 121 long patients had stayed for an average of 970 days, or more than two and a half years A minority of 3 8% long term patients raised the average stay of the 96 2% ma from 47 days to 81 days, and accounted for nearly 45 of the quarter million patient days spent in hospital the whole group

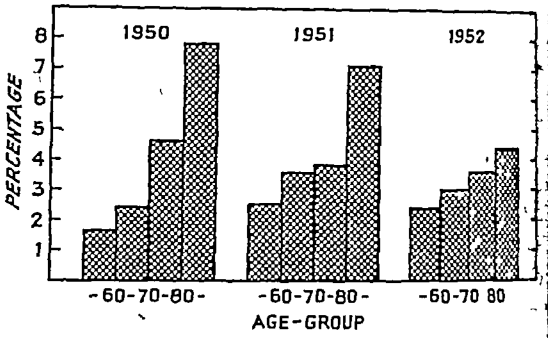

Fig 4—Proportion of each year s admissions with a stay exce twelve months, 1950–52.

Use of Beds

An important group of long term patients fail qualify for inclusion in the usual statistics of admiss discharges, and deaths in any one year In 1950, example, 187 beds were occupied throughout the *by patients who were admitted before* Jan 1 and remained on Dec 31 The number of beds occup throughout a whole year fell to 176 in 1951, but rose

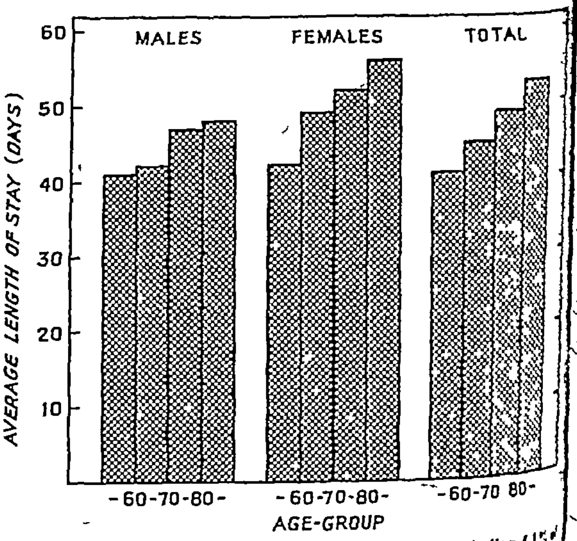

Fig 5—Average stay of patients admitted in 1951, excluding 4 1% total who remained longer than twelve months

TABLE VI—LENGTH OF STAY BEFORE DISCHARGE OR DEATH

—	Average stay (days)					
	All ages			Aged 60 and over		
	Males	Females	Total	Males	Females	Total
Before discharge	52	54	53	56	57	56
„ death	33	46	39	32	46	39
All patients	44	51	47	45	52	48

96 in 1952, and to 201 in 1953 Women patients caused almost the whole of the increase

It is true that most elderly patients occupy beds little longer than younger patients (Graham 1951 Amulree et al. 1952) Almost half (49%) of the patients leaving the unit in 1951 stayed less than one month and 85% had an average stay of less than one month Yet even a small proportion of long-stay patients in the intake of successive years can cause serious cumulative obstruction of beds Although only 3 8% of all patients admitted in 1950–52 stayed longer than twelve months more than 28% of the unit s 707 beds were occupied throughout 1953 by long term patients admitted before Jan 1, 1953 Of the 201 patients who occupied beds throughout 1953, 141 were women (who occupied 35% of 399 beds in female wards) and only 60 were men (who occupied 19% of the unit s 308 male beds) Table VIII shows that 145 (both sexes) had been admitted in the years 1950–52 and 56 in earlier years before the survey began 14 had completed ten years stay by the end of 1953 of whom were under sixty years of age at the time of admission —a reminder that younger victims of chronic disease who need hospital beds for long periods

TABLE VII—AVERAGE LENGTH OF STAY BY A SMALL MINORITY OF LONG-TERM PATIENTS BASED ON PATIENTS LEAVING GERIATRIC WARDS IN 1951

Classification by age and length of stay		Number of patients	% of total	Total patient days	Average stay (days)
All ages	Under one year	3105	96 2	145 640	46 9
	Over one year	121	3 8	117 326	969 6
	Total	3226	100·0	262 966	81 5
Aged 60 and over	Under one year	2474	95 8	118 120	47 8
	Over one year	110	4 2	99 476	904 3
	Total	2584	100 0	217 596	84 2

About a third of all long term patients leaving the unit between Jan 1, 1951 and Dec 31, 1953 were discharged or transferred :

	Discharged	Died	Total
1951	41	80	121
1952	37	73	110
1953	31	68	99
Total 1951–53	109	221	330

These proportions of discharges and deaths give a somewhat gloomy but far from hopeless picture of prognosis in long term patients

The unequal sex-distribution of the long term patients (table VIII) explains most of the apparent difference in the turnover of male and female beds in this series (table IX)

TABLE VIII—LONG-TERM PATIENTS REMAINING ON DEC 31 1953

Year of admission	Males	Females	Total
1952	22	49	71
1951	13	38	51
1950	6	17	23
1949	6	7	13
1948	5	6	11
1947	3	9	12
1946	—	4	4
1945	—	1	1
1944	—	1	1
Before 1944	5	9	14
Total	60	141	201

Demand for Beds

The demand for the unit s beds can be assessed from waiting lists, which have been counted weekly since the beginning of 1951 (table X)

The long waiting lists created by the influenza epidemic in the first quarter of 1951 were virtually cleared by the autumn of that year Thereafter the total numbers waiting in any one season show a steady increase. Once again however, this increase is not evenly distributed between the sexes Men show a slight increase but their rising trend appears to have been checked in the first part of 1954 Women show a greater and more consistent increase from October, 1951 to June 1954 In 1951 male and female waiting lists were about equal, but in 1953 the female list was almost twice as large as the male list

TABLE IX—ADMISSIONS PER BED IN 1953

—	Males	Females	Total
Number of admissions	1418	1504	2922
Number of beds	308	399	707
Admissions per bed	4·60	3 77	4 13
Beds blocked throughout the year	60	141	201
Beds available for admissions	248	258	506
Admissions per available bed	5 71	5 83	5 77

The major deficiency at present is clearly in female beds 90 have been made available in a newly opened hospital, administered by the same management committee and it is planned to increase this accommodation to over 250 beds within the next twelve months.

Discussion

Many social changes contribute to the growing demand for institutional care of the elderly but the basic cause is the changing age distribution of the population The Royal Commission on Population (1949) taking the year 1947 as a datum line and assuming a falling mortality, estimated that people over sixty five years of age would show an increase of 26% by 1963 and of 64% by 1977 The latest statistics show that in 1947–52 these age groups did in fact increase by 7 7%—an annual rate of 1 5%—which is in close agreement with the estimate. Of even greater importance to the hospital services is the redistribution within the age structure of these older age groups Between 1947 and 1952 the number of people aged seventy five and over increased by 14%—almost double the rate of those aged sixty five and over (Annual Abstract of Statistics 1952 and 1953)

TABLE X—AVERAGE WAITING LISTS JANUARY 1951 TO JUNE, 1954 BASED ON WEEKLY COUNTS

Period of year	Males				Females				Total			
	1951	1952	1953	1954	1951	1952	1953	1954	1951	1952	1953	1954
1st quarter	181	66	61	57	133	44	79	111	317	110	140	162
2nd „	21	18	34	34	47	37	65	91	69	49	98	126
3rd „	6	1	21		22	8	29		29	9	53	
4th „	3	10	15		9	36	66		12	44	81	
Whole year	53	24	33		54	27	60		106	63	93	

In the general population as in the present series, increasing age is more obvious among women than among men In these five years women aged sixty five and over increased by 10% men of the same age by only 4% The sex-difference in the age groups over seventy five is less conspicuous but women show a greater rate of increase than males. Although our local population (Merseyside Conurbation) has a lower percentage of elderly people than the national population there are 173 women to every 100 men of over seventy-five on Merseyside, compared with 162 women to every 100 men in England and Wales (Registrar-General 1952)

The high rate of increase in the age-groups over seventy-five affects the hospital services in two ways First, because among the over-seventies there is a sharp increase in frailty, dependence on others, and demand for institutional care (Sheldon 1950, 1954) For example, the 1951 census returns (1% sample) showed that 48% of men remained in whole-time employment after the age of sixty-five, but only 20% after the age of seventy Similarly, the Wolverhampton survey (Sheldon 1948) showed that the proportion of women undertaking the sole domestic care of their household remained fairly constant at about 50% between the ages of sixty and seventy-four, but declined to 40% after seventy five and to 18% after eighty years As long as morbidity continues at present levels, any increase in these older age groups must cause a disproportionate rise in the demand for hospital beds Lowe and McKeown (1950) calculated age specific rates for patients in hospitals for the chronic sick per 1000 of the Birmingham population their rates show a remarkably sharp increase in the older groups

Age	*Rate per 1000*
55–64	1 53
65–74	6 38
75–84	22 21
85 +	58 93

This survey also suggests that an increase in the age of patients admitted to geriatric beds will tend to reduce turnover—both by increasing the proportion of long stay patients and by lengthening the average stay of those discharged

The Wolverhampton survey drew attention to the fact that the lower mortality of old women is accompanied by a morbidity higher than that of old men, and there has since been ample evidence that the proportion of hospital accommodation required for older women is far greater than can be explained by their greater numbers Greenwood (1949), Exton-Smith (1952), Morton (1952), and Andrews and Wilson (1953) all quote examples of the disproportionate demand for female beds, and in the Birmingham survey women had a higher age specific rate than men at all ages after seventy-five

Estimates of future hospital scales based on the total numbers of both sexes, either in the whole population or in the combined age-groups over sixty or sixty-five years, can have only a short-term reliability Long term planning should take account of the changing age-structure and sex distribution of the older population

The difficulties of long term planning have been discussed in a P E P study (1954), which reviews basic assumptions about trends in birth rates and mortality, and suggests that previous estimates of the economic burden of old age may have been exaggerated Fortunately changes in the birth-rate cannot directly increase the burden on the geriatrician for sixty years or more —though the size of the working population will influence the amount of the national income available for welfare services, including hospitals The future demand on the hospital services will depend both on the numbers of old people alive, and on the incidence of disease among them It is a melancholy thought that many of the problems of old age are a by-product of unbalanced medical progress We can prevent or cure many of the diseases which used to kill we cannot yet control many of the more insidious diseases which disable those who survive into an extended old age The control of arterial degeneration would probably do more than any other scientific advance to reduce the social and economic problems as well as the suffering of old age Extra longevity without lower morbidity is a doubtful blessing for most of us Old age must be made healthier and more useful if it is to be anything but an increasing burden, both to the individual and to the community

It is a pleasure to acknowledge the willing assistance of many members of the hospital staff I am especially indebted to Miss C Ledsham and others who helped in the tedious work of extracting the basic figures for this survey

SALARIES IN THE PUBLIC-HEALTH SERVICE

UNDER an Industrial Court award which operates as from Jan 1, 1955, medical officers of health, senior medical officers, and medical officers in departments (assistant medical officers) are to receive increases in salary ranging from £175 to £200 The new salary scales are as follows

Medical officers of health

Population Group	*Commencing salary*	*Increments*
Not exceeding		
75,000	£1625–£1830	4 × £51 10s
100,000	£1730–£2040	6 × £51 10s
150 000	£1940–£2250	6 × £51 10s
250 000	£2150–£2450	2 × £100 1 × £50
400,000	£2400–£2700	2 × £100 1 × £50
600,000	£2500–£2900	3 × £100
Over 600 000	At discretion	At discretion

Senior medical officers
£1415 × 50–£1765 × 65–£1830

Medical officers in departments (assistant medical officers)
£975 × 50–£1375

The court found against a proposal to introduce in Scotland a salary scale for a medical officer of health with a population group not exceeding 60,000

WHOLE-TIME AND PART-TIME CONSULTANTS

THE Joint Consultants Committees have had recent discussions with the Ministry of Health and the Department of Health for Scotland about whole time and maximum part time service for consultants in the National Health Service, and the following is an agreed statement of the position

It is recognised that some consultants, while prepared to devote substantially the whole of their time to hospital work and to give it priority on all occasions, would prefer a maximum part-time to a whole time contract Ever since 1948 it has been the Ministry's view that, subject always to the needs of the hospital service, employing boards should in this matter take into account the circumstances and preferences of the consultants concerned While there has been no previous statement on this point as regards Scotland, the practice in that country has been similar

Where a new appointment is being made this means that, except where the board decides that the needs of the hospital service (considered in conjunction with the needs of the local health services where the consultant is to undertake duties on behalf of a local authority) demand a whole time appointment, the competition should be thrown open to all applicants who are prepared to give substantially the whole of their time to the post, whether they prefer a whole-time or a maximum part-time contract In such a case the successful candidate should e asked to state his preference until after he has been elected for appointment

Similarly, if a consultant who is already employed in whole time post wishes to transfer to a maximum part-me contract, or vice versa the board should, before eaching a decision, take his circumstances and preferences ito account again subject to the overriding needs of he hospital service.

This statement does not, of course deal with the many ses where the services of a consultant are needed in the ggregate for only a limited volume of work and where erefore a part time appointment would in all cases be ppropriate.

Public Health

Vaccination in London

At a meeting of the London County Council on April 20 was stated that the percentage (based on live births) of London children under 1 year vaccinated against smallpox hows a steady improvement since 1949 The figures re as follows:

1949	25%	1951	38%	1953	48%
1950	32%	1952	45%	1954	49%

There is continual propaganda on the part of the ouncil's health visitors and clinic doctors to persuade others to have their young children vaccinated General ractitioners are encouraged to take their part in vaccina on and are paid a fee of 5s for each notification sent to e council. Opportunity is also taken to encourage accination by the distribution of literature and display appropriate material in council establishments

Notification of Tuberculosis

A recent Ministry of Health memorandum [1] explains hich medical officer of health should be notified when a erson is diagnosed in hospital as suffering from tubercu sis. Notifications should usually be sent to the medical ficer of health of the district in which the patient ormally lives; but where in the case of long-stay atients, the hospital itself can reasonably be regarded the patient's place of residence the notification should e sent to the medical officer of health of the district in hich the hospital is situated.

Swedish Poliomyelitis Vaccine

s we reported a fortnight ago [2] plans are going ahead Sweden for the use of a poliomyelitis vaccine made growing virus on human tissue Further details have en given in a report by Prof Gunnar Olin of the edish State Bacteriological Laboratory The virus as been grown on aborted human fœtal tissue, and then activated with formalin (1 in 2000 compared with the in 4000 formalin recommended by Salk) The inacti ation is performed at 25 C (the American workers refer 37°C) The antibody response is said to be good hough vaccine has been prepared to immunise 120 000 hildren, but further supplies may be limited by the hortage of suitable tissue for culture American vaccine ay be imported for the time being

Education of Physically Handicapped

The Ministry of Education[3] has found that on Oct 1 951 1052 children were awaiting places in special schools. Their disabilities were as follows: cerebral palsy 485 oliomyelitis 100 heart defects, 78 muscular dys-rophy 73; spina bifida, 68 hydrocephalus, 42 eformities, 40; hæmophilia 20 fragilitas ossium, 20 uberculosis 10; Perthes's disease 12 muscular atrophy, ; rheumatoid arthritis, 3; others 83

Of the 1052 children 202 were awaiting places in day chools and 850 in boarding schools. The existing ducational arrangements for these children were as ollows: 371 were receiving home tuition 250 were n ordinary schools; and 106 were receiving some other ype of special educational treatment (mainly in hos pitals). Of the 725 unprovided for some were not receiving home tuition because of difficulty in finding teachers or of unsuitable home conditions

There appeared to be enough places in day special schools There is still a shortage of places in boarding schools but additional places expected to come into use within the next two or three years should suffice for all children whose parents are likely to consent to their attending such schools

First Quarter in England and Wales

The Registrar General, in his provisional figures [1] for England and Wales in the first quarter of 1955, records a birth rate of 15 5 per 1000 population, compared with 15 9 per 1000 in the first quarter of 1954 The death rate was 15 4 per 1000 population, as against 14·0 per 1000 in the first quarter of 1954 The infant-mortality rate was a new low record for a March quarter—29·0 per 1000 related live births It was 31·0 per 1000 (the previous record) in the first quarter of 1954 The stillbirth rate was 23 1 per 1000 live and still births compared with 23 7 in the corresponding quarter of 1954

Parliament

Disseminated Sclerosis and War Pensions

In the House of Commons on April 20 Mr Arthur Moyle asked the Minister of Pensions and National Insurance to examine the rules and the present terms of the Royal Warrant to see whether ex-Servicemen with disseminated sclerosis might not be assessed at the 100% disability rate—Brigadier J G Smyth joint parliamentary secretary to the Ministry pointed out that in the first world war two-thirds of the casualties were wounds In the second world war the causes of two thirds of the pensionable cases were diseases. But to earn a war pension these diseases must be causally connected with service There was no evidence that disseminated sclerosis was in any way a military disease. The Ministry tried, however, to stretch the regulations as far as they could and where a man had been subjected to a sudden shock, and within a short period showed signs of disseminated sclerosis they said that perhaps the shock, although they knew it had nothing to do with the disease had accelerated its progress and pensions were granted for aggravation Accordingly after the late war pensions for aggravation of disseminated sclerosis were awarded in 1538 cases and there had been 1117 rejections.

QUESTION TIME

Ban on Heroin Imports

In the House of Lords, replying to a question Lord Mancroft said that except for small quantities for purely scientific purposes Her Majesty's Government had decided not to permit the manufacture and export of heroin after Dec 31, 1955 As adequate supplies had hitherto been manufactured in this country imports of heroin had not been authorised for many years: it was intended to maintain the prohibition on importation. The Government had taken this decision in order to give effect to a resolution adopted by the Economic and Social Council of the United Nations at its 18th session, urging all governments to prohibit the manufacture export, and import of this drug except for scientific purposes. Before the decision was reached the advice of the appropriate statutory advisory bodies was taken.

Viscount Elibank Are the Government aware that Dr Arthur Douthwaite senior physician at Guy's Hospital, has stated in the *British Medical Journal* that the banning of this pain killing drug heroin, is an astonishing move which will inflict much hardship upon a multitude of patients? Is the noble Lord aware that one of the best known physicians in Edinburgh, Dr A B Flett has written to me saying it is iniquitous that this most useful, and often, in certain cases really necessary drug should be banned?—Lord Mancroft: The Government are aware of these opinions On the other hand I understand that adequate supplies of perfectly good substitutes for this drug are now available The purpose of the action is, of course to facilitate the world wide banning of traffic in this extremely dangerous drug

---

[1] HM(55)33.

[2] Lancet, April 23 1955 p 857

[3] Ministry of Education: administrative memorandum no. 503 April 25 1955

[1] Registrar-General weekly return no 15 1955 H.M Stationery Office 1 p. 20 1s

I do not think that the Government can do more than follow the technical advice and guidance given by the Central Health Services Council, the Standing Medical Advisory Committee, and the appropriate bodies in Scotland and Northern Ireland

Poliomyelitis Vaccine

Replying to questions, Mr **Iain Macleod**, the Minister of Health, said that a small field trial with the Salk poliomyelitis vaccine was being carried out by the Medical Research Council All vaccine used in this trial, whether imported or manufactured here, would first have been the subject of rigorous tests by the council Plans for large scale immunisation were, of course, dependent on the Minister of Health being satisfied, so far as was humanly possible, as a result of these tests and trials that the vaccine to be used was both efficient and free from danger

Mr **Eric Fletcher** Would the Minister say whether any supplies of Salk vaccine from the Cutter Laboratories have been received in this country?—Mr **Macleod** No Cutter vaccine has been received in this country

Mr **Mont Follick** Are the vaccines which are being made by the Glaxo Laboratories of their own special prescription, or according to a prescription imported from America?—Mr **Macleod** I understand that what they are making is, in fact, the Salk vaccine The difficulties in this case have arisen, I understand, from a batch made by the Cutter Laboratories As we have none from those batches in this country, there should not be difficulty in that particular direction

Salaries of Hospital Pharmacists

Replying to questions Mr **Macleod** said that a general agreement on increased salaries for hospital pharmacists was reached by the appropriate Whitley Council on April 20 Details were now being worked out

General Practitioners in the N H S

Replying to questions, Miss **Patricia Hornsby Smith**, parliamentary secretary to the Ministry of Health, said that on July 1, 1954, 19,300 general practitioners were practising in the National Health Service Altogether 837 doctors practised single handed and 614 partnerships employed assistants, other than trainees The Minister of Health was not prepared to limit the increased number on a list when an assistant was employed to a maximum of 1500 The relationship of principals and their assistants could not readily be regulated by statute

Mr **Somerville Hastings** Does not the Minister realise that many doctors find great difficulty in getting the necessary capital to start in practice and are therefore liable to be exploited by doctors who employ them as assistants?—Miss **Hornsby Smith** The matter is being considered by the British Medical Association and the Medical Practitioners' Union, but we have had no decisions or opinions from them yet

Mr **H Marquand** Does the hon lady recollect that it was a definite promise by the medical profession at the time when the payment to general practitioners was referred to adjudication that they would seek to reduce the number of assistants and increase the number of principals in practice? Is she satisfied that the medical profession are giving real coöperation in this matter as they undertook to do?—Miss **Hornsby Smith** There has been an increase in partnerships and a reduction in the number who do a long period as assistants These consultations are going on between the B.M.A and the M P U and I think the profession are coöperating in this matter where they feel that there is hardship Mr **Hastings** said that the B M.A. committee had already reported and their report was by no means entirely happy about the situation

Replying to a further question, Miss **Hornsby Smith** said that on July 1, 1954, 131 assistants were still in posts which they had taken up before July 1, 1949 Mr **Hastings** Does not the Minister think that this is a serious matter? Even her own figures show that While it is admitted that doctors may derive a good deal of benefit from being assistants for a time, does she not agree that for them to go on year after year in that position, as these figures suggest, is a very dangerous situation?—Miss **Hornsby Smith** I think we should keep this matter in proportion There is a steady increase in the trend towards partnerships Mr **Marquand** Would it not be possible to make an inquiry into this comparatively small number of cases to see what the reason is for this long period of assistantship?—Miss **Hornsby Smith** We will consider that point

Lung-cancer Mortality

Replying to a question, Mr **Macleod** said that the provisional number of deaths attributed to cancer of the 1954 was 16,332 The numbers of deaths so attributed in and 1944 were 2775 and 6684

Mr **Hastings** Does the Minister realise the importance to the health of the community resulting from his pronouncements on this subject some few years ago? Will he consider making a similar pronouncement setting forth the increased knowledge up-to date resulting from research?—Mr **Macleod** I recognise the public anxiety here and I shall be very glad to consider the suggestion

Dr **Barnett Stross** Would it not be true to say that whatever may be the cause of this disease—and many people now suspect what may be the cause—it cannot be the ingestion of any foodstuffs that is causing the rise in cancer of the lung for it would affect women as well as men, and that it does not do?—Mr **Macleod** Whatever may be the reason, it is true that the increase is very much more—indeed it is more than twice as great—amongst men than women, which would seem to indicate a special cause

Child's Treatment in Hospital

Mr **Kenneth Robinson** asked the Minister why a boy aged 10, who was admitted to Hampstead General Hospital on March 30 with a fractured and dislocated arm, received no medical attention for more than six hours, during which time he was offered neither food nor a sedative—Mr **Macleod** replied I am very much afraid that the facts are as stated and it is clear that the hospital staff failed grossly in providing proper attention On behalf of the board of governors and myself I must apologise to the child's parents I assure them that the board take a serious view of the whole incident and that those responsible have been severely reprimanded

Mr **Robinson** Whilst I welcome the Minister's admission of the responsibility of the board of governors for this matter, and, of course, accept his assurance of regret does he not agree that the public has been led to expect that the teaching hospitals should set a standard of conduct in these matters, and does that not make the incident even more deplorable?—Mr **Macleod** No doubt that is true I am bound to say that the only thing I welcome about this case is that the hospital at once admitted an error As we know errors happen in the hospital service I deeply regret that this should have happened, and my views have been put very strongly to those concerned Mr **Hastings** Will the Minister make it quite clear that it is his desire that at every general hospital there should be a medical cover throughout the twenty four hours, and that so many doctors should not be away from their work as at present?—Mr **Macleod** It is certainly desirable that wherever possible cover should be provided, if not on a twenty four hour basis, at least urgent and near

Requests for Lists of Patients

Replying to a question, Miss **Hornsby Smith** said that the Minister of Health was not aware that political party organisations were asking doctors for lists of patients for the purpose of the postal vote at the general election

Mrs **Barbara Castle** I have in my possession circular letters from Conservative associations to local doctors in their areas asking them to supply the Conservative party with the names of blind, sick, and aged patients on their registers in order that they may be contacted with a view to their having a postal vote Will the Minister institute an immediate inquiry and inform the doctors that this is contrary to professional etiquette and their duty to their patients?—Miss **Hornsby Smith** If the hon lady will let the Minister have the evidence I can assure her that he will look into the matter The vote is secret and in their individual capacity it is certainly helpful to see that as many as possible obtain their vote

Mr **Herbert Morrison** Will the hon lady on behalf of the Minister give an assurance that neither directly nor indirectly will those associated with the National Health Service be coöperators with any political party organisation in connection with the forthcoming election? Is she aware that there was the strongest impression at the last election that such malpractices took place?—Miss **Hornsby-Smith** I can certainly give the assurance that the Health Service will not be used in this way

Replying to further questions, Mr MACLEOD said he would look into this matter at once Whether he would make a statement on it would depend on the results of his inquiries.

Orthodontic Treatment

Replying to questions Miss HORNSBY-SMITH said that the number of courses of orthodontic treatment approved under the National Health Service for 1040 was 12 000 and the payments made were £300 000 The figures for 1954 were 48 000 and £500 000 Orthodontic treatment was provided under the hospital and specialist services, the school health service and the general dental services. The number of dentists in England and Wales who in 1954 were each given approval to start more than 100 courses of orthodontics under the general dental services was 42

Medical Examination of Broadmoor Prisoners

Mr T E DRIBERG asked the Home Secretary if he was aware that a medical report by the principal medical officer of Brixton Prison dated Feb 14 1953 stated that a prisoner was sane and fit to stand trial on a charge of attempting to murder his wife and recommended him as suitable for voluntary treatment in a mental hospital; that at his trial five days later this man was found guilty but insane and ordered to be detained during Her Majesty's pleasure and that he is still detained at Broadmoor where his wife and other relatives had found him in apparently normal health and if in these circumstances, he would allow an independent medical examination of this patient.—Major LLOYD GEORGE replied The responsibility for deciding when a Broadmoor patient is fit to be transferred or discharged rests on the Home Secretary and my predecessors and I have consistently taken the view that the expert staff of psychiatrists at Broadmoor who have the patient under constant observation are in a better position than an outside doctor to advise the Home Secretary on the patient s mental state and future prospects. The answer to the last part of the question is, therefore No Sir

Mr DRIBERG Is the Home Secretary aware that Dr Mathieson, of Brixton, also said that this man was suffering simply from a mild anxiety neurosis, which should yield to proper psychiatric treatment but that since he has been in Broadmoor he has had no such treatment whatever? It is obviously impossible for the very efficient and conscientious staff at Broadmoor to give proper psychiatric treatment to the very large number of patients with whom they have to deal In the circumstances, will the Home Secretary consider either getting an independent opinion or transferring the man to a mental hospital where he can be treated?—Major LLOYD GEORGE: These cases are very difficult I am aware of the opinion to which the hon Member has referred and I have of course gone into the case myself with great care On the information I have I do not think anything can be done But I am prepared to look at the matter again and I will do so

Motoring Offences and Blood Tests

Replying to a question, Sir HUGH LUCAS TOOTH, joint under secretary of State to the Home Office said that during the last year no motorist charged by the Metropolitan Police with being under the influence of drink while in charge of a car had requested a blood test but in one case samples of blood and urine were taken at the request of a doctor called on behalf of a person who had been arrested for such an offence

Mr SOMERVILLE HASTINGS: Does the Minister not agree that this test which has been largely used in other countries, might usefully be *tried* out in this country so that some idea could be obtained of its real value? At present its value seems to be somewhat uncertain. Will the test be made possible for those who apply for it?

Sir HUGH LUCAS TOOTH: Opinion about the value of blood tests in these cases is sharply divided, and it would be inappropriate for me to express a view either way at the present time Research on the effects of alcohol upon driving performance is being carried out by the Medical Research Council and the Road Research Laboratory

Mr R. R. STOKES: Have not the police chucked this bit of nonsense as being absolutely unreliable?

Replying to a further question Sir HUGH LUCAS TOOTH said that the provisional figures showed that in magistrates courts in England and Wales there were during the first nine months of 1954 1051 convictions of driving or being in charge of a motor vehicle while under the influence of drink or drug The number of resulting sentences of imprisonment was 112

In England Now

A Running Commentary by Peripatetic Correspondents

THEY say a psychiatrist is a man who goes to the Folies Bergère to look at the audience, so I went to the Private View day at the Royal Academy The trouble about Private View day is that you get trampled underfoot by people with one eye on the pictures and the other on the look-out for their friends But still, it has the advantage that the ladies hats are more surprising than they are on other days, and the girls seem prettier and you can watch the artists being casual about their masterpieces They have a variety of techniques for this. I heard one ask, in incredulous tones, ‘ Do you mean you *like* it? but whether this was modesty, or surprise that his audience appreciated it, I could not tell. Then I like to see the subjects standing sheepishly near portraits of themselves. I am one of those people who do not get much further in Art than knowing what they like, but I did like the portraits this year there were several startlingly good ones and very few of those others. I liked the one of the toy monkey because he unlike most of the other sitters, was not pretending to be blase about having his picture painted There were, of course, the usual dreary people sitting in dreary rooms, but I wonder how Charles Spencelayh manages to make ordinary objects so exciting? I suspect that the secret lies in the title he has given to one of his groups—*God's Good Things* Perhaps it is because I like bouncy dogs, but I was intrigued by *Whippet* in terra cotta, who had curly ears and a curly tail and was very much alive ‘ And ducks are soothy things, and lovely on the lake That was another lovely thing in oak, a mother duck obviously telling her brood a bedtime story Exciting in a different way is a statue of a nun, with severe straight lines except for her face and expressive hands. There is so much too much, to take in as always The biggest crowd was consistently round what has now come to be known as the Annigoni of the Queen For the record the most frequent remark I heard in the whole exhibition was The traffic my dear, was simply frightful.

* * *

My medical wife and I discussed the mushrooms fully Growing they were pleasant-looking things and after consulting the encyclopædia we convinced ourselves that they were edible We ate them for breakfast the following day and I had a large helping which tasted delicious with bacon My wife drove me to the hospital where I sat down in the office to attend to some routine papers Some thirty minutes after breakfast the odd feeling started I found it difficult to concentrate on my work and noticed a transient diplopia which could be mastered only by an effort. I experienced a curious sensation of being in the room but apart from my body The voice of someone speaking in an adjoining office seemed a great distance away Of course this disturbed me but the probable cause eluded me for a while. Then—The Mushrooms! I grabbed the phone and with some difficulty dialled my home. With great relief I heard my wife s voice, though it was slurred and not too intelligible. In the brief moments of waiting for her to answer I had an awful vision of her having crashed the car on the way home. She too felt very odd and had just realised why By this time I was getting a bit disorientated but I sent one of my colleagues off to bring my wife my daughter, and the lodger into hospital I then floated rather than walked up to the ward for a stomach pump session. I was given atropine and intravenous glucose and rapidly felt better

My wife who was not treated so soon became quite confused and went into a state of shock before she reached hospital but fortunately retained enough presence of mind to insist on picking up the lodger from her office on the way The three of them were then treated as I was, to the intense indignation of daughter aged eight who had eaten only one small mushroom and felt quite well They too improved rapidly, but my wife remained mildly shocked for several hours

I found it impossible to get the fungus identified but assumed that it was one of the types containing a mus carine-like alkaloid—possibly *Inocybe patouillardi* I don't think it could have been *Amanita muscaria*, which from its pictures seems a distinctive fungus quite unlike our specimens

The story spread rapidly and, needless to say, such an occurrence in a medical family was the cause of much ribald comment The loudest laugh was enjoyed by my son aged twelve who doesn't like mushrooms and who refused them on this occasion because he didn't like the look of them His big moment came when he poked his head into my hospital room and said "I told you so!"

* * *

Some of our West End colleagues still bemoan the loss due to war, the B B C , and Big Business, of the Langham, and now the Bolivar—its posteriorly situated vestigial remnant—has suddenly closed its hospitable doors It is heart-rending to see thirsty pillars of our profession being caught out by padlocked doors without so much as a "closed" notice on them I saw one famous man nip round the corner to check his watch against the All Souls' clock before the devastating truth dawned upon him Where consultants' fluid-balance and milli-equivalents can conveniently be put in order now, goodness only knows What with this calamity and the Med Soc Lond having no visible means of support at its northern end, Chandos Street is not what it was

* * *

Those who heard Pierre Monteux conducting the Royal Philharmonic Orchestra at the age of 80 must have marvelled at his apparently limitless energy Bruno Walter, one year younger, is to take command of the B.B C Orchestra this month It is only a few years since Toscanini, now 88, electrified us all at the Festival Hall Vaughan Williams, at 83, would probably call himself an amateur conductor only Weingartner, Mengelberg, Richard Strauss, and Kussevitzky were all around, or well above, 80 when they died in full harness Sir Thomas, of course, is a mere stripling at 75 , he, Cameron, and Ansermet are a trio of active septuagenarians Sir Henry Wood had hardly shed any of his habitual load of work when he died at 75

It is fortunate for the rest of us that these eminent maestros enjoy such long spans But why do they? Is it because, unlike most surgeons and professors, they keep on working? Or are eminence and longevity associated irrespective of occupation? Quite apart from ex-prime ministers, Augustus John and Brangwyn are well into their eighties , Sir Gerald Kelly and Sir Alfred Munnings are in their late seventies

A famous but still relatively young conductor once told me that, while in action, he felt "the vital juices flowing down the arms to the heart" Perhaps he was right , perhaps the apparent immunity of orchestral conductors to the more spectacular forms of cardiovascular collapse is due to the fact that they wave their arms about a good deal

* * *

How much we suffer from failure to convey our wishes correctly to our patients Listening to one's colleagues shows how much time and effort are wasted by lack of liaison -

"Lie on your back on the couch—No, on your back, please"

"Show me where the pain comes—No, on your own back please"

"Please stand up—now, raise your right leg—thank you, and now your left leg—thank you, and now get up off the floor"

There is clearly an urgent need to revise the technique of medical questioning, and at the next twelve unselected outpatient clinics we are giving a trial to the following phrases

"Lie on the couch with your tummy upwards"
"Show me on your own back where the pain is"
"Bend your knee crooked—and now bend it straight"

I would welcome suggestions how to avoid the inevitable contraction of the calf muscle just as I withdraw the tendon hammer from my pocket "Relax," "Pretend you're asleep," "Don't bother about me," "Go loose," and "Pretend you're dead" have been tried and found wanting

Letters to the Editor

HASHIMOTO'S STRUMA LYMPHOMATOSA

SIR,—Independently, we have each been interested several years in Hashimoto's "struma lyphomatosa" 1953, again independently, we obtained marke abnormal liver-function tests in some of these cases, finding of which we have seen no previous record, and which one of us drew attention in your columns year[1] This mutual interest came to light when we by chance on the slopes of a Yorkshire mountain, not having met as colleagues for over twenty years intend to record our findings in full in due course but preliminary details may interest your readers

Owing to a difference of approach there is some of uniformity in our case records, but we are agreed the main observations

(1) The presumptive diagnosis is essentially clinical the condition is commoner than is generally suppos Although there are certain typical features, includ preponderance of cases in middle aged females, sympto of subthyroidism of variable degree, and a thyroid easily felt and abnormally firm, we would stress that infrequently the patient first visits her doctor for symp toms not quickly ascribed to thyroid disturbance, as lassitude, muscle and joint pains, increasing weig and changed facial appearance The efficacy of mode treatment by oral dried thyroid emphasises the need the diagnosis of Hashimoto's disease to be consider more readily We have studied about 25 patients, nearly two thirds of whom the diagnosis has confirmed by surgical section

(2) The basal metabolic rate is subnormal in most the patients when first seen, but a minority in the stage show signs and symptoms of hyperthyroidis Anæmia is not a characteristic feature

(3) The liver function test most consistently abnorm in the untreated patient is the colloidal gold te thymol turbidity and flocculation tests generally parallel with it In a few patients the serum alka phosphatase is slightly or moderately raised Th bromsulphalein test may be abnormal, but the galact tolerance has been normal in the 5 patients exami After treatment by dried thyroid gland, the liver-func tests in some patients return to, or towards, nor within a period of months, but in others the return much slower and we have seen the tests still gro abnormal after more than two years Electrophor shows a raised and abnormal serum-globulin level in few patients In general, however, there appears to no close relationship between the results of the flocc tion test and the plasma cholesterol, or the bas metabolic rate

(4) We suspect that gross liver disease may arise struma lymphomatosa One of our patients, observed seven years, now has a liver which is greatly enlarg and abnormally firm, and a palpable spleen The sple is palpable in 2 of 17 other patients In the 1 patient whom surgical biopsy of the liver has been poss however, the histology was normal

(5) We have not yet seen such gross changes in th liver-function tests in typical primary myxœdem although lesser degrees of change have been observed.

(6) We are impressed by the steady diminution the size of the thyroid gland during treatment by dr thyroid , this point is not mentioned in the literatu but it was emphasised by Crile in his Moynihan lectu to the Royal College of Surgeons in January, 1954

STAPHYLOCOCCAL INFECTION IN THE NEWBORN

ir,—We fear that others, like ourselves may interpret paper by Dr Forfar and his colleagues (March 19) simply as a clinical and bacteriological study but as a ommendation that all infections in newborn babies in ternity hospitals should be treated with erythromycin feel that such a recommendation would be misguided we should like to comment upon it The clinicians ongst us made the mistake of adopting just such a icy some years ago and we have lived to see its fortunate long term consequences We have also rnt more about the nature and dangers of staphylococal infection in the newborn as a result both of close llaboration between clinicians and bacteriologists and more critical clinical observations in our hospital during past few years We accordingly reversed our previous icy some time ago, and have as yet had no cause to ret this decision The fact that the antibiotic with ich we were concerned was penicillin not erythrocin does not appear to be relevant since as Forfar d his colleagues admit, there is evidence that sooner later staphylococci become resistant to erythromycin

For us the crucial fact is that the more frequently the phylococci in a particular community are exposed to a ticular antibiotic, the more likely are they to become istant to that antibiotic. If there were any overriding vantages to be gained by using an antibiotic as freely Forfar and his colleagues recommend the inevitable advantage would have to be accepted But although y state that "Edmunds et al (1955) show that early gnition and early treatment of minor staphylococcal ction in the newborn play an important part in venting serious sepsis" we can find no evidence atever to support this statement in the paper to which y refer[1]

We have not treated any case of skin sepsis when t seen during the past twenty months unless it was extensive pustular rash in a small premature baby, we had other grounds for believing that the baby ill

uring this period 163 cases of skin sepsis have occurred tules and paronychiæ): 11 were treated from the start use of one of the indications we have mentioned 11 e treated later because the local lesions were extending r a period of forty-eight hours observation and the aining 141 cases (86%) received no treatment of any kind n they remained well and the local lesions were clearing or cleared after forty-eight hours.

During the same period of twenty months virtually all s of sticky eye developing after the first twenty four rs of life were treated simply by local instillation of 10% phacetamide The cases which developed within the first nty four hours were left untreated unless they failed to lve spontaneously during a period of forty-eight hours ervation because we know as a result of earlier work in this spital[2] that a *Staphylococcus aureus* can be cultured from than 10% of these early cases. Altogether 470 cases of ky eye were recorded during the twenty months.

We should like to mention that no serious infection of y kind (pneumonia, osteitis &c) developed in any of e 633 babies suffering from a superficial infection and ated on the conservative lines we have indicated

We did encounter a serious infection during this riod in a baby who died of a staphylococcal pneumonia the thirteenth day of life but there was no clinical perficial infection in this baby at any stage We also d to use a systemic antibiotic on a number of occasions cause a baby appeared to be ill and probably infected the absence of any minor superficial infection whatever We feel that this experience supports our present licy of restricting the use of all antibiotics to an absolute minimum since it has shown that this is not only desirable in theory but also safe in practice The real indication for antibiotic therapy seems to us to be a clinical diagnosis of systemic infection (with or without superficial sepsis) This indication is uncommon, but an effective antibiotic must be used at once in these circumstances and this is an urgent matter on which the baby's life may depend We feel that our chance of being able to use any particular antibiotic with confidence (before the sensitivity of the organism from the particular case is known) depends upon our past conduct in relation to that antibiotic. We are very glad to be in a position to keep erythromycin in reserve for the case that really needs it and whose life may very well depend upon it and we would like to think that others were exercising a similar restraint We cannot understand what has prompted Forfar and his colleagues to reverse the much more selective policy which they outlined in 1953[3]

ACID-FAST BACILLI IN ACHALASIA OF THE CARDIA

Sir,—Dr Davies and Dr Roberts (April 23) rightly emphasise the need for critical assessment of the finding of acid fast bacilli in the sputum in cases of achalasia of the cardia with respiratory symptoms A diagnosis of pulmonary tuberculosis may wrongly be made if such organisms are not cultured

Acid fast saprophytes are not uncommon findings in sputa in a number of other chronic pulmonary diseases and it is doubtful if they play any important rôle in them. In the lipoid aspiration pneumonia of achalasia of the cardia however, these organisms may act as pathogens and the bacteriological findings must not be summarily dismissed A fatal infection of this nature and a review of the subject has been published[4] Although mycobacterial strains freshly isolated from such cases generally show an unusual virulence for experimental animals especially mice it is the modification of the host's response brought about by the presence of fat in the pulmonary alveoli coating the organisms that appears chiefly responsible for the resulting illness. The cultural characters of the strains isolated vary from case to case and so these pulmonary infections differ from some of the recently reported non tuberculous mycobacterial skin infections such as that due to *Mycobacterium balnei*[5]

A BARBITURATE ANTAGONIST

Sir —I have read with interest the letter of Dr Morgan McElligott (April 16) in which he reports no change other than a deepening of respirations after the administration of 240 mg of ββ methyl-ethyl glutarimide ('Megimide') to a patient who had taken gr 72 of phenobarbitone Dr McElligott is not quite correct in thinking that the lack of clinical improvement was due only to insufficient dosage Certainly the dose for this case would have been 1 0 g and probably even then the patient would have regressed and required one or two treatments more But the important point is that treatment was not started until *six* days after admission

Megimide appears to be a specific antagonist to barbiturates. At the end of six days there would be little barbiturate in the body By this time however, there would have been extensive cellular damage—e g, cerebral œdema—and one would not expect any drug to reverse this injury

---

A VISIT TO KOLTUSHI

SIR,—Mr Ruscoe Clarke and Dr Leonard Crome (April 2) write that the objective of study at Koltushi "*was an understanding of the functioning of the organism in its unity with the environment*" They state that among the "general principles" used at Koltushi one was expressed in the statement "Descartes knew already that environmental factors determine the functioning of the organism by means of reflexes" In their conclusion, they state that they "had no more than a glimpse of the new science" They ask "was it a glimpse into the future?"

We are entitled to ask whether a science based on the study of the "conditioned reflex" is so new Is it a study likely to provide the kind of future we should all desire should come about? In his introduction to *The Use of the Self* by F Matthias Alexander, the late John Dewey wrote in 1932

> "The school of Pavloff has made current the idea of the conditioned reflex Mr Alexander's work extends and corrects the idea It proves that there are certain basic, central organic habits and attitudes which condition every act we perform, every use we make of ourselves This *discovery corrects the ordinary conception of the conditioned* reflex The latter as usually understood renders an individual *a passive puppet to be played upon by external manipulations* The discovery of a central control which conditions all other reactions brings the conditioning factor under conscious direction and enables the individual through his own coördinated activities to take possession of his own potentialities It converts the fact of conditioned reflexes from a principle of external enslavement into a means of vital freedom."

Mr Alexander enables a person to provide for his use a self acting as a unity with its environment by the following procedure

> The person inhibits his habitual *reaction* to a stimulus Thus he allows the head to go forward and up This sets in motion an innate reflex whereby the self as a whole instead of firstly directly reacting to its environment indirectly firstly acts as a whole outwards on the environment in all directions in the greatest possible degree Thereby the integrative action of the central nervous system is given freedom to work at its best Thereby the person is provided with a unified whole self he may use for reacting to his environment with kinæsthetic information about his guidance of his actions working in the best way

Bolton, Lancs MUNGO DOUGLAS

ARGININE DEFICIENCY AND MALIGNANT DISEASE

SIR,—I noticed an abstract of a paper by D L Horrigan [1] reporting the excretion of uracil in 3 out of 5 patients suffering from myeloid leukæmia It occurred to me that there might be a possible connection between this observation and the finding [2] that the growth inhibition of a micro organism by uracil was prevented by arginine It may be that uracil encourages malignant change by suppressing the growth of normal cells rendered arginine deficient by the invading neoplasm, which then grows at their expense The simplest test of this hypothesis would be the administration of arginine in cases of experimental or human cancer

As a microbiologist I am not equipped to make tests, but some of your readers may care to co the possibility

Banstead, Surrey E J MILLE

REGISTRARS AND REGISTRARS

SIR,—I am a little surprised to read in your lett April 23 so embittered and venomous an epistle as signed by Registrar (W plus) The writer's ignorance military ranks *seems equalled by his lack* of know of teaching hospitals If by any chance he is likely become a "*failed registrar*" he may perhaps be ab take shelter under the Strachan umbrella

London, S E 1 J J CONYBEA

SIR,—Registrar (W plus) has raised a subject of interest to all registrars One point which req further stress in the inequality of duties is the fact the same difference in the amount of work done *registrars also exists in the teaching, but non profe* units

There are many registrars (W plus) working in tea hospitals—not only in peripheral hospitals, as correspondent suggests The group he describes as re trars (T) undoubtedly exists *in professorial units.* T add little or nothing to the every day (and night) run of a hospital service, but they use the time and facil to acquire further qualifications, and write nume papers On these achievements they are often elev *to consultant status in preference to registrars* (W with a wealth of practical and useful clinical knowle and experience

Of course, many of these experimental studies are considerable value, but it is unfair, with the ever incr ing expense of the National Health Service, that expanding number of hospital staff should be secluded *this type of work, whilst others of equivalent* st provide a 24 hour hospital service Clearly the pro time for writing theses for higher degrees and pub ing articles is when one has sufficient knowledge experience *to write with authority on the* subject *one's choice At the moment many higher degrees* obtained by men working in a laboratory on a su chosen and supervised *all through by their chiefs*, finally examine them Unfortunately in the keen comp tion for obtaining a consultant post, higher degree count, but in reality are these higher degrees of any clinical value? I doubt it!

REGISTRAR (W

PROTECTING THE MOTORIST

SIR,—There can be no doubt that in the near fu motorists will be more willing to use safety dev *against motor car accidents* Crowding on the r plus a high proportion of fast cars will ensure this

Most car accidents are preceded by a second or of warning During this period the natural reaction behaviour of most passengers can be imagined with description

May I propose the following emergency drill passengers, for consideration by *those* who h opportunity for experimental examination of the r or who have clinical experience of the type of inj in question? This drill is specifically designed to av injuries to the head and face when passengers are f *forwards against the windscreen*

The feet are raised and pressed against the d board or against the back of the front seat *in the* c of rear passengers The hands are cupped under t chin, the elbows being wedged in the groins This w prevent whip lash strain of the neck

If this method were to gain medical approval, it ma be possible to include it in the *Highway Code*

Hornchurch, Essex I H J BOURNE

MEDIAN-NERVE PALSY AND ACUTE INFECTIONS OF THE HAND

SIR,—May I add a similar case to those described by Bailey and Mr Bolton Carter in your issue of rch 12? It is one of 42 cases of carpal tunnel syndrome ated during the last four years, upon which a report now being prepared

A butcher aged 49 was seen on July 7 1953 with a pulp ction of the right thumb which had been drained two s previously He had had systemic penicillin for one y before incision and for the next two days, and this was tinued He had much pain in the hand and wrist avated by extension of the fingers, which were held in the ition of rest Movement of the middle and ring fingers greatly restricted the index and little fingers less so e thumb could be moved more freely but this caused some n. Pain at rest was in the median nerve distribution l was severe enough to keep him awake There was tender s on the palmar aspect of the hand over the carpus and t joint with diminution of sensation of light touch but pin-prick over the median nerve distribution in the hand. dorsum of the hand was considerably swollen.

For the previous eighteen months he had had pain in right hand with acroparaesthesiae in the distribution of the dian nerve every Friday night which had repeatedly ken him. On Saturday mornings the hand was stiff and b with limited finger movement and some residual gh lessening pain this subsided completely by midday Saturday not to recur until the following Friday night. se symptoms had become progressively worse until he had ely been having pain on occasional nights during the week ficient to awaken him (Butchers are busy in South tralia on Fridays, because they have to prepare large ers for the weekend for a population that eats a lot of at and they do not open on Saturdays.)

In spite of continued penicillin and rest in a plaster back b with elevation, the hand grew steadily worse the fingers re immobile and their movement more painful, until lly he could have no finger moved passively into extension hout great pain Sensation loss by July 11 was complete light touch and much impaired to pin prick over the median ve distribution. Tenderness at the wrist was much reased.

Decompression of the median nerve was therefore done July 12 by longitudinal incision through a convenient mar crease The flexor retinaculum was divided fully nerve was found to be swollen and reddened in the ximal half of the carpal tunnel and relatively narrowed dark red in its distal half A little serous fluid was present there was no abnormality of the tendons. The skin was rly sutured and it healed well Convalescence was slow satisfactory He was back at work in four weeks, although ory loss and strength of the hand did not recover fully four months.

On April 18 1955 he said that he has had no trouble since, hand has remained normal, and his working capacity is mpaired The scar is supple pain free and hardly visible

I feel little doubt that the infection caused an inflam tory swelling in the carpal tunnel which converted a odic occupational carpal tunnel syndrome into a ative emergency I think it probable that Mr Bailey d Mr Bolton Carter's cases fall into the same category

In case 1 there was a history of rheumatism in the ds which may well have been a carpal tunnel syndrome d they mention osteo arthritis in the left hand, which in the es may be a factor in the production of the syndrome case 2 there is no mention of previous history but it is possible that inquiry might reveal that the patient d previous symptoms of median nerve compression Both these patients fall into the age and sex group most commonly cted by carpal tunnel syndrome—i.e., women at or out the time of the menopause Case 1 had been having ptoms for years and these probably first arose at the time the menopause.

In both of these cases the early and marked loss of sensation is particularly interesting As well as the butcher I have en it in one other patient—a man with a severe carpal jury and projection of part of a fractured lunate into the pal tunnel His flexor retinaculum was divided and the jecting bone removed three weeks after the original injury but by that time he had complete anaesthesia over the median nerve distribution in the hand which took six months to recover There was acute tenderness over the median nerve at the wrist but apart from some loss of finger movement by mechanical interference, there was little motor impairment.

The restriction of finger movement in all these cases must be due to mechanical interference in the carpal tunnel by compression of the tendons. The dominance of sensory loss seems to be a feature of the more acute lesions in the usual and much less acute carpal tunnel syndrome wasting of the thenar eminence and weakness usually come before definite sensory loss Such patients, however often complain of numbness at the finger tips, especially in the early morning which interferes with knitting and sewing

I agree with Mr Bailey and Mr Bolton Carter that the compression in their cases was the result of inflammatory exudate and consequent ischæmia of the median nerve, but I think that there was a pre-existing lesion which narrowed the carpal tunnel, predisposing to the nerve compression This may in some cases be a stenosis comparable to De Quervain's disease or some other factor possibly hormonal but whatever the predisposing factor the median nerve lies in the carpal tunnel in a particularly vulnerable position In none of my cases has any disability resulted from division of the flexor retinaculum This is not surprising in view of the fact that all strong movements of the human hand occur with the wrist in extension The flexor retinaculum in man seems to be a useless structure

I was interested to read that Mr Bailey and Mr Bolton Carter required a longitudinal palmar incision to be sure of adequate exposure and division of the flexor retinaculum I have tried the transverse wrist incision found it inadequate and reverted to the longitudinal. There are objections to this incision, but in practice they all heal rapidly and well with no disability, especially if carefully made in a crease.

As soon as the diagnosis of median neuritis from compression has been established I make it a rule to divide the flexor retinaculum as soon as possible to avoid the chance of irreversible damage to the nerve. The only exception to this rule is in menopausal women with mild symptoms, which may sometimes be completely relieved by œstrogens. But should there be no improvement within a short time the rule still applies

IRON DEFICIENCY ANÆMIA IN PREGNANCY

SIR,—The question of iron therapy in pregnancy is a topical one and articles such as that by Dr Gatenby and Dr Lillie in your issue of April 9 are very helpful in dealing with the practical aspects of this subject

May I make one or two comments on points made by them? It is true that there is a high incidence of intolerance to the ordinary ferrous-sulphate tablets but I have hardly ever found intolerance to enteric-coated ferrous sulphate tablets, so it is to this form of therapy I turn when the former fails. The enteric coated tablet costs only about double the ordinary variety Ferrous gluconate, however I am told costs about ten times as much as the simple ferrous-sulphate tablet This may be worth considering It is true that some might argue that there is a danger of the enteric-coated tablet passing through the gut undissolved especially as the ordinary tablet passes a long way (as demonstrated radiologically) However the clinical response appears to be adequate, so I am not unduly disturbed by this

Another point is in connection with parenteral forms of iron therapy, so widely used now Why should an anæmia discovered late in pregnancy be an indication? All the evidence I have seen shows that the response to oral iron should be as quick as to parenteral iron[1] A quicker response, then, cannot be claimed If one ensures that the patient can take, and is taking, her oral iron, by asking her a few days later, then intolerance of oral iron is no argument Finally, I believe that a form of iron-deficiency anæmia which fails to respond to oral iron is very rare indeed Most of these cases will prove to be megaloblastic if a sternal marrow examination is made

MADE-UP WORDS

SIR,—" Bibliotherapy " indeed[1] ! How long are we to tolerate this pompous, humourless, self-important use of long made up words to describe such a simple procedure as providing helpful books for a child or his parent to read ?

RADIOLOGY OF PLACENTA PRÆVIA

SIR,—Dr Blair Hartley is doing excellent work in using his special technique for visualising radiologically the *calcified* placenta in localising its position This, he told us in his letter of last week, he can do in rather less than 1 in 3 cases Just in case there are some, among the many who I hope will read his letter, who have not yet been sufficiently convinced of the undoubted merits of ordinary soft-tissue placentography to take it up, I feel I must reassure them that it is quite unnecessary for calcification to be seen in order to determine the placental position

Dr Blair Hartley says that seeing the calcified placenta is factual evidence , agreed, but it would be a pity if those still hesitating to adopt soft tissue placentography became so disappointed at their failure to *see* the placenta in over two thirds of their cases that they did not finally adopt it and thus denied to themselves and their patients the great advantages of the method

FUNCTIONAL SYMPTOMS IN ORGANIC DISEASE

SIR,—In the final paragraph of Dr Barham Carter's somewhat breezy article last week, there occurs this sentence " The great tragedy, of course, is to miss the organic "

It is surely sad that in 1955 it still needs to be pointed out that this attitude reveals a long out dated overvaluation of the soma, and that the tragedy of missing the psychogenic is neither less nor greater but exactly equal to the tragedy of missing the organic

Thirteen years ago an article appeared in *The Lancet*[2] entitled Neurosis Simulating Organic Disorder This dealt with 50 cases which had been referred by Army doctors to an E M S hospital with a definite diagnosis of organic disease, and in which the condition was ultimately found to be purely psychogenic Any case in which even the suggestion of nervous disorder had been raised was excluded from the series

34 of these patients had been admitted to the medical and surgical wards, and constituted 20% of the hospital intake for the 3 months covered by the investigation ,

8 of these patients had spent between them 96 weeks in various hospitals and 106 weeks on light duty ,

19 of these patients had between them been radiographed 30 times, including 12 barium meals, 2 barium enemas, and 2 intravenous pyelographies ,
